Peach house.—Peach-trees require a great deal of water during their season of growth, and particularly while the fruit is swelling, apply it in a tepid state. In regulating the young shoots, do not get into the common error of laying in too many. Stop those shoots that are growing too strong, when about six inches in length, and repeat this frequently through the season, that the weaker shoots may be benefited by it.

Fig-house.—If any of the trees have failed to produce fruit in the early house, and the cause appears to be an over-vigorous state of the tree, which is very often the case, root prune them now, and you may have a good crop in the autumn. No plant does better from root-pruning than the Fig, and the operation may be performed at any season, if dull weather is chosen. The shoots will be shorter, and better ripened after it, and a crop is almost certain.

Strawberries.—The plants in pits and frames may be removed to the shelves, near the glass in a Vinery or Peach-house,

taken up the fruit is set, and their places filled with successive plants. Place pans under the pots on shelves, as they suffer much if allowed to become dry.

Melons.—Those who have pits should grow the Persian and the new Cabul Melons, as they are very superior in flavour, and bear freely. They should be planted out in front of the pit, and need not be stopped like other Melon plants; train the leading shoot up under the centre of the lights, and the laterals from each side at right angles.—*G. F.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Fruit-trees, Currants, &c.—Take every favourable opportunity to finish pruning, nailing, and washing or painting, all sorts, with the exception of Peaches and Apricots.

Onions.—If a quantity of the autumn-sown are transplanted properly, better bulbs will be procured than from those left where sown: where there is a deficiency of these, sow in a slight hotbed, more especially where young Onions are in demand for salads.

Potatoes.—Throw up some ground in ridges in a warm situation, two feet apart, to be ready for planting when fine dry weather sets in. The Ash-leaved Kidney is the most general favourite. To keep it healthy and vigorous, expose a quantity of the tubers from an early crop before they are ripe, to the sun and weather, until they become quite green, and there will be no complaint of weakness, curl, &c. Failures often proceed from the tubers being too ripe, and from being heated in pits, &c.

Mushrooms.—Attend to beds in a bearing state. Allow no spawn to run into the covering material, or along the surface of the bed. If, from examination, you find the bed getting dry, pour water into holes made every eight inches with a small pointed stick; though you may have plenty of spawn in the centre of the bed, yet if it is too dry, or has to come through a considerable thickness of material which is too wet, you will obtain but few Mushrooms. In making fresh beds, if you find the material too wet, before inserting the spawn, wrap each piece in a handful of dry litter. If you are fortunate enough to get the material too dry at this season, after inserting the spawn, slightly damp the bed and cover with a coating of cow-dung quite wet. The principle aimed at in both cases is similar—the insuring a fit material for the spawn to work in, and the surrounding that material with a rich moist substance, to give the Mushrooms flesh and consistence.

Routine.—Turn up all spare ground, protect frames and pits as heretofore.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—The works previously recommended should be proceeded with at all convenient times.

Coppice.—In some Coppices there are very old stools, from 1 to 2 or 3 feet high, from previous cutting. It would be of very great benefit to cut such stools off close by the surface with a saw or axe, making the cut with a gentle slope upwards, from one or both sides, according to the size of the stool. I have seen neglected Coppices wonderfully improved by this method.

Young Plantations.—Continue to proceed with thinning and training the young trees, filling up vacancies with young plants where any have failed, and planting Evergreens and some other things, such as Beech or Hornbeam, which retain their leaves through the winter, to be headed off, and kept as shrubs, in Plantations where a permanent undergrowth is required, and not designed for Coppice. Repair the fences, and proceed with all other necessary work; go over Plantations made in the autumn, and firm the soil about all small plants that have been lifted up by frost or loosened by wind. Do this as soon as the danger of severe frost is over, performing the operation when the ground is moderately dry, before drying winds prevail or the sun becomes powerful.

Hedge rows.—The making and repairing of fences and planting trees should be completed as soon as possible. But hedges, like most trees and shrubs, make more vigorous shoots if they are not after the sap is fairly in motion.

Nursery Work.—All young plants, either in the seed-beds or in rows, that are to be removed this season for planting out permanently, or to be placed in rows for future planting, should be taken up and laid in by the heels in well pulverised soil before the sap gets in motion. Proceed with all possible haste to finish all planting for this season, especially in dry ground and early localities; in cold wet bleak situations there need be no great hurry, for plants generally succeed better in such situations when they are planted after the frosty weather is over. About this time also, any cuttings or seedlings, that were planted in autumn or early in winter, having been upheaved by the frost, should be pressed down and made fast before the sun gets powerful. In dry ground and warm situations Acorns should be sown, if not done in the autumn; also other nuts, kernels, stones, berries, and seeds of the hardiest kinds. You may still plant cuttings of some free-growing kinds that can be increased by this method: but it would have been better to have had this done in autumn.—*W. B.*

VII.—COTTAGERS' GARDENS.

Pelargoniums that are growing rapidly may now be repotted; the tops of the young shoots should be pinched off, to induce them to throw out laterals, so as to render them dwarf and bushy. Old pots of Musk may also be knocked out, and repotted in fresh soil, using rich, rather stiff loam for the purpose; a few of the old roots that will be found on the outside of the old ball should be placed regularly over the surface of the pot, and covered about half-an-inch deep, leaving room for water, which must be given freely when the plants begin to grow. If a few forward patches of Crocuses, Van Thol Tulips, or Anemones, in the border, are taken up about this time and carefully potted, without much disturbing the roots, they will flower beautifully, and make the window gay with showy blossoms. Hyacinths in glasses will now be showing flower, and must be carefully attended to during this changeable weather. Instead of growing them in glasses from the beginning, I would prefer raising them in pots in the usual way until the flowers begin to show colour, when the bulb may be gently shaken from the soil; the roots, being washed in lukewarm water, may be placed in glasses filled with water of the same temperature. By this method I have seen them flower as strong and well as if they had never been moved, and it prevents the flowers from being drawn, the bulbs from rotting, or the roots decaying, as often happens when they are grown in water from the commencement.

Vegetables.—As soon as the weather is favourable, a small sowing of Peas and Beans may be made; and as the busy season is at hand, everything that can now be done should be got forward against that time. Ground intended for Onions and Carrots may be pointed over, and well-broken; alterations and improvements (if any) around the cottage should be proceeded with.

Fruit.—If any fruit-trees remain to be pruned, they should be finished now; the Grape Vine *especially*, if not cut in autumn, must be delayed.

Flowers.—When the weather will permit, sowings of various kinds may be planted, such as Box, Thrift, Daisies, London Pride, or Gentianella. But while it continues cold, care must be taken of anything liable to be injured by frost.—*M. H.*

State of the Weather near London for the week ending Feb. 22, 1844, as observed at the Horticultural Garden, Chiswick.

Notices to Correspondents.

MR. PAXTON'S COTTAGER'S CALENDAR.—At the earnest solicitation of many of our Subscribers, we have determined on again reprinting Mr. Paxton's "Cottager's Calendar," in the form of a small volume, for general distribution, price 3*d.* each copy. It may be ordered of all booksellers. Gentlemen wishing to *distribute copies* among their cottage tenantry, may have them *delivered in any part of London*, by remitting a post-office order to this office, at the rate of 25*s.* for every 25 copies.

COMMUNICATIONS from the following CORRESPONDENTS are in type, and are only waiting till room can be found for them:—*J. L. Snow, A Subscriber, W. B. Booth, O., Vitis, J. Wighton, A Practical Man, Peter Mackenzie, G. Thompson, W. Billington, M. G., J. B. K. L., R. Errington, Gr., J. M'L., M. J. Berkeley.*

OUR CORRESPONDENTS will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

A CORRESPONDENT apologises for asking his questions in so brief a form as to approach a tone of impudence, and says that it is only in order to save us the trouble of reading what is needless. We can assure him that we are much obliged to him, and heartily pray that others would follow his example.

BOOKS.—*H.C.M.*—The article Botany, published by the Society for the Diffusion of Useful Knowledge, will not cost more than the sum you name.——*Amateur.*—Lindley's Theory of Horticulture.——*Subscriber.*—Loudon's Suburban Horticulturist.——*Ophilus.*—Rogers' Vegetable Cultivator is a useful book. Loudon's Suburban Horticulturist furnishes a full account of vegetables and their cultivation.‡——[=]—Rogers' Vegetable Cultivator and Loudon's Suburban Gardener.‡

CAPE HEATHS.—*W. I.*—All Ericas are pretty; the following are good, and may be easily procured; viz. Hartnelli, pink; Aristata major, red; Acuminata longiflora, purple; Tenuiflora, white, with pink shade; Inflata, white; Archeriana, scarlet; Depressa, yellow; Elegans, light-purple; Cavendishii, yellow; Mutabilis, light purple; Retorta major, pink; Lamberti rosea, flesh coloured; Hyemalis, purple, tipped with white; Tricolor, red; Linnæoides superba, purple, with white tip, and all the varieties of Ventricosa. ‡

CATERPILLARS.—*Carmel.*—The most effectual mode of preventing the ravages of the large caterpillar which attacks Apple-trees is to cut off those twigs on which the eggs can be seen in winter in broad rings. Such as escape observation at this period may be detected when the brood is hatched, and before the insects begin to scatter over the tree. Whilst in groups, and when so high as to be difficult to reach, some find it best actually to shoot them, charging with gunpowder only. But if your pest is the small green caterpillar, which rolls itself up in the leaves, picking would be an endless task. Syringing with ammoniacal liquor diluted with ten parts of water will be proper to apply occasionally with an engine or a syringe. It will do the trees good, besides being repulsive to insects, to many kinds of which, in certain stages of their existence, it will certainly prove destructive. ‖

CLIMBERS.—*W. J.*—We recommend you to plant the following against your wall: Wistaria sinensis, Clematis azurea grandiflora, C. Sieboldii, and C. Viticella; Jasminum revolutum, Magnolia grandiflora and conspicua; Bignonia radicans, and Caprifolium gratum. We cannot name seeds, and we never give prices, which is the business of advertisers.‡

CONVOLVULUS TRICHOCHUDA.—*F. D.*—This is an open Cabbage which has been introduced many years ago into English gardens from Portugal, and which has been found to be an excellent vegetable. It has a short stem and close leaves, with very thick ribs. It is not hardy; its seeds may be sown with advantage in March, or if sown in August, the plants should be transplanted into a frame in September and treated during the winter like Cauliflower plants. ‡

CRICKET-GROUND.—*A Cricketer.*—Fill up the cracks in your ground with fine soil well mixed with one-sixth of guano; and a week after rain has fallen on it, sow Crested Dogstail and Sheeps' Fescue grasses in equal quantities. If the grass is in bad order, a topdressing of soil as aforesaid will do it much good. Do not use hay-seeds, because they bring weeds.

CUCUMBERS.—*A. Z.*—A description of Mr. Mills' Cucumber-pit is given in his treatise on the Cucumber, &c., and we have no right to publish it. Two good Cucumbers for a frame are the Southgate and Syon House; the former is excellent for early use. Two others may be Mills' Frame and Allen's Victory of Suffolk.‡——*Ophilus.*—The Early Frame or the Early Southgate are suitable kinds to begin operations for a frame with. An account of Convolvulus Trichochuda is given above. ‡

DOMESTIC YEAST.—*J. D.*—We gave the receipt at p. 70, on the authority of the correspondent at Hillsborough. We, however, like you, cannot discover that the preparation has any of the properties of yeast. A ready means of making yeast would be extremely useful.

FRUIT-TREES.—*Ellesmere.*—In order to prevent your Fruit trees from running so much to wood, you may, as you propose, root-prune them by cutting a trench 18 inches wide, about four and a half or five feet from the wall, down to the gravel, which is nearly two feet deep from the surface of the ground, smoothing the mutilated ends of the roots with a sharp knife. This trench may be then filled up again with fresh soil from an old dry pasture. This operation will check the over-luxuriance of the trees, and tend to the formation of flower-buds. The ground should never be dug within at least four feet of the stem; but the surface of the soil should be frequently broken with a fork, and, therefore, your plan of spreading gravel four inches deep along the surface of the border will not answer. The distance of four feet from the wall is too small a space to confine the roots of fruit-trees of any size in; they should at least have six feet of a border.‡——*Carmel.*—Root-pruning need not be repeated during three years at least. Autumn is the best time to perform the operation. Guano may be applied to fruit-trees at the rate of 4 cwt. per acre; and best in a liquid state, early in spring. ‖

FUCHSIAS.—*A Subscriber, Milton,*—Epp's Scottish Bride and Bridegroom, Standish's Colossus and Attractor, Miller's Constellation, Smith's Queen Victoria, robusta, reflexa, splendens, Paragon, Formosa elegans, Conspicua arborea, and Venus victrix. Turfy peat, loam with a little leaf-mould and a small quantity of silver sand is the proper compost for Fuchsias. We have not heard of charcoal being tried, but we have no doubt of its agreeing with this tribe.*

HEATING.—*A Novice.*—A stove is useless for the purpose you describe. It will be much better to build a flue at once; but nothing will really answer your purpose as a substitute for stable-litter, except hot-water gutters. An Arnott stove will be expensive, and will not be of service in your case.——*Horndean.*—There is no object in "bringing steam" nearer its work." Once admitted into the atmosphere of the Vinery, it will diffuse itself abundantly, if there is a sufficient supply, as seems to be the case, in your apparatus; 6-inch pipes are substantially large to attain it by. ‖ Make the gutters of inches deep and place 4 inches of cross-timbers upon them, in which plunge your propagating-pots.——*R. J. N.*—The Apes, buried in sand and filled in at the sides, will give the most steady bottom durable heat to sawdust, which, however, is a very bad material, and far inferior to common cinders, but it will probably prove too dry. From 70° to 80° is the best temperature of the plunging material in a hot-bed; but it is needlessly high for Roses, which will not bear 80° for any length without running into weak wood; for them 60° is sufficient, and such air-heat as we find on an average in a warm dry spring day. Roses are ruined by excessive stimulus, where forced. ‡ ‖

HEDGES.—*Mainyfield.*—Of your young hedge there should not be more of the young wood cut the first season than what is supposed the frost would destroy during winter. The same method should be followed the second year also, excepting perhaps some of the strongest shoots, which may be lopped to the level of the others. By the time the hedge is three years old, it may be dressed on the sides, so as to make it straight, but nothing more should be taken off the top shoots until it has arrived at the permanent height. You may cut your Beech-hedge now; the height may be about 3½ feet.‡

INSECTS.—*J. F. B.*—We are unable to advise you regarding the Peach-trees, as it is impossible to ascertain from your communication what insect it is that does the mischief; but if you will transmit us specimens with the buds or leaves, as soon as the trees are attacked, we may be able to suggest a remedy. *R.*

LILIES.—*J. M.*—The real Lilium lancifolium is not known to be in Europe; of L. speciosum there are several varieties, one of which is called Eximium. The L. lancifolium of gardens is the same as L. speciosum. You had better write to *Mr. Towers*; we cannot find room for your observations.

MANURES.—*A Beginner.*—Sulphate of ammonia is employed as a topdressing for grass land in March, at the rate of 2 or 3 cwt. per acre.——*J. P.*—We never saw woollen rags used for Potatoes, but presume they are chopped into pieces about an inch square.——*Ophilus.*—We should try Potter's guano for both garden and meadow.——*A Subscriber.*—Soot is a good material in its way, but either superphosphate of lime or Potter's guano, or Peruvian guano, are a thousand times better.——*Tyro.*—Either Potter's or Peruvian guano will answer your purpose. Use them dissolved in water.——*Winton.*—Give a wine-glassful of superphosphate of lime to each pot in which your Pelargoniums are to flower. Apply it as a topdressing only.

MEALY BUG.—*A Subscriber.*—In order to destroy this, when the leaves are fallen, carefully rub off from your Vines all the rough exterior bark, using a stiff brush where required to get into the angles of the branches. Then wash the Vine with strong soap-suds; or if you do not mind appearances, you may cover them with whitewash, which will do as well. This operation will remove the greater part, if not the whole of the insects which may remain on your Vines.‡

MELONS.—A correspondent inquires which is the best Melon for preserving? Will any of our readers oblige us with an answer? ‡

NAMES OF FRUITS.—*C. H. C.*—No. 1, Catillac; 221, Bergamotte de Hollande; 155, Gilogil; 224, Virgouleuse; 276, Echasserie.‡

NAMES OF PLANTS.—*Tropical.*—4. Hedysarum mutans. 7 and 8. Species of Eugenia. 9. Some Convolvulaceous plant. We regret our inability to give you further information; but it is impossible to name tropical, or indeed most plants, when only in leaf, without an amount of inquiry which we are sure you would not wish us to undertake.

ONIONS.—*A Subscriber.*—Guano is an excellent manure for Onions. To your bed 20 yards long and 4 feet wide, you may apply 25 lbs., being about at the rate of 4 cwt. to an acre, which is quite sufficient for garden purposes. It being of a hot burning nature, must be well mixed with six or seven times its bulk of good light soil. The Onions may be sown in drills about nine or ten inches apart, drawn lengthwise in the bed. In this way they are more easily kept clean than when they are sown broadcast.‡——*Mairyfield.*—Presuming that your ground has been rough dug in autumn, and duly exposed to the action of the weather when it is sufficiently dry, you may point over the surface slightly with a spade, breaking it small as you proceed. Sow in drills, as directed above, on the first fine day after the beginning of March, if the ground is in a fit state for the reception of the seed. ‡

PELARGONIUMS.—*A Beginner.*—These may be shifted now with advantage. A mixture of two parts turfy loam to one of well-decomposed cow-manure, not less than three years old, with a small portion of silver sand, will be found a suitable compost for blooming them in.‡

PRUNING.—*Semuralicus.* — Prune Common Laurels, and all those which are rather tender, just when the buds are swelling in spring. Such as are quite hardy may be pruned at any time during winter.

RASPBERRY.—*T. P.*—We are unable to find anywhere an analysis of the ashes of this plant.

SALT OF THE EARTH.—I beg to inform "N. H. Gritton" that the words, "Salt of the Earth" were quoted from a sermon, an old sermon, but a famous sermon—the Sermon on the Mount. *P. M.*

THE OLIVE.—*F. W. C.*—See p. 84, 1843. It is absurd to suppose that a tree can improve the soil in which it grows. The efflorescence seems to be nitrate of lime.

VINES.—*R. W.*—The check which takes place at the extremities of your Vine shoots after the latter have grown from 6 to 12 feet in length, is probably occasioned by a want of sufficient moisture at the roots. ‖——*A Subscriber.*—Having commenced forcing your Vines at the temperature of 50°, increase to 60°, and when the leaves expand, 65° to 70°; when setting, 75° to 80° will not be too much. ‖

MISCELLANEOUS.—*A. B.*—There is but one variety of Camellia reticulata. But that is apt to have white leaves without getting out of health. Warmth prevents it. *C.*—Loudon is right. But Deodars do not require a moist subsoil. Cedars will succeed better in a soil less dry, even with a subsoil of clayey loam. The Araucaria imbricata seems to like light land. We doubt if it will succeed in clay or damp places. The tops and sides of hills are its favourite haunts. It is an ugly tree when old. You will find your question about other Firs answered in former papers on Coniferæ in this Journal. P. Pallasiana is the same as P. Taurica. We doubt whether you can get any except grafted plants of P. Sabiniana and Coulteri. We cannot answer the question about Plane mills, and never give prices. *An Amateur Florist.*—We never recommend nurserymen.‡ *A Young Gardener* will find excellent information on the night temperature of Vineries given at p. 459, 1842. Pine.—No evergreen grows faster than Furze or Broom; or, if you want a tree, than the Common Laurel. The Huntingdon Elm is one of the fastest growers, but the Cæruleon Willow beats it, and so does Sir Charles Wager's Maple. Acer macrophyllum is quite hardy; it grows about as fast as the latter. The fastest growing Pine is the Laricio.——*Tyro.*—The black Spanish Onion. Use for them charcoal and superphosphate of lime.——*Z.*—We do not understand your objection. We use less small type than ever. Any *fine* sand that is free from iron or salt will do; coarse sand is thought not to answer the purpose. We believe common coke, which contains much sulphur, is injurious to copper boilers.——[=]—A span-roofed house or pit running north and south is suitable for a propagating-house. ‡——*Alpha.*—Aponogeton distachyon is, or was, naturalised in the water in the Botanic Garden, Edinburgh, but we have not seen it here in the south.——*A Subscriber.*—No. 1 is out of print; it may be had by applying at the publishing-office. *J. W. J.*—Answered p. 104.‖——*Mr. Pearson.*—The Pine Fern ceased about five years back.

*** As usual, many communications have been crowded out this week.

BALSAMS.—In *Mr. Cameron's* advertisement last week, for *Standard and Dwarf Pansies* read *Standard and Dwarf Roses.*

EXAMPLE FARM.

WANTED, to Rent on Lease, for a term of not less than 21 Years, to enter on, Lady-day, a Commodious Dwelling-house, and about 100 acres of Arable Land, for the purpose of forming it into an EXAMPLE FARM. It must be near to a Railway station, and within 50 miles of London; on the Greensand formation, under the chalk, or on the London clay or Plastic clay above the chalk.—Apply to Mr. Mowton, Chesterhill, Morpeth.

AGRICULTURE.—A Gentleman occupying a Farm of 300 acres, of various descriptions of soil, pleasantly situated in the highly cultivated county of Norfolk, and within five miles distance of three of its thriving Towns, is desirous of taking one or two YOUNG MEN, to learn the practice of Agriculture. The parties would in all respects be treated as members of the family, and would have the opportunity of regularly attending Norwich market (decidedly the largest and most celebrated provincial stock market in England,) and also the advantage of becoming acquainted with the most approved specimens of Agricultural Implements and Machinery. References given and required. Address, J. B., Post Office, Norwich.

The Agricultural Gazette.

SATURDAY, FEBRUARY 24, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, Feb. 28 . Agricultural Society of England.
Thursday, Feb. 29 . Agric. Imp. Society of Ireland.
Wednesday, Mar. 6 . Agricultural Society of England. Highland and Agric. Society.
Thursday, Mar. 7 . Agric. Imp. Society of Ireland.

FARMERS' CLUBS.

		Feb. 29	Richmondshire.
March 1	Hadleigh. Wrentham. Debenham.	March 5	Cullompton. Cardiff Gloster.
March 4	W. Market. Yeaford. Wenlock. West Hereford.	March 5	Framlingham. Rayleigh. Collingham.
		March 6	Harleston.

THE present is THE PROPER SEASON FOR PLANTING BEANS. There are many ways of cultivating this plant. The seed is by some sown broadcast; by others it is hoed in or drilled, and by many it is dibbled. During the growth of the plant the land is in some districts flat-hoed merely; in others, it is horse-hoed and cultivated as when carrying a fallow-crop, and in many instances it is neglected altogether; and this variety of management is equally conspicuous in the treatment of the crop at harvest. We have seen Beans, sown broadcast upon land which had just been ploughed, present on coming up all the appearance of having been drilled; and in this case, the furrows being about 10 inches wide, the advantages in the cleaning of the land, which are afforded by narrow drilling, were cheaply obtained. The regular distribution, however, of the seed, with all the advantages following from it to the crop and to the land, which are obtained by drilling, hoeing, and dibbling, render these plans in every case preferable to that of sowing Beans broadcast.

The first of these methods is the cheapest. Beans are drilled in at all distances from 10 to 26 inches. In the former case, the land can only be cleaned by hand-hoeing—in the latter, it can be cultivated in every respect as during a fallow-crop; and in cases where the Bean-crop is made preparatory for that of Wheat, this is an especial advantage. In the latter case, which is general in Scotland, the land is manured in drills 27 inches wide, the seed having been previously sown in them by a hand-barrow used for the purpose; the ridges are then split by the double mould-board plough, the seed and the dung being thus covered together. Before the plants are up, the land is harrowed, the ridges formed by the double mould-board plough being thus in a measure obliterated. The plants, when up, are pared, *i. e.* a small plough is sent down each side of the row, throwing the earth from it into the intervals between the rows. These intervals are horse-hoed and hand-hoed, and after a while the double mould-board plough is again put in requisition—the plants are earthed up and left till harvest time. In drilling Beans, four or five bushels are sown per acre. In some districts Beans are drilled by the Bean-barrow in a simpler manner than that just described, this implement being sent down every third furrow as the ploughs are at work in the field. The furrow slices being 10 inches wide, it is evident the plants will come up in rows 30 inches wide.

The operation of hoeing in Beans costs about 6*s.*, and requires four bushels of seed, per acre. The seed is planted across the ridges in rows, about nine inches apart; the labourer, in the act of making each trench with his hoe fills the one already made, in which he has scattered a quantity of seed. Beans are dibbled in two ways; in the one, the unharrowed furrow slice is the labourer's guide, and two or three seeds are put into each of the holes, which are made about 10 inches asunder in the alternate furrows; in the other, the land is harrowed down, and two lines are employed as a guide for the labourer. These lines are placed about 18 inches apart, generally across the ridges, and the labourer facing them, manages both at once. He makes in succession four holes about 10 inches asunder, in the near row, putting about a couple of Beans into each as it is made, and after doing the same in the far row, he moves sidewards up the line, and repeats the operation. The holes are filled in by a subsequent harrowing. Two, or at the most, three bushels of seed are thus planted, and about 5*s.* an acre are paid for the work. Formerly, the operation used frequently to be paid for by the bushel sown, the sum being 20*d.* or so, but this unreasonable method of payment is being dropped now—it acted as a premium upon carelessness and dishonesty.

The Bean prefers land such as that affected by Wheat—a stiff loam suits it well. Many kinds of Bean are sown, but they are all, botanically speaking, varieties of one species. The Mazagan, long-podded, and Heligoland, are among the rarer kinds cultivated in fields; the most common being the Horse and the Tick Bean, of which the latter is the more prolific and superior in quality, and the former the more hardy.*

THE following are remarks upon the subject of SPADE-HUSBANDRY, by the late Rev. W. L. Rham, who contributed so many valuable articles on Agricultural subjects to the *Gardeners' Chronicle*. We insert them here, because, without determining whether or not in some cases *the farmer* can profitably cultivate land wholly by manual labour, there cannot be a doubt that he would be greatly benefited by a more frequent use of the spade, not as a substitute for the plough, but as an assistant to it; and the following remarks are well calculated to recommend such an employment of manual labour:—

At times such as that which, we hope, has now passed, when there is a stagnation in trade, and when men able and willing to work cannot find sufficient employment to maintain themselves and their families, there is an outcry raised against all those contrivances by which manual labour is diminished. Spade-husbandry is naturally looked to as a palliative, if not a remedy; and many calculations are made to prove, that by substituting the spade for the plough, the produce of the land will be so much increased, as fully to repay the expense of the additional labour. There is no denying the truth of many of these calculations, and if we have any doubts, we need only some fine day take the steamer to Antwerp, go down the Scheldt to Tanisse, or any village in the Waes country, and judge with our eyes of the success of Spade-husbandry. We may return within the week perfectly convinced, however incredulous we were before. The Spade-husbandry there enables an active industrious man to cultivate from six to ten acres of light land; to pay a high rent for it; to maintain his family comfortably, and often to lay by a sum of money to set up a son with, or give a portion to a daughter, if not to buy a piece of land for his own occupation and that of his children after him.

This is a pleasing picture and a true one; why not, then, introduce it in England? To a certain extent it might answer; a hard-working, sober, industrious family, where every individual from the old grandmother to the child, just out of its infancy, contributes something in the shape of labour to the common stock—where they are content to live on coarse bread and skim-milk, or butter-milk soup, where the men are at work before the sun is risen, and after the evening twilight; such a family might live on the produce of a few acres of land, and be happy and contented; but would this suit the English labourer? Ten hours' work is a long day for him; he is accustomed to have some bacon at least with his white bread, and a pint of ale is no extravagance after the day's work is over. His wife has her children to nurse and attend to. His boys and girls go to school to fit them for something better than mere daily labour. In short, he lives like a gentleman when compared to the foreign labourer. Do we regret this, or find fault? Certainly not. Would that every labourer could always command these comforts, besides that of a clean neat cottage and well-kept garden! Spade-husbandry—that is, digging the land instead of ploughing it—will not afford this; but it may be accomplished by the union of machines to abridge labour, and the application of a better system of tillage, in which much more manual labour is employed. Instead of wearing out the strength of a man by making him turn up a hard and compact soil, why not do this by the brute force of horses or oxen while the man is set to work where his dexterity and ingenuity may be exercised, and where he can do what neither horses nor implements can do so well. We do not allude to draining, however useful and profitable an operation on all stiff cold soils; for, in time, it is to be hoped all wet soils will have been laid dry, and little labour will be required to keep the old drains in order; but when the land has been ploughed once, or oftener, is it already in the best state for cherishing the seed and nursing the young plant? If it has been richly manured, is it so free from all useless weeds that the crop will suffer no diminution from their presence? Or is it imagined that in the large fields of the farmer there is no use for constant manual labour when it has been ploughed, cross-ploughed, subsoil-ploughed, scarified, rolled, and harrowed, and after the seed has been sown or drilled regularly? If so, we will invite the most experienced farmer to walk over his own fields, to see the state of the surface, to examine the depth at which one seed has been harrowed in, while another is scarcely covered with earth, so that the first bird which passes by readily discovers and preys upon it. We will take him along the furrows which separate the lands, or stitches, as they are called. If the soil is heavy, how many clods are lying there which will impede the course of the waters in heavy rains; if it is loose, how many places are there where the soil has slipped more or less, leaving some *of* the seed bare which it should have covered! How much attention and light labour might be applied here, which would suit women and children, without fatiguing them!

There is the operation of dibbling the seed in one season, of hoeing the crops in another, of forking-up land which has been ploughed, to break the clods, to let out the small seeds imprisoned in them, to destroy those which have just sprung up; in short, to make a field resemble a garden. If it be objected, that the crops will never repay the outlay, we maintain the contrary. If it has been clearly shown by experience that even the slow and laborious process of digging the ground is fully repaid by the crops, is it not reasonable to expect the same result from a more perfect tillage, attended with less hard labour? There are many examples of crops of more than double the usual average on land treated in every respect as is usual in a farm, except in the greater attention to minutiæ, which are overlooked in a field, but carefully attended to in a garden. Why should not the surface of a field be gently raked when it begins to set after rain, that is, form a crust, so as to impede the growth of the young plant as it rises to the day? Why should the intervals of the stitches not be dug out, like those between seed-beds in a garden, and the earth thrown over the plants to strengthen them by the addition of fresh earth, while the deep intervals collect all the superfluous water, which might chill the roots, if not rot their fibres. Let the common field-seeds be sown carefully in a garden well covered and pressed, or trodden—the surface raked smooth, the paths between the beds kept neatly shovelled out, and who will not expect an extraordinary crop? It is well known that injudicious manuring diminishes the crop, but with improved tillage the crop is always more certain and abundant. The finest and richest soil badly tilled will produce but a moderate crop, while a naturally bad soil may be so improved by judicious tillage as to produce far more abundant crops than the richer. All that is required is a good system; we would not have men harnessed to carts, where brute strength alone is required, to draw a load; but we would set them to such work as requires judgment and dexterity. To what extent this may be applied to the operations of husbandry, experiment and observation alone can teach; but that it may be so, there is every rational probability.

That we may not be supposed to suggest impracticable improvements, let us only consider how many crops are lost, or greatly diminished, in consequence of some circumstances which affected the first shoots, and caused a retarded and consequently weakened growth. How many plants of Wheat are thrown out of the ground on light soils by the frost, which, if the seed had been deposited at a proper depth and firmly trod in, would have produced numerous stems and ears? The attention of a man directed to the state of a field might avert innumerable evils; the first appearance of blight or mildew might be watched, and correctives applied, which strict attention to the appearances would soon discover; the ravages of worms and insects might likewise be arrested as soon as discovered, and a crop, now left to take its chance, might be defended from its enemies and secured from harm. What good gardeners do with respect to fruits and vegetables, by care and attention might be readily extended to the produce of the field, and, doubtless, with the same success. A man with a spade, a hoe, and a rake, cannot fail to find ample and useful occupation in a field at all seasons; and if he is interested in the result, by a premium on any increase of crop beyond the usual average, he will well earn the wages he may receive.

Much useful labour might likewise be applied to increase the produce of the dairy. The stalling of cows at all times of the year is found decidedly more economical than the old practice of letting them roam at liberty in large pastures. Natural and artificial meadows may be cut before the flower of the Grasses expands, and afford excellent and abundant food for the cows; while women and children may be employed in eradicating all plants which are either useless as nourishment, or hurtful to the cows by giving a taste to the milk.

All these are mere suggestions worthy of a trial; but they are not vague and crude fancies, for most of them have some foundation in experience and observation. The principle we contend for is simply this: that, without adding to the more laborious part of the work, many more hands might be employed on a farm, so as amply to repay the cost, by trying to imitate the neatness and perfection of garden cultivation

* See Professor Low's "Elements of Practical Agriculture."

on a larger scale. Much may be learned by watching the cultivation of allotments of land, where these are judiciously let to industrious labourers; after their day's work you may see them carefully examining their little plots of Wheat, or any other produce, with a spud or little hoe—the weeds are picked out before they are well out of the ground—a clod on the surface, if sufficiently dry, is broken by a slight blow with the back of the hoe—a plant which appears rather loosely set in the ground is made firm by a tread of the foot; all this is very slight work, yet at harvest we see crops of seven and eight quarters of Wheat per acre on land which, in the memory of man, never produced half that quantity, and which is by no means abundantly manured. Suppose that a week's work of an able-bodied man in a Wheat-field only ensures an increase of two bushels at harvest, the extra labour and attention will be paid for; but every one knows that the increase of two bushels on every acre will be considered as no great thing in a field of ten acres thus attended to; yet this increase will repay a constant unremitted attention of a man for ten weeks, giving him ample wages.

But what is the farmer the better for this? Much, in every way: his crop has been kept free from weeds; the labour for the subsequent crop is much lighter, and his land is improved in texture by all this careful tillage. If he was in the habit of fallowing his fields to clean them, he may defer this process for a longer time, if not omit it altogether. If he sows Clover or artificial Grasses, the carefully prepared surface insures their growth and saves much seed. The failure of a sowing of Clover is no trifling loss, as we all know, and an improved tillage will decidedly diminish the chances of failure. In short, where there is the wish to do good, while we benefit ourselves, and have the pecuniary means to meet some additional expense, nothing can be more strongly recommended than to apply constant and minute manual labour to the improvement of the soil, and thus to promote the certainty and beauty of the crops.

EXPERIMENTS WITH NITRATE OF SODA, &c.

(*Continued from page 106.*)

I APPLIED the three dressings as above stated, viz., 1 cwt. of nitrate of soda per acre, manganese and nitrate of soda in equal quantities, 1¼ cwt. per acre, and Guano mixed with soil, to rows of Turnips after they had received the second hoeing and begun to spread over the top of the drill. The effect as to the colour and growth of the tops was the same, and in the same proportions as on the Clover-fogg; but the final result of this experiment remains to be proved by the weight of the roots, when taken up, as compared with each other and with rows that had no top-dressing.* I applied the same dressings to Rape, sown upon bone manure, when it was about three inches high, and in this case the nitrate and mixture produced the most decided effect that I had yet seen. Within a month those rows had grown to twice the height of the rest of the field, and were covered closely over the intervals, bearing fully double the weight of produce, although about a week after being applied the leaves were spotted and blistered, probably owing to the nitrate not having been pounded sufficiently small. Those done with guano were better than the part which had nothing, but much inferior to that to which nitrate had been applied. Some sheep were put upon that part of the field on the 24th of August, and in a week had eaten the rows done with nitrate and manganese close to the ground, while those done with guano and left undone were hardly touched, a decided proof that the application of nitrate to such plants has the effect of not only increasing the quantity to a great extent, but of rendering it more palatable to animals, and I doubt not in an equal degree more nutritious. I found nitrate very beneficial to the growth of Tares, and extremely so to six acres of the second year's grass to which I applied it at the rate of 1 cwt. per acre. The effect was greater and more rapid than upon the first year's Clover; probably because being a thicker cover, the whole of the nitrate would be retained by the blades of grass; whereas in the other case, a part would fall upon the ground. This land being in pasture the increased produce could not be brought to the test of actual weight, as in hay, but the stock having been kept off it for a week after sowing the nitrate, it acquired such a growth as, in comparison with other land, to keep nearly double the quantity of sheep, or, at any rate, I am confident at the rate of five per acre instead of three. My experiments upon Corn both last year and this have been unsuccessful. The nitrate stimulated a great growth of straw. In both years a great deal of rain fell just previous to the harvest, in consequence of which those portions have been laid and much injured, producing a great bulk of coarse straw, but little grain. And even in cases where both Barley and Oats seemed in no danger of being too bulky and were not lodged, a second growth was produced, and they are now being cut full of green and immature shoots, while the good grain does not appear to be more in quantity nor so good in quality as that which had no nitrate. A rapid growth of straw with a heavy blade, just before shooting out the ear, is always attended with much risk, and as nitrate produces that effect, if applied to Corn after it has grown 12 or 15 inches from the ground, it must always be attended more or less with danger. And when applied very early, and before the plants cover the ground, it produced, in my case, no effect at all.

With respect to guano, I am sensible that the result of these experiments forms no test of its value as a manure. Being the produce, accumulated for ages on the rocky islands of the Pacific, of sea-fowl, which feed on fish, it contains a large proportion of organic matter of the richest and most stimulating kind, and ought to be applied mixed with ashes, charcoal, or some other substance, as other manures are, to the soil, so as to be accessible by the roots of the plants. I could not, however, procure any at a proper season for using it in that way, and therefore determined to try it as a top-dressing in the same way as the others.

The numerous experiments which I have made with nitrate of soda lead me to the determination in my own practice, to use it as much as possible on grass and green crops, and only on Corn in such situations as run no risk, be the weather what it may, of the crop being lodged from too great a growth of straw. I have satisfied myself that I can obtain the requisite quantity of hay upon two-thirds, or rather less, of the land which I have hitherto assigned to it by the application of nitrate of soda to the grass; so that I have one-third of the land at liberty to feed sheep. I am also satisfied that its application to pasture-land increased the produce at any rate by one-third, and to Rape, in one instance at least, by one-half; the consequence of which must be an extra production, in equal proportions, of mutton and wool, and an additional return of manure from the sheep to the land, which will produce its effect upon the succeeding crops of grain, not by stimulating a rapid growth at any peculiar stage, as nitrate does, but by entering gradually and regularly into the whole process from the germination of the seed onwards to the maturity of the crop.—*John Grey, Dilston House.*

* Dec. 9th, 1851.—The Turnips were pulled this day and carefully cleared of tops and tap-roots, after which they were carefully weighed, under the inspection of Mr. Hunt, and the following Table shows the result:

Top dressings.	Square yards in each Portion.	Weight of Turnips in each Portion.	Weight per acre.
		st. lbs.	tons lbs.
Nitrate of soda	166 4 9ths	117 8	21 58
Manganese & nitrate	166 4 9ths	117 0	21 58
Guano	166 4 9ths	127 6	23 25
Nothing	166 4 9ths	198 10	22 165

The tops were not weighed, as their value is small, and would go a short way in altering the comparative value of the produce; but the drills to which the nitrate, and mixture of nitrate and manganese were applied, showed much more top throughout the season than the others, although in the end the roots weighed less. Whether these roots would have gone on to increase till they had overtaken the others, if they had not been checked by the unusually severe frosts which came on early in November, I do not pretend to say; but the experiment tends to confirm me in the opinion already expressed, that saline manures are more easily and efficaciously applied to green crops, such as Grass, Vetches, and Rape, than to grain or the bulbous-rooted plants. On the contrary, the effect produced by the Guano is very encouraging, especially when it is considered that I did not receive it in time to apply it in the rows, as bone-dust and other manures are applied, and that comparatively but small particles of it could have found access to the plants when scattered along the tops of the drills after the Turnips were first hoed.

N.B.—The Turnips referred to above were all grown upon an ordinary dressing of farm-yard dung.

REPORT OF DR. VON MARTIUS ON GUANO.

(*Continued from page 106.*)

THE first chemical analysis of guano was made by Fourcroy and Vauquelin, from the specimen brought home by Baron von Humboldt. These chemists found that it consisted of at least a fourth part of uric acid, which was in combination with ammonia. They also found oxalic acid in combination with ammonia and potassa, the phosphates of ammonia, of lime, and of potassa and ammonia, and a small quantity of a fatty matter. Soon after this analysis, Klaproth made his known; and then Völkel and Vertels published a very accurate quantitative analysis. It may not be uninteresting to give the results of these analyses.

	Klaproth.	Völkel.	Vertels.
Urate of Ammonia	16	9	3.244
Oxalate of Ammonia	—	10.6	13.351
Oxalate of Lime	12.75	7.	16.360
Phosphate of Ammonia	—	6.	6.450
Phosphate of Ammonia and Magnesia	—	2.6	4.136
Sulphate of Potash	—	5.	4.227
Sulphate of Soda	—	3.8	1.119
Muriate of Ammonia	—	4.2	6 5
Phosphate of Lime	10	14.3	9.940
Phosphate of Soda	—	—	5.231
Muriate of Soda	0.5	—	0.1
Alumina	—	—	0.104
Clay and Sand	22	4.7	—
A waxy resinous substance	—	—	0.6

These analyses show considerable difference, but this may be explained by the varying age, purity, and origin of the guano. It thus appears that amongst animal manures guano clearly claims the first position. It is uncommonly rich in ammoniacal salts, and these salts act very favourably on vegetation. They abstract from the air its carbonic acid, and it is through its means that those various proximate principles are formed, such as starch, mucus, resin, lignin, &c., which constitute the body of the plant. With the exception of the oxalate and the phosphate of lime, nearly all the salts are soluble in water. The urate of ammonia is not so, but then in the atmosphere it undergoes a decomposition, by which carbonate of ammonia is formed, which is equally soluble with the rest of the salts, and is taken up by plants, and contributes very much to their nutrition.

The ease with which these salts are decomposed by the air, and rendered partly volatile, will account for the fact that plants manured with Guano generally present early in the morning, accumulations of dew on the points of their leaves. The Guano absorbs the surrounding air, and also the vapour of water that may be in it, which is especially serviceable to plants, and this is why Guano is so valuable a manure in dry, barren regions.

If we compare Guano with other excrementitious manures, we shall find it far preferable to those afforded by man or the other mammalia, which do not generally contain more than 20 per cent. of matter that can be appropriated by plants as food. It is thus five times better than night-soil, and it is also very superior to the so-called *Poudrette*, which, in the drying, loses, through putrefaction and evaporation, the greater proportion of its ammoniacal elements.

In birds, the excretion both of the kidneys and intestines are contained in the cloaca, and thus it is that the volatile elements of the one get combined with the firmer elements of the other. The Guano is also the better, from the circumstance of its being produced by sea-birds, which live entirely on fish, and eat no vegetable matter. The exposure also of the Guano to the heat of a tropical sun, as soon as deposited, prevents the volatile elements from flying off, by the formation of a hard crust upon its surface. The manure of our dove-cotes suffers a considerable loss by its exposure to the air.

In its action on vegetation, and in its chemical composition, Guano may be compared to the manure of dove-cotes. Davy found in fresh dove-cote manure, twenty-three parts soluble in water, consisting of uric acid, urate of carbonate of ammonia and common salt; but in the dried manure only eight parts in the 100 soluble. Sprengel analysed this manure, six months old, and found 16 per cent. of soluble matter; there was very little uric acid, and a great deal of carbonate, sulphate, and urinate of ammonia, with some common salt and sulphate of potash. The eighty-four parts insoluble in water, consisted of siliceous sand, phosphate of lime and magnesia, and traces of alumina, iron, and oxide of manganese.

(*To be continued.*)

MANX AGRICULTURE.—No III.

(*Continued from page 88.*)

THE spirit of emulation which prevails throughout the United Kingdom, and is extending its beneficial influence under the auspices of Agricultural Societies, has at length winged its way to the Isle of Man; and amongst the benefits which have followed in its train, must be prominently mentioned improvements in live stock, and in Agricultural implements. Owing to the peculiar situation of the island, the Manx herds of cattle are of so mixed a nature as to be almost indescribable. Specimens may be seen of the "Hereford" crossed with the remote "Guernsey," or hardy "Highland;" and of the "Holderness" or "Durham" crossed with the Polls of adjacent Galloway, or the beautiful breed of Ayrshire.

These incongruous mixtures are, however, rapidly declining, and the importation of some highly-bred short-horned bulls and heifers is producing incalculable benefit throughout the length and breadth of the island. Honourable mention must be made of the short-horned herds of Faulder of Ellerslie, Gawne of Kentraugh, Farrant of Jurby, and of the Jeffresons; nor should the pure Ayrshire dairy stock of Mrs. Miller of Ballaconyea be omitted.

The breed of sheep is also rapidly improving, and on the "bleak and barren rock" (as Mona has been ignorantly described) may be seen grazing in health, breed, and beauty, undiminished by importation here, the heavy Cotswold and New Leicester, the beautiful South-down, and the hardy Cheviot; while the active little Manx sheep still retain undisturbed possession of the heathy mountain pastures. With reference to the implements of Agriculture, there is still great need of improvement; for, although the old wooden plough is for the most part superseded by one of iron, and the useful double mould-board is in much request, there is still great lack of those newly-invented instruments, by the use of which culture has been improved, and labour diminished, in England. Much benefit would arise from the more frequent use of scarifiers, couch-rakes, and improved horse-hoes in the tillage of the land; and of drills and dibbling machines for depositing seed corn, the greater part of which are comparatively unknown. Great excuse must, however, be made in this respect, as it would be difficult for the tenant farmer, or even the small Manx freeholder, to encounter single-handed the expense of those mechanical improvements which are so accessible to British farmers. It occurs to the writer that some such plan as the following would be alike practicable and beneficial, and may perhaps be applicable to many districts in England as well as to this island.

Let some portion of the funds of the local Agricultural Societies, or of Farmers' Clubs, be appropriated to the purchase of the more expensive and useful implements. The island might be divided into districts (and the present parochial division would be very convenient), in each of which these implements might be deposited. All subscribers to the Society should have the liberty of using them, and by an amicable arrangement no great clashing of interests need occur. A small sum should be paid for their use, sufficient to repair wear and tear, and to provide new ones. Thus would an Agricultural Society prove itself of real and practical benefit to the Manx farmer.

It has been before stated that the soil of the island is very various, and the rent of land is influenced accordingly, but it will be found to range between 1*l.* and 3*l.* per statute acre. Near the principal towns that maximum is exceeded, as accommodation land is in great demand. There are, however, no other outgoings in respect of rates, taxes, &c., except that, for each cart kept on the farm, a day's labour per annum to the high-road is expected and demanded. Tithes are adjusted as in England, but are short in their form and unintelligible in their language, and

few more stringent clauses are inserted than the reasonable prohibition from selling manure, straw, or meadow-hay—from taking two white or grain crops in succession, and a stipulation on the part of the tenant to leave a proper proportion of the arable land down with grass-seeds at the end of his term.—*Cultor.*

(To be continued.)

ON MINERAL AND INORGANIC MANURES.
No. VIII.

By Professor Charles Sprengel.

Marl is one of those mineral substances which can easily be used as a manure on a large scale, for it is to be found in many localities, generally forming thick strata. The most barren localities are at times most wonderfully improved by it, and this is the more important for the Agriculturist, as it is to be obtained at a trifling expense. The extraordinary effects which the marling of fields has produced have induced some Agriculturists to consider it the *ne plus ultra* of all manures; they thought that it could even supersede dung. There have been put forth several theories as to the mode in which marl acts, but it would lead me too far to state them all, and it would take up still more time to refute them. I shall therefore limit myself to that one which is not only in accordance with the newest doctrines of Chemistry and Vegetable Physiology, but is also confirmed by the experiments which I have made on the manuring properties of the single component parts of marl. I shall leave it with the reader to compare my theory with the older ones; and I do not doubt, that if all be taken into account that I have previously said on the nutritive process of plants, he will find them to be irreconcileable with Nature.

If we leave clay out of the question, which can only improve the mechanical texture of the soil, the chief ingredient of marl, according to weight, is carbonate of lime, which at times amounts to 50 per cent., and more. We shall treat of it first. As lime has a great affinity to humic acid, marl will endeavour to form that acid (provided that it does not already exist), from the vegetable matter and the coal of humus in the soil; but as the lime is already combined with carbonic acid, this will in a great measure prevent it; and then its combination with humic acid is very gradual, and moreover, requires for the operation (what is not to be overlooked), the assistance of the sun's heat. When lime has combined with humic acid in the proportion of 13 to 87, it is soluble in 2000 parts of water, and is then suitable as food for plants. The carbonic acid, on the other hand, which the humic acid has displaced is received by the water, and is also absorbed by the plants. The advantage, however, which the plants derive thereby is not great, as will appear from the following calculation: Suppose 20,000 lbs. of marl, containing 30 per cent. carbonate of lime, were brought on one Magdeburg acre of land, the plants would receive thereby 2640 lbs. of carbonic acid, for 100 lbs. carbonate of lime are composed of 43.6 acid and 56.4 of lime; but it is proved by experiment that a period of 20 years is required for all the carbonate of lime of this quantity of marl to be decomposed by the humic acid and the silica of the soil; and if the quantity of carbonic acid available to the plants amounts annually to 132 lbs., this will amount to an annual supply of only 36 lbs. of carbon. What can this small quantity of carbon avail the crops? One crop of Rye (3000 lbs. of grain and straw) contains more than 1500 lbs. of carbon! If, however, the soil should not contain so much humic acid (22,480 lbs.) as would suffice for the saturation of all the lime communicated to it by the marl, in the state of carbonate, in the assumed case of 20,000 lbs. per acre; then, the lime, leaving the carbonic acid, would unite with the silica of the soil into a silicate of lime—a substance which, being insoluble in water, cannot afford any nourishment to the plants. Still, silicate of lime will always be formed along with humate of lime; partly because lime and humic acid cannot be everywhere in contact throughout the soil, partly because so much humic acid does not at any one time exist in it as is necessary to unite with all the lime. Thus, a great disadvantage results for the plants, and the effects of marl-manure will cease the sooner (at least as far as the action of carbonate of lime is concerned), the more silicate of lime has been formed, which will be chiefly the case in very fine sands. The substance thus formed will, as we have seen before, be again decomposed by the humic and carbonic acids; but this process takes place so slowly, that it will benefit the plants but very little. A larger quantity, however, of silicate of lime may be decomposed by the nitric, chloric, and sulphuric acids, which are annually conveyed by the rain to the soil; and as soluble calcareous salts are thereby formed, it may be said that the plants are thereby supplied with some scanty quantity of lime. The carbonate of lime, again, may also cause the combining of the atmospheric nitrogen and oxygen into nitric acid, which unites then with the lime, and forms lime-saltpetre; still, the quantity of the salt thus formed is probably so small, that the advantage of it to the plant can scarcely be taken into account. The chief effect therefore of the carbonate of lime in marl is, that it combines with the humic acid already existing in the soil into a salt very advantageous to vegetation, and that, on account of its great affinity for that acid, it decomposes the coal of humus and other organic matters of the soil; although this is done in a far less degree than by caustic lime—that, moreover, by this process several other substances of use to plants—as potash, nitrogen, sulphuric acid, &c.—are developed and brought into play, as has been already stated in speaking of lime.

Besides the carbonate of lime, the carbonate of magnesia also is one of the chief components of marl. Its action upon humic acid, vegetable matter, and coal of humus, is similar to that of carbonate of lime, but less powerful, as it does not contain such a strong chemical base as the latter. With humic acid the carbonate of magnesia forms a salt, which is soluble in 160 parts of water, and is useful as food for plants. The effect, therefore, of the carbonate of magnesia contained in the marl must vanish sooner than that of carbonate of lime; the more so, as magnesia will also readily combine with the silica of the soil into a silicate which is insoluble in water. It may therefore sometimes be necessary to repeat a manuring with marl merely on account of the magnesia. The carbonic acid thus expelled by the silica and humic acid is not to be taken into account at all, because if any sort of marl contained even 30 per cent. of carbonate of lime, it scarcely ever contains more than 5 per cent. of carbonate of magnesia. Everything else which has been stated of carbonate of lime refers equally to carbonate of magnesia.

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. VII.

(Continued from p. 107.)

The Oleaginous Group.

Oil, fat, or wax, are contained in the cellular structure of many plants. The odour of plants depends upon the volatile oil which they contain. The fixed oils, such as olive, rape, and linseed oils, are obtained by crushing the fruit or seeds of the Olive, the Brassica, or the Flax plant. Their use is well known. All plants of the Beet tribe are rich in oil. Wax is not so easily obtained as oil; it may be procured by heat from the Poplar and other plants, and the well known manufacture of this article by bees proves its existence in plants, whence they derive the material.

A substance similar to tallow is yielded by a tree named the Croton Sebiferum, and a tree which abounds on the Malabar Coast, called Piney, bears a pulpy fruit that yields a large quantity of tallow, almost as firm as wax*.

The Oleaginous Group, as is well known, are produced in large abundance by animals. This is effected by the transposition of the elements of food; no food will produce fat that does not contain its elements. The importance of bearing this in mind by those who undertake the fattening of cattle, has been ably shown by Dr. L. Playfair, in the "Agricultural Journal." His lectures upon this subject contain an elaborate view of Liebig's doctrines and discoveries in this important branch of Chemistry.

The designed use of the Oleaginous Elementary Group in plants is evidently the support, the respiration, and animal heat of the animals that live upon the plants which contain them. Fat is not, properly so called, a part of the organism of animals. That portion of this Group which is not required to support respiration is deposited as fat in the cellular structure. *The carnivorous animals deposit no fat.*

The Albuminous Group contains the elements of food which are essential to the formation of muscle. Thus in beef, the fat is produced from the saccharine or oleaginous, and the lean from the albuminous or azotised parts of the food. The albuminous elements of food that exist in plants have an important office to fulfil in the economy of life.

From the first moment of existence to that of death, there is a continual decay of the tissues of the body in all animals. Motion cannot take place without the death of a part of the body. If a finger is moved, or a thought exercised, a particle of matter is destroyed. This can only be restored by the albuminous portion of the food. Its importance thus requires no further comment. Bread is aptly called "the staff of life" It gains its title to this character by containing flour of starch (non-azotised matter), and gluten (azotised matter), in such proportions as are exactly adapted for human food; so that a person who would die if fed upon Potatoes or Rice, or lean beef, alone, would thrive upon bread, which contains a union of the two great divisions of food.

The azotised group of the chemical constituents of plants are represented by three principles contained largely in vegetables; these are modifications of the same principles. They are fibrine, albumen, and casein.

1. *Of fibrine.*—If the juice expressed from a vegetable be allowed to stand, a green deposit will take place. When the colouring matter of this deposit is removed, a grayish-white substance will remain, which is vegetable fibrine. This vegetable fibrine is identical in chemical composition with the lean part of beef when deprived of its colouring matter. It is the principle which restores waste in the animal.

2. *Albumen.*—If we take a Turnip, or Mangold Wurtzel, or Cauliflower—crush it, strain off the juice, and subject this juice to a boiling heat, a congulum will form, which is identical in its nature and chemical constitution with the white of egg.* This is vegetable albumen. It is fibrine in its primitive form; organised by the vital principle it becomes the fibrine of muscle, of beef, mutton, &c. The egg contains albumen and fat, with a little sulphur; and yet, from the egg, a perfect animal is produced with flesh, feathers, beak, claws, and gelatinous bones. The albumen is in this case metamorphosed into fibrine (muscle) by the vital principle. Fibrine is converted into gelatine, whence the bones, beak and claws, feathers, &c. of the perfect bird. Thus we see that in a Turnip or a grain of Wheat we have the elements from which an animal can be formed.*

3. *Casein.*—From Peas and Beans, where it exists in the form of legumen, and from many other plants, a third principle can be obtained. This is Casein, which is identical with the curd of milk, from which cheese is made. Man and other mammalia are supported while young entirely by milk, which fact furnishes the only known instance where animal life is supported by one article of food. Now, in milk there are combined the essential elements of nutrition—sugar, oil (butter), which are non-azotised, and the azotised principle casein (cheese.)

It is impossible to glance at these beautiful facts, dwelt upon by Liebig and others, without being struck with the harmony and perfection evinced in the design of Infinite Wisdom.

Now, it is clear from the above statement, that if the perfect bird can be formed from the albumen and fat of the egg, the plant containing starch and gluten must be formed from matter containing the elements of starch and gluten. The analogy between the chicken and the plant does not cease with the formation of roots in the latter, and the breaking of the shell of the former. If not fed they die. Instinct and human care will support the bird. The vegetable instinct (if I may be allowed the expression), of the roots and leaves of the plants will provide for it nourishment from the air and soil. If this is deficient in the soil, or it is desired to increase the size and weight of the grain, then according to that deficiency or desire, it must be supplied in the form of manure by the ingenuity and wisdom of man.—*C. R. Bree, Stowmarket.*

Home Correspondence.

Importance of writing Plain English.—Now that your Paper, from its greater scope of objects, is likely to become of more extended circulation, I venture to suggest to you and to your correspondents, that in their communications they should avoid provincial or local terms of description, weight, measure, &c. Every locality has some *patois* of its own, which is of course better understood and much better liked there than elsewhere; but in a publication intended for general use, it is obviously necessary that none but purely English terms should be used. Only fancy what a hodge-podge the *Gardeners' Chronicle and Agricultural Gazette* would be, if each county alone were to send a specimen of its dialect—not to mention that the Welch, Irish, and Highland Scotch, might take it into their pens to address you in their tongue also! With reference to weights too, and measures both superficial and solid, the use of local denominations renders many useful communications only so many puzzles. In the market notes of prices, we have in Ireland, for instance, Wheat per bag of 20 stones, Oats per barrel of 33 stones, Barley per barrel of 36 stones in some places; while in others, the barrels are—of Barley 16 stones, of Oats 20, &c. &c. Then we have the Scotch Bolls, Firlots, &c. &c.; the Welch Peggot, and the Straw-quart. As to the weight of a stone, it varies as much in commerce as it does in geology. There cannot, in fact, be any better way of measuring Corn of all sorts than by the regular avoirdupois scale; all other modes should be abolished, as has been the case with respect to the admeasurement of coal. As to the "Muirland Gardener," who can quote from Dr. Lindley good classical English when he pleases, my sentence on him is, that if he uses any more of his reekie-peekie stuff, his horn spoon be taken from him, and he be obliged to eat his stirabout with a two-pronged fork for a month.—*Woodend.*

Effect of Winds on Vegetation.—In the *Gardeners' Chronicle* of last year, there were extracts of lectures published pointing out the analogies which exist between the process of combustion and the process of digestion in an animal's stomach. I need not say how important the analogies of nature are: they have often pioneered the way to important discoveries in science. Witness some of Sir H. Davy's discoveries. Following these analogies I have long been impressed with the belief that a current of air made to pass over vegetation promotes its vigour, in the same manner as one passing into a fire hastens combustion. Indeed, if plants appropriate a portion of the atmosphere to their sustenance in the same manner as an animal or the fire does, it is difficult to understand how currents of air, of varying density, can pass over them without affecting their health. When the wind blows we experience currents of denser volume than when the atmosphere is perfectly still. Plants, therefore, in the former case have opportunities of appropriating a greater amount of the pabulum they derive from the atmosphere than they have in the latter. These opinions, which I have long entertained, I was desirous of seeing confirmed or confuted by more extended observation, and I took the liberty of addressing a few queries to your paper upon the subject, in the hope that they would elicit some remarks from your readers respecting it. The instances of fertility to which I referred are not in upland districts. We can find exposed situations where the fertility is not impaired by want of climate. There is one within the range of my eye at the present moment; it is an eminence in the midst of a fertile plain, and, certainly, vegetation at this season is much more luxuriant upon its top than it is at the base. The shaking and stirring of plants by wind is an effect which is obvious to every one, but we do not often enough reflect that most of the operations of nature are carried on in secret, and that what we see ought only to be regarded as an indication of what we do not see.—*J. R.* [Luxuriance of vegetation on the summits of eminences greater than that occurring in vales, must generally be owing to a difference in the nature of the soil. If our correspondent would examine geologically the spot he refers to, we think he would find that its greater fertility is owing to a difference of soil, owing to a change in the nature of the subsoil on which it rests.]

The Chief Fertilising Qualities of Bones.—This is a

question of considerable importance to the farmers of the soils to which crushed bones are a fertilising addition, for erroneous views of its mode of action has led, through injudicious modes of application, to much disappointment and loss. That the decomposable animal matters do *not* form the *chief* fertilising ingredient of crushed bones is, I think, indicated in several practical ways. Thus the Cheshire farmers, who use the boiled or steamed bones of the Manchester size-manufacturers very extensively for their pastures, consider that for these the bones are certainly as enriching to the land, when nearly all the size and grease are removed by the process of steaming, as when the bones are in what they denominate "the green," or unboiled state—and the evidence does not conclude here:—the more skilful farmers, who use the crushed bones as an excellent drill manure for Turnips, have long since discovered that the fresh bones are not nearly so powerful as those crushed bones which have been fermented in heaps, either by themselves or with other fertilisers, until in fact the mass is reduced by the putrefactive fermentation nearly to the same appearance as garden mould. By this process it is true that the proportion of carbonate and phosphate of lime remains unaltered in the remains of the bones, but then almost all the purely animal matter is dissipated in the gaseous form. Volumes of ammoniacal matters are evolved, and yet still the farmer finds that the crops of Turnips he can produce with the fermented or nearly-decomposed bones are far superior to those grown with the unfermented. I am not aware of any very valuable experiments with calcined bones, but there are several very recent experiments, to which I need hardly refer your readers, upon the application of sulphuric acid to bones, which clearly support the same conclusion, for from these it appears that the fertilising properties of bones are certainly not impaired by this process, although by the action of the sulphuric acid on the bones, a very considerable chemical action takes place, the animal matters of the bones are decomposed, and a very large portion of their constituents are evolved in the gaseous state. It is very likely, I think, that all the reported advantages of this new mixture of sulphuric acid with bones may be obtained at much less expense to the farmer by mixing a portion of gypsum (sulphate of lime) with well-fermented crushed bones, (?) but still I cannot but consider these experiments as affording additional evidence that it is not the decomposing animal matters of the bones which furnish their chief fertilising properties, but that their agricultural value must be attributed chiefly to the copious presence of the phosphate of lime.—*Cuthbert W. Johnson.*

Shed-feeding of Sheep.—Foot-rot.—When offering a few remarks lately respecting the confinement of sheep in sheds, I felt disposed to introduce something respecting the probability of their becoming affected with the foot-rot from want of the liberty of rambling, but I abstained from doing so from the apprehension that such reference would have been considered hypercritical or visionary by your readers. Yet, as I perceive in your publication of the 3d inst., a coincidence between the notion which then occurred to me, and an alleged fact related by another of your correspondents, in the communication which succeeded mine in the same column, I take the liberty of sending you a few addenda to my former letter, suggested by the information conveyed by Mr. Grey, of Dilston. That gentleman states in substance that he had confined sheep in sheds, and occasionally with successful results; but that the advantages which he derived were overbalanced by a virulent disease in the feet, which was either the foot-rot or some modification of it. Now, sir, the experience of Mr. Grey on this subject goes farther than the point on which it directly and primarily bears, viz., the expediency of feeding sheep in sheds; for it has an important bearing also on the discussions which have taken place respecting the cause of the foot-rot. Warm moisture has been assigned as the origin of that malady, and I venture to say with good reason: moist pasturage in a warm season of the year induces evaporation that becomes noxious to sheep, from the circumstance of their lying with their feet folded under their hearts, in the manner most calculated to produce great heat and moisture, which also affects their bedding in the sheds, and generates, in Mr. Grey's opinion, an ailment similar to, if not identical with, the genuine foot-rot. Inflammation of this nature does not arise (unless infectious matter has been deposited on the pasture-ground by other sheep) in flocks that have a short dry pasturage, and sufficient liberty of range; it is on rank grass in low land, and generally moist pastures, that the foot-rot is found to exist. Sheep that have a considerable way to walk in search of their food escape this affliction, which, like the gout in the human race, is a frequent attendant on a life of sloth and voluptuousness. They may have galled feet from over-travelling, but not the foot-rot, which seems to have been the effect of the increased weight and consequent inactivity of the large varieties. I am aware that a different theory has been adopted by eminent veterinarians respecting the foot-rot—that some high authorities among them attribute it to the deformed structure of the hoof from overgrowth, through want of the friction which rough land supplies to pare it down, or the neglect of the shepherd to trim it with his knife; but I cannot conceive that the distorted form of the hoof occasions the malady in question, which appears, with far more probability, to arise from moisture under the particular combinations calculated to render it the chief agent in developing the ailment. Mr. Grey may perhaps recollect whether those of his sheep which became diseased in the feet had any deformity of structure in the hoof previously to their being confined in the sheds. I fancy that he will not attribute the effects which he witnessed to any preceding want of natural or artificial hoof paring. Neither has repeated experience, nor mine, shed any degree to prove that sheep in actual preparation for the butcher may not be fattened with great advantage on Mr. Childers' system, while they harmonise with the convictions of those sheep farmers who consider that exercise is essential to the health and hardihood of their flocks, and that close confinement in sheds and small yards, in a state of unnatural warmth, and amidst the effluvia which arises from fermenting litter, must be more or less prejudicial to sheep, excepting those which are to be transferred at once from their prisons to the shambles.—*Martin Doyle.*

On Flax Culture.—I had no idea that you would publish any part of my former letter on this subject; and as you have thought proper to publish a part and not the whole, I hope you will now find room for my explanations of assertions, which must, from the amount of profit named as being realised by the culture of the Flax plant, appear to some of the old school of farmers a regular delusion. I beg leave to hand you a pamphlet from the Belfast Flax Society, which, in pages 7 and 16, will corroborate the facts represented by me so far as prices go, and as for the expenses incurred, I venture from my practical experience to lay before your readers the following plain statement:—I have told them 60*l.* per acre can be made by the cultivation of the plant; it is but fair I should show such a result is to be accomplished. The following are the particulars of the expenses of growing an acre of Flax in Ireland, and the profits derived from the same:—

An acre of land, including taxes	£2	5	0
2½ bushels of seed	1	10	0
Ploughing and sowing	0	10	0
Weeding, 12 hands at 8*d.* per day	0	8	0
Pulling, 12 hands at 1*s.* „	0	12	0
Watering, 7 hands at 1*s.* „	0	7	0
Scutching, 70 stone at 10*d.* per stone	2	18	4
Lifting, &c. &c., 10 hands at 1*s.* per day	0	10	0
Carting to mill and market, ½ ton	0	19	8
	10	0	0
Produce according to Mr. Denman's account in page 16	£70	0	0

Thus, Mr. Editor, a profit is shown of 60*l.* These particulars I am prepared to prove, and if any of your readers desire further information, I shall at all times feel pleasure in affording it. As several gentlemen have expressed a wish to obtain a work on the subject, it is my intention to put together such information and instructions on the cultivation of Flax, as may be advisable to follow in order to grow the finer qualities, as I must repeat that it is much to be regretted that our French and Belgium neighbours should take from us five millions of pounds sterling annually for Flax, an article that our farmers can and ought to grow themselves.—*J. H. Dickson.*

Number of Gallons in Tanks of various Forms and Dimensions.—The following is a Table showing the contents in gallons of square-built and of circular tanks of various dimensions:—

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

The Council having referred the communication made to them at their last meeting by his Grace the Duke of Richmond, on the results obtained by the application of sulphuric acid and bones, as a manure for Turnips, to the Journal Committee, Philip Pusey, Esq., M.P., the Chairman of that Committee, has recommended to the Council the publication of the following reports on that subject:—

I.—The Duke of Richmond's Experiments.

Experiments made on Turnips with five different kinds of manure, on the farm of Gordon Castle, in the year 1843. The seed (Dale's Yellow Hybrid) was sown on the 15th of June, and as it was wished to ascertain the result while the Duke was at the Castle, the Turnips, before they came to maturity, were taken up on the 3d of November, and carefully topped and weighed.

1st.—One imperial acre, manured with 8 bushels of bones and 14 cubic yards of farm-yard dung, at an expense of 3*l.*, produced 12 tons.

2d.—One ditto, manured with 2 cwt. 91 lbs. of guano, at an expense of 1*l.* 17*s.* 4*d.*, produced 11 tons 4 cwt.

3d.—One ditto, manured with 16 bushels of bones, at an expense of 1*l.* 16*s.*, produced 11 tons.

4th.—One ditto, manured with 83 lbs. of sulphuric acid and 2 bushels of bone-dust, mixed with 400 gallons of water, at an expense of 11*s.* 6*d.*, produced 12 tons 4 cwt.

5th.—One ditto, manured with 83 lbs. of sulphuric acid, mixed with 8 bushels of bones, and sown with the hand, at an expense of 1*l.* 5*s.*, produced 11 tons.

(Signed) Thomas Bell, Farm Steward.

II.—Dr. Manson's Experiments.

My field of twenty-one acres was last autumn deeply ploughed with three horses out of Oat stubble, it having previously carried a Wheat crop after two years' ley, well manured. In the spring it underwent the usual process of cleaning, and received about the 1st of June, twenty-five quarters of Linksfield lime. Drilling and sowing commenced upon the 10th, allowing four bushels of bones and ninety-six pounds of sulphuric acid, properly diluted with water, to the acre. The manure was prepared by putting into a large vat, placed in a corner of the field to be sown, thirty-two bushels of bone-dust; and for each bushel was added ninety-six pounds of water, and twenty-four of sulphuric acid; there were thus in the vat at once 32 bushels of bones, 384 gallons of water, and 47½ gallons of sulphuric acid. The whole was allowed to lie for a fortnight previous to use, when it was found that the acid had nearly dissolved all the bones. The mixture was then drawn off and added to water, in a large water-cart, in the proportion of one gallon of the mixture to 50 of water, and it was distributed to the drills from three spouts into three drills at a time. The drills were previously slightly harrowed down, and immediately drilled upon receiving the liquid manure. Owing to the great drought which prevailed at the time of sowing, and the very recent liming, very few of the seeds vegetated till after the rain, which fell about a month from the time of sowing. The heavy gale which prevailed about this time cut down the greater part of the early plants, and has thus left the field deficient in some places. I observed that after the field came to be singled, it underwent that process in the order in which it was sown; 13 acres having been sown with farm-yard manure, and the remaining 8 with the bones and sulphuric acid, the plants from the acid keeping the lead of those sown with court manure, and are to-day a heavier crop, though not looking quite so healthy in the blade, owing to their having come earlier to maturity. The expense, 1*l.* per acre, viz., 4 bushels of bones, at 2*s.* 6*d.*, 10*s.*; sulphuric acid, 96lbs. at 1½*d.*, 10*s.* Those laid down with court manure received 20 cart-loads per acre, at 2*s.* 6*d.* per load, 2*l.* 10*s.* Weight, per Imperial acre, as ascertained on 15th November, the date of weighing:—

	Tons	cwt.	lbs.	
Sulphuric acid and bones	12	5	96	per Imperial acre
Court manure	10	17	104	ditto

Spynie, Oct. 20, 1843. (Signed) D. D. Manson.

ROYAL AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

At the Special Meeting of the Council on the 15th inst., a letter was read from Mr. Charles M'Donnell, of Clifden, in the county of Galway, accompanying a specimen of dried Seaweed, pulverised, which he had prepared in great quantities, believing it to be a most valuable manure for raising Turnips and other green crops. Means were then taken for collecting subscriptions in Dublin, &c. towards the expenses to be incurred upon the occasion of the Great Meeting of the Society in Dublin on the 14th and 15th August next. The re-adjudication upon the bulls belonging to Messrs. Grey and Hill, about which a difficulty had arisen since the last General Meeting of the Society, was directed to take place on the 15th of April.

FARMERS' CLUBS.

Ayrshire Agricultural Association.—Professor Johnston delivered a lecture on Agricultural Chemistry to this Association, at Ayr, on the 30th ult., from which we extract the following:—"There are certain substances which are special to certain plants. Some plants require more alumina, potash, magnesia, &c. than others, and it is the key to successful Agriculture to know what particular ingredients in the soil every description of plant requires. A certain soil, for instance, may require more potash, magnesia, &c. for a particular crop, and yet that soil may be capable of yielding a very good crop of something that requires less of these ingredients. If you want to grow *a*, *b*, *c*, you must make the soil perfect in the substances necessary for all; without this it may grow *a* and *b*, but may be defective in that which is necessary for *c*. When you wish it to grow *c*, therefore, you must add what it wants for that purpose. Let me give an illustration of how it may be that a comparatively

fertile soil cannot be brought round by the ordinary application of farm-yard manure; how it may appear that a soil, generally fertile will yet refuse to grow a certain kind of crop, and that although farm-yard manure be applied, still it will not give a very good crop of the particular description of grain wished for. Why is this? The conclusion that we have just come to accounts for it, namely, that the manure does not contain all the substances which the soil wants. This case is exemplified in the Carse of Gowrie. The farmer there manures as usual with farm-yard manure. From the soil manured in this way he may get a good crop of Turnips, but not of Clover. After having let a year run over, he may sow Clover, and the reason of this is, that the substance necessary for growing Clover is not contained in sufficient quantities in the farm-yard dung applied during the first year, and that it is only after a second application that the requisite quantity is obtained. The first quantity of manure that he applies—suppose 40 yards—contains, it may be, a portion, but not a large enough portion, of that substance which is necessary to ensure a good crop of Clover; he is thus debarred from growing Clover for that year, and it is only in the second year—when he has added another 40 yards of manure—that a sufficient quantity of that particular substance is collected. Suppose that this substance may be magnesia or soda, what a large expense does he not incur by adding 80 yards of manure; whereas, had he been aware of the principle upon which the growth of plants depends, he might have attained his object in the first year by giving the land an extra dose of magnesia or soda, at the expense, perhaps, of a few shillings! Thus we come to understand how a knowledge of the principles upon which the cultivation of the soil rests, acts upon the profits of the agriculturist—how his knowledge or ignorance of these principles comes home to his pocket."

Collingham.—The monthly meeting of this club was held on the 6th of Feb., when 35 to 40 members were present. It being the anniversary meeting of this Society, the officers had to be chosen, most of them being re-elected, except the secretary, who resigned. A lecture upon the Making and Repairing of Roads was delivered by Richard Parkinson, Esq., of Knapthorpe, whose thorough knowledge of the subject, obtained by long experience, enabled him to illustrate it in a very satisfactory manner. In his description of the formation of a new road, he commenced by recommending that it should have a close, firm, compact foundation; and that the soil underneath should be well drained, so as at all times to give the road a dry and firm foundation. He then suggested that a layer of Ling, Gorse, or straight Thorns should be laid; and above these a covering of sand free from gravel, and when this was sufficiently rolled by the action of carriage-wheels, he advised the application of the first covering of material, which should be limestone, if it can be had, or otherwise good clean gravel free from boulders, and mixed with a little lime. The road must be kept level with the rake until it is sufficiently firm to receive the second covering of gravel or material, after which less care will be required. The lecturer confined himself chiefly to gravel-roads, that being the most obtainable material in the neighbourhood. The mode of applying the gravel deserves particular notice. The necessity of separating it, by riddles at the time of getting it, into three sizes before it is applied, was urged. The expense of doing so will only be about 2½*d.* per ton; and the advantage of doing so shows itself in the greater ease with which, in roads so made, the surface is kept perfectly level. The coarsest material is laid first, and the finer sorts may be placed above it in layers one inch thick, and in stripes covering about one-third of the width of the road at a time, so that carriages may avoid the gravel, and a pleasant and safe road is then insured at all times of the year.

Halesworth.—At the meeting of this club on Feb. 2, a discussion took place as to "which is the most valuable root, under general circumstances, Beet or Swede Turnip." The gentleman who introduced the subject considered that the crop of Beet averaged several tons per acre more than that of Swedes, and taking this increased weight on light lands at only one-fifth part per acre, the advantage, if the Beet possesses equal fattening qualities with the Swede, must be very great, whilst on the heavy lands there cannot be a doubt of its superiority. Another advantage arose from the greater facility of getting off the Beet crop. Another member considered that a crop of Beet can be more certainly depended upon than a crop of Swedes; and, further, that Beet can be readily kept, and are excellent food throughout the season. It was also stated as the result of experience that the Beet had decidedly the advantage over the Swede, as regards the Barley-crop succeeding them; the same plan being pursued with regard to both, viz., both being got off the land at the same time, and the tops of both being ploughed in. An intelligent butcher gave it as his opinion that the meat was equally good whether the cattle were fed on Beet or Swedes. A gentleman whose opinion carried the greatest conviction—his practical experience and general business habits leaving no doubt of the correctness of his observations—submitted the following experiment, which he had made to ascertain the relative value of the two roots as regards their fattening properties; and stated, also, his belief that on an average land which would produce 25 tons of Beet per acre, would not produce more than 15 tons of Swedes, the lands being manured equally well, and treated alike in every particular. Ten beasts, averaging about 60 stone each, were put upon Beet-root. Each beast consumed about 15½ cwt. of root sliced, and 3½ stone of cake per week; therefore one acre of Beet-root, producing 25 tons, would feed one beast 33½ weeks, allowing in addition 7lbs. of oil-cake per day. Twelve beasts, weighing about 60 stone each, were put upon Swedes, and also [illegible] of Swedes and 5½ stone of oil-cake per week. Eighteen tons of Swedes is supposed to be a fair average crop in this neighbourhood, and such a beast would thus consume that quantity in 20 weeks, with the addition of the 3½ stone of oil-cake per week. It thus appears that assuming the above quantities to be the average produce, an acre of Beet would last a beast 13 weeks longer than an acre of Swedes. The animals appeared to do equally well on either root.

It was resolved, that the opinion of the members present is decidedly in favour of the Beet-root over the Swedish Turnip under general circumstances, its weight per acre of the former, being much greater than that of the latter, and its fattening properties being fully equal in every respect, with this additional advantage, that the Beet is equally valuable as a food throughout the whole season.—*W. Reynolds, Secretary.*

Reviews.

On Thorough Draining, and its Immediate Results to Agriculture; being a Paper read before the Wakefield Farmers' Club. By John H. Charnock, Land-Agent, and Secretary to the Yorkshire Land-Draining Association. Rowland Hurst, printer, Wakefield.

This is a pamphlet which is likely to be practically useful to the farmer and landowner. We extract the following remarks upon the importance of drainage being executed efficiently and permanently, and on the necessity, therefore, of its being done chiefly at the cost of the landowner:—

"If there is one operation more than another in which the maxim that 'what is worth doing, is worth doing *well*,' holds good, it is in draining; *effective* and *permanent* must be your work, or it is comparatively money and labour thrown away. And for this reason, if for no other, should it be done under the superintendence of the landlord; it is in truth an owner's work; it is *principal invested*, and cannot, except by an occupier, be with justice treated as a mere outlay for repair. It is a permanent improvement of the fee, and if *permanently and effectually* done, gives as surely a rental fully commensurate with the outlay. At the same time, however, *rather than farm undrained land*, it is the palpable interest of the occupier himself to undertake the work, and especially if he previously concludes for any certainty of tenure. But the most desirable arrangement is, that owner and occupier should act mutually in the matter, and as the best interests of each are so intimately bound together, they should mutually concur in the execution of the work. And here I may mention the plan which is adopted on the Greenwich Hospital estates in Northumberland, under the superintendence and by the advice of that eminent Agriculturist, Mr. Grey, of Dilston, which I think may be considered as perfectly equitable and unexceptionable in all cases. The rule is this: if the drainage is done during the *first* seven years of the lease, the Hospital pays *one-third of the entire cost*; if during the *second* seven years, *one-half* the cost; and if in the *last* seven years of the term, it pays *two-thirds* of the cost of draining, assuming the lease to be for twenty-one years."

Mr. Charnock gives details of the amount of this cost, and means of diminishing it are pointed out; thus at p. 12 it is stated—

"That a due regard is not usually had in the cutting of the drains, so as to economise the labour consistently with full efficacy of operation. I allude especially to their being cut much wider than is necessary; considering that tiles of a very much smaller* area than are ordinarily used would be fully as effective; at all events, the higher extremity of each drain might be laid with them, and the size be increased in regular gradation as you descend to the outfall. It does not require to have a regular *grave* in your flesh to make it *bleed*—a *simple cut* is enough, and just so with the soil—only divide it ever so little, and *keep the sides of that incision asunder*, the water will flow, without converting your drain into a ditch."

There are some of the Author's suggestions in which, however, we do not acquiesce. Thus, it is recommended that some porous substances, as broken stones, be filled into drains above the tiles. The usefulness of doing this depends on the rain-water, as it falls upon the land, flowing over its surface down the declivity—the sides of a ridge, for instance—till it reaches the drain (which, if this theory be correct, should always be in the furrow), and there sinking through the porous material into the channel. But it should be the aim of the farmer to get rain-water to sink into the land just where it falls, and thus to find its way to the drains underground. Instead of having porous lines through his land every 16 feet, which this mode of draining would give him, it should be his aim to get *the whole* of the land sufficiently porous to a depth of 16 or 18 inches; and, when it is conducted properly, there are very few soils on which the operation of subsoil-ploughing will not produce this porosity. Land in this condition will allow no surface-water to appear; the rain as it falls sinks at once, and finds its way to the drains underground.

We also object to Mr. Charnock's plan of using tiles without soles to support them in the drains. We quote the following from a lecture delivered before the Highland Society of Scotland, by Dr. Madden, of Penicuik, near Edinburgh.

"It is stated by many practical men, in regard to tile-draining, that when the subsoil consists of very stiff clay, the tile-soles may be dispensed with, and as the soles are somewhat costly, the farmers are willing enough to give them up, especially when they find that others have done without them, and yet their drains have continued to run well for some years. If, however, the opinion of a scientific person had been requested, he would at once have stated, that unless the drains rested on the surface of a rock, the tile-soles could in no instance be dispensed with, because, as Prof. Johnston justly remarks, '*There are no clays which do not gradually soften under the united influence of air and running water.* In the course of 10 or 15 years, the stiffest clays will soften and allow the tile to sink, and many very much sooner. The passage for the water is thus gradually narrowed.'"

It is right to say that the tile which Mr. Charnock considers capable of acting alone, is of a peculiar form, the edge on which it rests being widened in order to hinder it from sinking. Although we differ from the author of this pamphlet on these points, yet we cordially recommend his work to our readers. It contains many useful remarks on the practice of drainage, and much sound reasoning upon the effects which would follow its general adoption. We entirely agree with the author in the spirit of his concluding paragraph.

"Agricultural Societies might add materially to their usefulness, and to the general good, by directing their attention somewhat more palpably towards the improvement of the *soil*; bullocks, sheep, and pigs are now all fully up to the mark, let us see if the *land itself* cannot, under the same auspices, be brought into something like a corresponding state."

Mr. Charnock is secretary to the Yorkshire Land-draining Association, which has secured the services of Mr. Smith, of Deanston, as draining engineer. "This Association is formed for the purpose of affording to the Agricultural interest, by means of its collective capital, the funds necessary for the thorough draining of land;" without which these funds cannot be economically and efficiently applied; and now that capital as well as capability of applying it may be had on reasonable terms, there is reason to hope that the work of Agricultural improvement will progress rapidly; and in districts where tenants have a lengthened interest in their farms secured to them by lease, we have no doubt that the facilities afforded by Associations like this will be eagerly taken advantage of.

* "Mr. Thomas Hammond, of Penshurst, now uses no other size for the parallel drains than the *inch tile*, and it may be here stated that the opinion of all the farmers who have used them in the weald is, *that a bore of an inch area is abundantly large.*"—*Report on Drain-Tiles and Drainage, by Mr. Parkes.*"—*Journal of the Royal Agricultural Society of England, Vol.* iv., *Part* ii., *page* 373.

Miscellaneous.

Improved Method of Sowing Wheat.—After the destruction of so much of the young Wheats late in the spring of last year, it occurred to me, that by adopting a different method than what is at present practised in planting the seeds a similar disaster might in future be prevented. My idea was this:—to plough down the seeds, and that in such a way, if possible, as that the braird may come up in rows at equal distances between the drills; and instead of the usual practice of harrowing immediately after sowing, to allow the drills as left by the plough to remain entire throughout the winter and spring. The furrows, or drills, left in this manner, would, I am persuaded, form a shelter to the plants against the frosty winds which generally prove more or less destructive to Wheats in the months of March and April. In the case of drift, which is sometimes hurtful, the drills would retard the snows filling up the openings between them, thus covering up the plants in perfect safety from the changes in the atmosphere. Independent of drift, we have often a course of dry withering weather in spring, with strong sunshine during the day, which, with frosty nights, generally prove very injurious to young Wheats. Against this danger the drills, by the action of the weather, would be continually operating; for, mouldering down they would give, as it were, a constant hoeing to the plant, keeping the tender stem warm and dry.—*Correspondent of Ayrshire Agriculturist.*

Furrow Drainage.—For effectual furrow-drainage, the drains require to be made 30 inches deep, 20 inches broad at the top, and about 5 at the bottom, each drain 6 yards apart. They are to be laid with suitable concrete tiles, either made with moulds or made in the drain, or filled to the depth of 9 to 12 inches with stones, properly prepared, if to be had in the neighbourhood, with suitable soles where required, and these covered with large gravel to the depth of 6 or 8 inches, or some suitable substitute, upon which the soil taken out will then be used for filling up with. The tiles are to be made of Concrete or Hedderwick lime and gravel, mixed up with water to a proper consistency. When the field has been thus prepared, it is then to be worked to the depth of 12 to 15 inches with the subsoil-plough, according to the nature of the soil. A Scottish acre will contain about 900 yards, or 150 roods of six yards each, of drains, and will, therefore, require about 2700 tiles, each 12 inches long. It is understood that a boll of lime, with a proper proportion of gravel, will make about 1000 tiles of that length. The cost of the whole, with soles where required, filling up the drains, cartage, and any other extras, will amount to from 2*l.* 10*s.* to 3*l.* per acre. Mr. Gladstone proposes, that those of his tenants whose farms are under fifty arable acres, should drain and plough in the manner above stated, and in the present season, not less than 2½ acres; about fifty and under one hundred, not less than five acres; and those above one hundred, after the rate of not less than five acres for each hundred acres. In consideration of such work being done effectually and thus completed, to the satisfaction of Mr. Sheriffs, or some other competent judge to be appointed by him, Mr. Gladstone agrees to pay to each of his tenants the sum of 3*l.* per acre, and to charge each of them with interest thereon at

the rate of 4 per cent. per annum, in addition to their rents, from the dates of the payments to the expiration of their leases, and nothing more:—also, in order to encourage his tenants in this undertaking, he engages, in addition, to allow to each, who shall complete the work described within the present season, an abatement of 10 per cent. from their rents from the last crop.—*John Gladstone*, London, 11th March, 1843.

Estimated cost per acre Scottish.

Montrose Review.

Destruction of the Weevil.—A liberal application of strong lime-water, with a brush, to the floors and walls of the granary, will effect its destruction; and a few days afterwards, the floor must be scoured with soap and hot water, or the future corn placed upon it will be injured by the dust of lime.—*Oxford Herald.*

Notices to Correspondents.

Our Correspondents will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

Communications from the following Correspondents are in type, and are only waiting till room can be found for them:—*P., A. C. Herrocastle, J. West, W. Billington, Herbert, M. J. Berkeley.*

Agricultural Architect.—*A Subscriber.*—Mr. Newland, assistant to Professor Low, University, Edinburgh, is the only person we know who devotes himself exclusively to this branch of business.

Agricultural Colleges.—*A Subscriber.*—It is the shame of our country that it contains no public school of Agriculture. There is a Lectureship on Agriculture annexed to the Edinburgh University, and at Abermoyle, in North Ireland, there is a College of Agriculture; but in England there is nothing of the kind. The Fairford Farmers' Club, urged on by Mr. R. J. Brown, of Cirencester, have, however, taken measures, which will, we hope, speedily result in the establishment of some such institution in that neighbourhood.

Analysis of Subsoil.—*Novice.*—Your analysis is inadequate as a guide by which to answer your question. It does not mention lime, although you speak of the presence of chalk. If the land is worn out, try plenty of manure, farmyard dung, or bone-dust, or guano, the first year, and afterwards grow enough green crops, by the consumption of which on the land you may preserve its fertility. You must not trench-plough yet; subsoil-plough it. This can be done by a two-horse implement. For answer about Grasses, next week.

Books.—*G.*—Martin Doyle's "Practical Husbandry," and Professor Low's "Elements of Practical Agriculture."

Bones.—*C. W. K.*—Autumn is the best season to apply lime. Bones form an admirable manure for Turnips on light soil.

Experiments on Manures.—*W. E. Rendle.*—We shall be glad to hear your reports on this subject, but cannot pledge ourselves to publish them all.

Food for Pigs.—*G. C.*—For pigs, Peas, &c. should be ground; for sheep, and all animals chewing the cud, this is not necessary. Your cask above the steam-boiler is as simple an apparatus for steaming food as you can have. There is necessarily a waste of steam; it passes through the Potatoes; and a portion escapes in the best machines of the kind. The want of success attending the application of grain in certain instances must be owing simply to the pre-existence in the land in sufficient quantity of the substances which guano contains.

Frozen Turnips.—*Anglus.*—Ewes with lamb will not injure themselves by eating frozen Turnips.

Guano.—*Vigil.*—Do not mix lime with guano; it will render its ammonia volatile.——*H. C. S.*—We do not know if it has ever been applied in the field in solution; but, unless during wet weather, it is the best way of using it. See third answer in this section of last Paper.——*A. O.*—Mix 3 cwt. per acre well with the soil in the bottom of the drills before you plant Potatoes. This can be done with a horse-hoe.

Hopetoun Oats.—*Gowyn.*—This variety is distinguished by its productiveness, and the quantity and nutritiousness of its straw. Turn your compost repeatedly, and apply to any green crop. If the soil is light, the proposed treatment of it will be beneficial. We prefer bones to the guano under the circumstances.

Italian Rye-Grass.—*C. N. N.*—If your land be in good order you have *a chance* of a crop of Hay from seed sown this spring; but your much better plan would be to plough the stubble immediately, and work the land well this spring, and take a crop of Swedes, or other roots.

Lichens as Manure.—*T. P.*—We know of no instance in which Lichens have been gathered for this purpose.

Liquid Manure.—*G. C.*—The expense of a water-cart is not one of the items to which a plan of saving liquid manure *necessarily* subjects the farmer. Indeed, he hardly needs a tank. If a small cistern be placed to receive the runnings of the stable and cattle-stalls, the water may be baled out of it every other day or so, and thrown over heaps of dung, earth, &c., placed by it for the purpose, and this will preserve it as well, or even better, than if it were accumulated in a large tank, and carted to the field in a water-cart. The best way of using liquid manure is to soak earth and dung with it in this way; there is a difficulty in spreading it uniformly in any other way, especially on sideland ground, with a water-cart. If the volatile ingredients of the liquid manure be fixed by adding sulphuric acid, it may be used at once; if not, let it putrefy before using it. It thus has time to absorb carbonic acid from the air, and in a degree to lose its causticity, but at the same time it loses much ammonia. A good water-cart can be made by attaching to a 100 gallon cask a pipe pierced with holes, to scatter the water; carry it to the field on a frame supported by a pair of cart-wheels.—*K.*—Dig a circular hole, 8 feet deep and 12 feet in diameter, pitch the bottom, and build a stone and lime facing 18 inches thick. Soak your dung-heaps with the water. Pare and burn old Grass land you intend to break up; plough the ashes under, 3 inches deep; harrow; cross plough 6 inches deep, harrow, &c., and take a crop of Turnips. We do not know the Malta Turnip. The Orange Globe is the best.—*M. Wartzel.*

Limestone as Manure.—*Becca.*—If the marls you refer to are those of the new red sandstone formation, which occur in considerable extent around Exeter, then they are very *slightly* calcareous, and they differ materially from the crushed limestone you allude to, inasmuch as that is almost *wholly* calcareous. The value of marl as a topdressing for land often, however, depends on the presence in it of substances occurring in very minute quantities, and not necessarily upon the quantity of the lime which it contains. (See articles on this subject, translated from Sprengel, in this Paper.)

Lucerne.—*G. B. Fortnes.*—Next week.

Mangold Wurtzel.—*Tyro.*—Don't sow till mid-April. We shall refer to this matter before then.

Manures.—*A Subscriber.*—Cut the carcases up into small pieces and bury them in good vegetable-mould; they will ultimately rot and incorporate with the mould, so that you will soon have a homogeneous mass fit for ploughing under as manure. It is always the more profitable plan to pass green food through the stomach of animals, and thus extract those materials in them which are identical with the constituent parts of beef, mutton, &c., *before* ploughing them under as manure. It must be believed that, by this process, they are injured as a manure, though not so much, but that their lessened value is more than made up by the value of beef, mutton, &c., obtained by their consumption.

Marl.—*Agricola.*—Grub up the Heath and burn it; do not burn the peaty earth below it; cart 100 cubic yards per acre on the land, and spread it before winter; plough it under in spring.

Mineral Manure.—*John W. Lloyd.*—You speak of petrified vegetables, as if the applicability of this term to any substance proved it to be a valuable manure. You do not keep in mind that the process of petrifaction entirely changes the nature of any substance that is subjected to it. As each particle of the vegetable which is undergoing petrifaction is washed away, its place is supplied by one of mineral matter, so that ultimately its composition is entirely changed, and according to the nature of this matter, are the properties of the future petrifaction. Flints are in many cases petrified sponges, and, however much sponges, from having once been the tenements of living animals, might be preferable as a manure to merely vegetable matter, no one would ever think of applying pounded flints in this way. The fact of your rock having *once* been a mass of vegetables, therefore proves nothing as to its *present* composition. The only way to ascertain that is by chemical analysis; and we repeat it, the statement you give us on this head is, with but little variation, true of most of the soils in the country. The per centage of magnesia, in one specimen you refer to, is large, but this earth is not always a desirable ingredient in soils. There is no doubt of the fact, with which you appear to be fully impressed, that the fixed ingredients of plants are essential to their luxuriant growth; but when speaking of these in determining on a proper manure for the soil, it is not the silica, nor the alumina, nor the oxide of iron, nor is it always the lime to which we refer; but it is the soda and potash, and phosphoric acid, those substances occurring in small quantities, and of which your analysis makes no mention, that we ought to take care of. We do not know how, from our previous remarks, you could have inferred our opinions as to the suitableness of your land for Peas, Clover, Turnips, &c.; that depends on its texture, &c., and upon the mode in which it is and has been cultivated, with all which particulars we are unacquainted.

Pigeon-Pea.—*A Constant Reader.*—We are informed that Vetches are often called "Pigeon-Peas," and the common Poplar Pea is also called so sometimes. Both of these are occasionally ploughed in green for manure; but we know of no Pea to which the name "Pigeon-Pea" solely appertains, except a tropical plant called by Botanists, Cytisus Cajanus.

Salt and Lime.—*M. D.*—The lime should be *dead* when it is used, *i. e.*, it should be a carbonate. The water of the salt is of little consequence in the process which ensues. The carbonic acid of the carbonate of soda which results is obtained from the lime. At twenty miles from the sea your land should contain salt enough; but try a small experiment on your Grass, and see if it benefits from a salt top-dressing. Thanks for your offer.

Soils.—*J. W. Lloyd.*—The fertility of a soil is better ascertained by comparing its treatment with its produce, than by analysis. Your nodules of limestone are not coprolites; if they occur in plenty, they may be advantageously burnt for lime.

Soot.—Put 30 to 40 bushels on an acre *now*. It does not *require* admixture.

Steeps for Seeds.—*H. B.*—Any direction on this subject must as yet be founded on mere theory. We shall shortly publish articles on the mineral constituents of agricultural plants, and then you can judge in this matter for yourself, for the object of the operation is to increase the quantity of these mineral constituents.

Tacking Sheep and Young Cattle.—*Gowyn.*—4*d.* to 6*d.* per week for your sheep, and 3*s.* 6*d.* to 4*s.* for your cattle, on Swede Turnips.

Tithe Commutation—Apportionment of Rent-charge on Woodland broken up.—*Constant Reader.*—Woodland broken up before the Commutation of the Tithes, will be subject to have a portion of the Rent-charge apportioned upon it.

Tobacco, Wool.—*Anglus.*—The duty on unmanufactured Tobacco, whether from Foreign countries or British possessions, is 3*s.* per lb. We presume that our Correspondent is aware that the growth of Tobacco for sale in this country is prohibited. Wool may be exported on payment of a duty of 1*s.* the cwt.

Wheat-Sowing.—*Wm. Steele.*—You have come to a right determination, we think, in sowing Wheat rather than Barley. Shirreff's White Wheat, known in Scotland by the name *Hopetown*, is one of our best spring Wheats; Red Straw White Wheat is also a good variety. We think Messrs. Barett and Exall, of Reading, manufacture a horse-hoe for Wheat; but we have no experience of it, having always hoed our Wheat crop by hand. The best plan of sowing Clover-seed is by means of the hand broadcast sowing machine, price 4*l.* This scatters the seed over the growing crop of Wheat, and it is covered by a single tine of the harrows across the drills. We shall be very glad to receive from you a report of your experience in transplanting Swedes rather than drilling the seed.——*J. W., Worcester*, will find the work advertised, col. *e*, p. 96.

*** As usual, many communications have been received too late for answering this week.

Markets.

SMITHFIELD, Monday, Feb. 19.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s	8	to	4s	0	Best Downs & Half-breds	4s	0 to 4s 6
Best Short Horns	3	4		3	8	Best Long-wools	3	10 4 2
Second quality Beasts	3	0		3	2	Ewes and second quality	3	4 3 8
Calves	4	0		5	0	Pigs	3	8 4 0

Beasts, 2043; Sheep, 22,600; Calves, 58; Pigs, 347.

Our trade to-day exhibits the characteristic dulness of the commencement of Lent. The supply continues short, particularly of Beef, in which article there seemed to be rather a brisk trade in the early part of the day; but there was much difficulty in supporting our highest quotations, and 4s 10d per 8lbs. was the more general price for the very best qualities, and 3s 6d for 8lbs. for the best Short-horns. Mutton is a much heavier sale than of late; the quantity is rather larger, the demand less, owing to the large consumption of fish at this period of the year, and the skins are a little lower. Many of our best Downs made no more than 4s 6d, and the best last description even less than that; the more general price, too, for Long-wools would be 4s per 8lbs., although in both cases some of the most selling realised our highest quotations. In Calves the trade is steady; there is a short supply of the best quality.

Friday, Feb. 23.

As regards prices our trade to-day is a counterpart of Monday's. There is a very slack attendance of buyers, and short as the supply is, there will be a difficulty in making a clearance. There is, perhaps, a slight improvement in the sale of very best Calves—that description being scarce, they readily make 4s per 8lbs.

Beasts, 800; Sheep, 2000; Calves, 98; Pigs, 267.

At, West Smithfield.

POTATOES.—Southwark Waterside, Feb. 19.

Since our last Report the weather has changed from cold and frosty to a spring-like mildness, which in some measure arrested the anticipated improvement; notwithstanding, there was an increased demand for the best samples (Devonshire Reds excepted), and the middling and inferior sorts have been more looked after. Our last quotations have been well supported. The supply during the past week has been moderate.

COVENT GARDEN, Feb. 23.—Notwithstanding the very changeable state of the weather during the week the Market has been pretty well supplied; but trade is not brisk. Fine Apples are more plentiful and are a little reduced in price. Grapes continue to bring nearly the same prices as last week. Good Pears are becoming scarce; a few good specimens of Easter Beurré, and Beurré Rance, are however to be met with in the Market. English grown Apples are scarce; but foreign ones are sufficient for the demand. Oranges and Lemons are very plentiful and good in quality. Chesnuts are offered at nearly the same prices as last week. The supply of most kinds of Vegetables is sufficient to meet the demand. Savoys are plentiful, and are at little reduced in price, being offered at from 9*d.* to 1*s.* 6*d.* per dozen. Brussels Sprouts are sufficient for the demand, as are also Greens; the latter are offered at from 3*s.* to 4*s.* 6*d.* per dozen. Carrots and Turnips are tolerably well supplied, the latter in particular. Broccoli has become very scarce. French Beans are much the same as in our last report. Asparagus is a little reduced in price, as is likewise Seakale; the latter is selling at from 1*s.* to 1*s.* 6*d.* per punnet. Little alteration has taken place in the price of Celery, which is becoming scarce. Endive is selling at from 1*s.* 6*d.* to 2*s.* per score. A small quantity of Spring Radishes has been brought to the market during the week. Cucumbers are a little reduced in price since our last report. Horse Radish is sufficient for the demand. Among Cut Flowers we noticed Combretum purpureum, Euphorbia jacquiniflora, Bauhellia capensis, Æschinanthus grandiflorus, Epiphyllum truncatum, Lachenalia triobior, Cinerarias, Azaleas, Acacias, Camellias, Tulips, Primulas, and Roses.

WOOL.—British, Friday, Feb. 23.

In our English Wool Market we have observed no material alteration from our last Report. Things continue quiet, and consumers of opinion that they are rather flatter. Prices have not at all receded, nor do we think they are likely to do so.

MARK LANE, Friday, February 23.—The arrivals of Wheat during the week have been small, and the few parcels of English fresh up this morning realised fully Monday's quotations; business in free Foreign is limited, but holders are very firm; we have not heard of any sales of Bonded, but several parcels of Baltic for Spring shipment have been taken on fully as good terms.—In Barley, Beans, and Peas there is no alteration.—Oats are held firmly, excepting where vessels are on demurrage, in which case rather lower prices are obliged to be accepted.

RENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance, can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of Iron will be found cheaper than of any other material. MR. RENDLE, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

J. WEEKS & Co., ARCHITECTS, HORTICULTURAL BUILDERS, and HOT-WATER APPARATUS MANUFACTURERS, Gloucester-place, King's-road, Chelsea.

COTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c. &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL-ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices, in consequence of the present depressed state of the Iron Trade.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public, or Private Buildings, &c., with COTTAM'S PATENT, or ROGERS' BOILERS. After 15 years' experience, and having fixed upwards of 1500 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale. For the convenience of those who wish to fix their own Apparatus, they have affixed the following low prices:—

	£	s.	d.
Cottam's Patent Boiler, 18 inch . . .	2	15	0
Rogers' Boiler, small size . . .	1	17	0

Larger in proportion.

Hot-water Pipe, at 2, 3, and 4 inches, at reduced prices.

GARDEN ROLLERS 18 inches long, 34s.; 20, 44s.; 22, 50s.; 26 inches, 60s.; 26, 75s.; 29, 84s.; 30, 105s. each.

CAST-IRON RICK-STANDS, 2 feet six inches high, 5s. 9d. each.

Garden Engines, Mowing Machines, Garden Chairs, Superior Garden Tools of all kinds, Garden Vases and Pedestals in great variety, and every description of Horticultural Articles, Agricultural Implements, and Furnishing Ironmongery; Dr. Arnott's Stoves, Anglo-Belgian Cooking Stoves; Broiling Stoves. The above low prices being on account of the depression in the Iron Trade, are subject to future alterations.

STRONG IRON HURDLES, 3 ft. high out of the ground, 6 ft. long, with five horizontal bars, weighing about 36 lbs., 3s. 6d. each.

Light Cattle Hurdles, 3 ft. 6 in. high, weighing	42 lbs.	4	0 "
Strong do. do.	45 lbs.	4	4 "
Ox Hurdles, 4 feet high, do.	60 lbs.	5	6 "

BEST WIRE, for STRAINED WIRE FENCING, at 9s. per bundle of 150 yards each. Uprights for ditto, 7d. each. The Improved continued, and every kind of Fencing, Fancy Wirework.

HAND-GLASS FRAMES for Cucumbers, &c., 18 inches square, 3s. 6d.; 20 inches, 4s. 6d.; 22 inches, 5s. 6d. each.

CAST-IRON FLOWER-STAKES, 4 ft. long out of the ground, 7s.; 4 ft. 6, 9s.; 5 ft., 11s.; 6 ft., 15s.; 7 ft., 20s. per dozen.

SHOW-ROOMS at the Manufactory, No. 2, WINSLEY-STREET, where every information may be obtained.

The TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, among other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Heat Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Greenhouses or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

CONICAL HOT-WATER BOILERS, invented by J. ROGERS, Esq., may be obtained of any size from JOHN SHEWEN, Ironmonger, &c., Sevenoaks, Kent.

J. SHEWEN having had every opportunity afforded him by an extensive practice to bring this apparatus to perfection, begs to offer it as most efficient and economical: it may be seen at Messrs. Chandler & Sons' Nursery, Vauxhall; Messrs. Loddiges', Hackney; Messrs. Henderson's, Pine Apple-place; Messrs. Veitch and Son's, Exeter; Mr. Pontey's, Plymouth; the Royal Botanical Society's Gardens, Regent's Park; and at the Gardens of the Horticultural Society of London. Considerable improvements have been effected since last season; particulars of which are in course of preparation.

BURBIDGE AND HEALY beg respectfully to inform the Horticultural world that they are quite ready to supply their new BOILER, of every size. They have now fixed a sufficient number to warrant them in stating that what they put forth as the qualities of their Boiler and Furnace arrangement may be perfectly relied upon: they have put up one at the Horticultural Gardens, where B. and H. believe it is considered to answer as represented; they have also fixed it in connection with a new description of Iron Tank, which combines the qualities of the round pipe and the open tank, which may be pronounced the perfection of a Heating Apparatus for Horticultural purposes, particularly for Graperies, Epiphyte-houses, Melonpits, &c., &c. The arrangement is such that any gentleman or gardener may have the whole constructed so as to be put together with the greatest facility by the gardener, first sending a correct plan to 130, Fleet-street. A Prospectus may be had detailing the prices, &.

GUANO, PERUVIAN, &c.—The above Manures, also Potter's Guano, Nitrates of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.

Lists of Prices, with synopsis of mode of use, on applications to MARK FOTHERGILL, 40, Upper Thames-street, and 5, Railway Place, Mark-lane, London.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing a more rapid vegetation in Plants than any substance known. It may be had at Mr. LAWES' Factory, Deptford Creek, price 7s. per cwt.

Phosphate of Potash . . .	15s.	per cwt.
" Soda . . .	12s.	"
" Magnesia . . .	9s.	"
" Ammonia . . .	1s.	per lb.

YORKSHIRE LAND-DRAINING ASSOCIATION.—Capital 500,000*l.*, in Stock of 25*l.*—Deposit, Five per Cent.

PATRONS.—The Right Hon. Lord Viscount Morpeth. The Right Hon. Lord Beaumont. Sir William M. Milner, Bart. Edward Stillingfleet Cayley, Esq., M.P.

R. M. Jaques, Esq., Easby Abbey, Richmond
James Smith, Esq. (Deanston), 8, Whitehall-place, London
Mr. William Tuke, Bradford.

With power to add to their number.

Bankers.—The York City and County Banking Company.
Standing Counsel.—H. Bellenden Ker, Esq., Lincoln's Inn.
Solicitors.—Messrs. Blanchard, Richardson, and Gutch, York.
Draining Engineer.—James Smith, Esq. (Deanston).
Secretary.—John H. Charnock, Esq., Wakefield.

The object of the present undertaking is to avail itself of the provisions of this Act, so far as they apply, and by offering an ample and easily-accessible capital, to induce the parties contemplated therein to seek the benefit of its provisions; and, at the same time to afford to the Agricultural Interest generally, on equitable terms, and on the same principle as that on which the act proceeds, the requisite means for thoroughly draining the land.

The Capital to be 500,000*l.*, in stock of 25*l.*, with a deposit of 5 per cent. on its allotment; the amount and time of the calls to be regulated by the demand, as it arises, for the beneficial employment of the money, and so that no one call exceeds 20 per cent., with a notice of not less than two months for each payment.

The management to be under an effective Committee, elected by and from the Subscribers, with the most efficient Staff that can be selected for practical and scientific skill in their several departments.

The head office to be in York, with Agencies in other towns of the county and elsewhere, as the demand for the assistance of the Association may require, and as it may be found advantageous to extend the sphere of its action.

The Meetings of the Committee of Management to be held Monthly, or oftener if necessary, and of the General Subscribers Annually, to receive the Report of the Committee, pass the Accounts, and transact other general business.

Interest after such a rate as the Committee of Management may see reason to recommend, to be allowed half-yearly on the Capital paid up, so soon as the returns on the money expended will permit; together with such further division of profits as, on a General Settlement to be made every four years, the affairs of the Undertaking will justify.

The Accounts to be balanced annually, prior to the General Meeting, and audited by competent parties duly elected.

At a meeting of the Council of the YORKSHIRE AGRICULTURAL SOCIETY, held in York on the 20th of December, 1843, a resolution was passed approving generally of the objects of this Association; and at the monthly meeting of the Wakefield Farmers' Club, held on Jan 5, 1844, a resolution approving of the principle and objects of the Association was unanimously adopted.

At the meeting of the Royal Agricultural Society of England, at Liverpool in July, 1841, Lord Stanley remarked that, "There was no bank in the whole country—no commercial speculation—no investment so safe, so pure and profitable, as that in which even borrowed capital may be engaged, by investing it under the ground of your own soil." And in reference to this Association, his Lordship in a letter to the Committee says—"I am fully satisfied of the benefits which such an Association is capable of conferring on the country if confined to its legitimate object—the lending of Capital on the security of an investment in draining; and I think it very probable that many Landed Proprietors would avail themselves of the facilities afforded by an Institution lending money on land, repayable by instalments—a condition on which few private parties are willing to lend."

Bearing in mind, then, the important objects of the Association, and the perfect security with which its operations can be conducted, at a comparatively trifling expense (no large expenditure for previous outfit being required), it may be reasonably expected that the return of the Capital embarked will be such as to insure the support of prudent and *permanent* Investors, thereby divesting it of that speculative character which has stigmatised so many modern projects, and which it is the especial desire of the Committee to avoid.

Applications for Prospectuses, &c., to be addressed to the Solicitors, Messrs. BLANCHARD, RICHARDSON, and GUTCH, York; or, to J. H. CHARNOCK, Esq., the Secretary, Wakefield.

GENUINE PERUVIAN & BOLIVIAN GUANO ON SALE, BY THE IMPORTERS, ANTONY GIBBS AND SONS, LONDON; GIBBS, BRIGHT, AND CO., LIVERPOOL AND BRISTOL.
47, Lime-st., Jan. 31. 1844.

ON SALE, in any quantity, PERUVIAN and BOLIVIAN GUANO, genuine as imported.—Apply to CORRYWORTH, POWELL, and PRYOR, London; EDWARDS, DAWSON, and Co., Liverpool; or WILLIAM J. MYERS and Co., Liverpool, the Importers.

MANURE FOR GRASS, &c.—POTTER'S GUANO.
Testimonial of Lord Zetland, Dec. 2, 1843.

POTTER'S GUANO, 2 cwt. per acre, yielded of *Hay*	2 tons	8 cwt.
Peruvian Guano, 2 cwt. per acre, yielded of *Hay*	1 "	18 "
Difference in favour of Potter's Guano		10 cwt.

BEAUTIFUL FLOWERS. — POTTER'S CONCENTRATED LIQUID GUANO, in quart bottles, 1s. 9d. each, at the principal Chemists and Seedsmen in town and country.

"I used POTTER'S GUANO on my Pansies; they were *much larger* than I ever had them before, and remained in full blow longer than I ever recollect. JOHN RUTSON, Sunderland."

"POTTER'S GUANO will convert your desert into a paradise."—Professor LINDLEY, in *Gardeners' Chronicle*, 1843, p. 660.

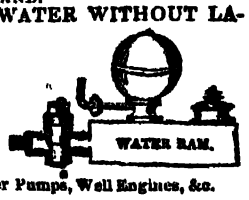
Works, 28, Upper Fore-street, Lambeth.

For further testimonials see this Paper of the 6th Jan., 1844.

GLASS SUPERSEDED for HORTICULTURAL PURPOSES by WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, rendering Muslin, Calico, or Linen, for the Frames of Greenhouses, Pine, Melon, or Cucumber Stoves, &c., impervious to rain or moisture, admitting light equal to Glass, much warmer, and the plants never burn under it.

Noblemen, Gentlemen, and Gardeners will, by using this composition have the only effectual protection for their Fruit-trees during the blooming season; it is a certain defence from frost, sleet, wind, and blight; its transparency admits the general beams of the sun, with abundance of light, which causes the bloom to expand with increased luxuriance, the fruit to set and swell more freely, much earlier, and a crop of fruit to any extent may be warranted. The covering not to be moved by day (except to thin the Fruit, which will be necessary), till the month of June. It is recommended that the Calico be prepared early, so as to be thoroughly dry before using.

Sold in Bottles, with directions for use, pints, 2s. 6d., quarts, 4s. 6d. each. One pint is sufficient to coat four Frames twice over, each Frame to be 3ft. by 3ft. 3in., or thereabouts. Prepared by GEORGE WHITNEY, Chemist, Shrewsbury. Seedsmen, Florists, and Merchants supplied by Mr. W. BAILEY, Chemist, North-street, Wolverhampton. Appointed Agents:—Messrs. BUTLER and MUCKLEY, Covent Garden, where a sample of prepared calico may be seen; Mr. WATKINSON, Market-place, Manchester; PAGE and SON, Southampton; T. and C. WHALLEY, Nurserymen, Liverpool.



Agents wanted for London and the country.

THE URATE of the LONDON MANURE COMPANY, 5*l.* per Ton. It is with the greatest satisfaction, after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By promoting a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops. The Urate may be sown broadcast, or which is preferable, by the drill, at the rate of one ton to three acres, and it is desirable it should not be placed more than two inches below the surface. As a top-dressing for Wheat the Urate has been used with great advantage. Gardeners and Florists will find it very useful for Dahlias and other roots. Full particulars and Testimonials will be forwarded on application. Genuine Peruvian Guano; Phosphate and Sulphate of Ammonia; Gypsum and every other artificial Manure.

EDWARD PURBEN, Secretary, 40, New Bridge Street.

70, STRAND.

RAMS FOR RAISING WATER WITHOUT LABOUR, WHERE A FALL CAN BE OBTAINED,

FOUNTAINS of every description. Specimens of the Fountain to be seen at the above address.

Also a Ram fixed on the premises. F. ROE, 70, Strand, London.

Every kind of Garden and other Pumps, Well Engines, &c.

GREAT ECONOMY.—Much time and a great deal of labour will be saved by the use of the SUSSEX CHURN. ATTWOOD, WIMBLE, and WARNER, Manufacturers, Lewes. This Churn being made entirely of block tin, the necessary degree of temperature can be given to the cream, by placing it in a pan of cold or hot water, which ensures the butter coming in 10 or 12 minutes at all seasons of the year. The simplicity of its construction, and the facility with which it may be cleaned, are no inconsiderable advantages over those now in common use.

Sizes.	Nos. 00.	0.	1.	2.	3.
Churn	2½ lbs.	4 lbs.	7 lbs.	14 lbs.	28 lbs. of butter.
Price with pans complete,	16s.	20s.	25s.	33s.	40s.

Delivered, carriage paid, to any part of London.

London Agents.—BENHAM, 19, Wigmore-street, Cavendish-square; LIVERMORE, 30, Oxford-street; BAILY, 71, Gracechurch-street; WRIGHT'S Range Warehouse, near the Monument.

Export Agent.—BARNES & Co., 109, Fenchurch-street.

N.B.—To be seen at the Polytechnic, and Adelaide Gallery.

Observe.—The Improved Water Pail, 4s. and 5s. each.

PARKER'S COLLECTIONS IN POPULAR LITERATURE.

SMEATON and LIGHT-HOUSES; a Popular Biography, with an Historical Introduction and Sequel. 2s.

LINNÆUS and JUSSIEU; or, the Rise and Progress of Systematic Botany. 2s.

The DELECTABLE HISTORY of REYNARD the Fox, and of his Son Reynardine. A revised version of an old Romance. 2s.

CHRONICLES of the SEASONS; or, the Progress of the Year: being a Course of Daily Instruction and Amusement, selected from the Popular Details of the Natural History, Science, Art, Antiquities, and Biography of our Father-Land. In Four Books. Book the First, containing the Months of January, February, and March. 3s. 6d.

The USEFUL ARTS employed in the Production of CLOTHING. With numerous Illustrations. 2s. 6d.

The USEFUL ARTS employed in the Production of FOOD. With numerous Illustrations. 2s. 6d.

The WRITING-DESK and its CONTENTS, taken as a Text for the Familiar Illustration of many important Facts in Natural History and Philosophy. 2s.

The HISTORY of the INVASION of RUSSIA by Napoleon Bonaparte. 2s. 6d.

A full Prospectus of the Collections in Popular Literature, with Lists of the Works in preparation, may be had on application. The above are now published, uniformly bound in cloth, and lettered.

London:—JOHN W. PARKER, West Strand.

Lady Mary Musgrave, the Numbers	

DEATH OF MR. LOUDON.

At a Meeting of the Friends of the late Mr. Loudon, held at 21 Regent Street, for the purpose of considering the best means of extricating his Widow and Daughter from the difficulties in which they are placed by his sudden death,—

Hamp[illegible], Esquire having been called to the Chair, it was Resolved:—

1. That in the opinion of this Meeting, very great services were rendered to Horticulture by the late Mr. Loudon.—2. That the difficulties in which his family is now placed, have arisen from his zeal in the promotion of gardening, and not from personal improvidence.—3. That the Works of Mr. Loudon are themselves of sufficient value to place his family in independent circumstances, provided they can be sold; and it is the opinion of this Meeting, it is most desirable that the friends of Horticulture should exert themselves to effect that end.—4. That since many persons, who already possess Mr. Loudon's Works, are probably desirous of subscribing towards a Fund for the assistance of his family, it is desirable that, in addition, a Subscription List be opened, to which the Friends of Horticulture may be invited to contribute. 5. That a Committee be appointed to receive Subscriptions, and to act otherwise as to them may seem expedient. 6. That the following Gentlemen be requested to act as Members of such Committee, viz.:—

[illegible], Secretary of the Horticultural Society.	James Cook, Esq., Brooklands.
James Maddock, Esq., Secretary of the Royal Agri. Society.	Mr. Mearnock, Royal Botanic Garden, Regent's Park.
William Spence, Esq., Lower Seymour Street.	Mr. Charlwood, 14, Tavistock Row, Covent Garden.
His Grace the Duke of Devonshire's Chatsworth.	Mr. Henderson, Pine Apple Place, Edgeware Road.

With power to add to their number.

The Committee, earnestly endeavouring to carry into effect the foregoing resolutions, respectfully present the following, as a List of the Works of the late Mr. Loudon, the sale of which will best promote their object, viz.:—

THE ARBORETUM ET FRUTICETUM BRITANNICUM; in Eight Volumes: Four of Letterpress, illustrated by above 2100 Engravings, and Four of 8vo and 4to Plates. Price 10l. cl. lrd.

In One Volume, 8vo., with upwards of 350 Engravings, price 1l. 10s., and 3l. 5s. coloured,

REPTON'S LANDSCAPE-GARDENING: being the whole Works on Landscape-Gardening and Landscape-Architecture of the late Humphry Repton, Esq.; with a Biographical Notice, and Notes by J. C. Loudon, F. L. S., &c.

Complete in One Volume, price 2l. 10s.,

AN ENCYCLOPÆDIA OF TREES AND SHRUBS: being the Arboretum et Fruticetum Britannicum Abridged, for the Use of Nurserymen, Gardeners, and Foresters.

In One Volume, 8vo., with upwards of 300 engravings, price 16s.

THE SUBURBAN HORTICULTURIST; or, an Attempt to teach the Science of Horticulture, and the Management of the Fruit, Kitchen, and Forcing Gardens, to persons who have had no previous Knowledge or Experience in these Departments.

In One Volume, 8vo., numerous Engravings, price 20s.,

THE SUBURBAN GARDENER AND VILLA COMPANION; comprising the Choice of a Suburban or Villa Residence, or of a situation on which to form one; the Arrangement and Furnishing of the House; and the Laying-out, Planting and General Management of the Garden and Grounds; the whole adapted for grounds from One Perch to Fifty Acres and upwards in Extent; and intended for the Instruction of those who know little of Gardening and Rural Affairs.

THE GARDENER'S MAGAZINE: any Number or Volume published subsequently to 1834 may be purchased separately. The Second Series, consisting of Six Volumes, from 1835 to 1840 inclusive, for 3l. 3s. 6d.; for 1841, 1l. 7s. 6d.; for 1842, 1l. 2s.

The Committee beg to add that purchasers will confer an additional benefit by sending their orders, accompanied by an order for payment in London, or at the Post-Office, to Mrs. Loudon, Bayswater, Middlesex, or to either of the following addresses:—

Mr. Mearnock, Royal Botanic Garden, Regent's Park.	Messrs. Wrench and Sons, 39, Cornhill.
Mr. Charlwood, 14, Tavistock Row, Covent Garden.	Messrs. Drake and Bromley, 315, Oxford Street.
Mr. Henderson, Pine Apple Place, Edgeware Road.	Messrs. Minier, Adams and Nash, 63, Strand.

A List of Subscribers will be published weekly in this Paper.

Subscriptions will be received by the Treasurer, J. Cuthill, Esq., 65, Manchester Lane, London, and by the following Bankers:—Sir[illegible] and Co. Lombard Street; Sir John W. Lubbock, Bart. and Co. Stratton House Street; and Messrs. Coutts, Strand, London.

The following is a List of the present Subscriptions:

His Grace the Duke of Devonshire, President of the Horticultural Society		£20	0 0
James Cook, Esq.		20	0 0
Robert Mitford, Esq., 44, Porchester Terrace		1	1 0
J. M. Blankfield, Esq.		5	5 0
Joseph Paxton, Esq.		10	0 0
Sir John W. Lubbock, Bart.		10	0 0
Messrs. Loddiges and Sons		20	0 0

Letters and Communications addressed to the House, 21, Regent Street, under cover to Mr. Drake, will receive immediate attention.

FOR [illegible]

THE ZOOLOGY [illegible]
Natural History, [illegible]
Fishes, Clifford [illegible]
Esq., Secretary [illegible]
Sketches of the [illegible]
of the Cabbage Butterfly [illegible]
John Van [illegible] 2l. [illegible] cloth

LECTURE ON THE [illegible] containing its Natural History [illegible] management; and how to obtain pure [illegible] through the Nose.

By G. L. A. Lloyd.

Sold by Hamilton and Co., Paternoster-row. Price 3d.

An excellent work to distribute among the Poor.

The following Periodical Works, for March 1844, will be published by CHARLES KNIGHT & Co.

OLD ENGLAND, Part IV., with a coloured Engraving. Price 1s. 6d. Published also in Weekly Numbers, at 2d.; with the Coloured Engraving as a Supplementary Number, price 6d.

THE PICTORIAL SUNDAY BOOK, Part III., with a Coloured Map, price 1s. 6d. Published also in Weekly Numbers at 2d.; with the Coloured Map, and a sheet of Letter-press descriptive of the Geography of the Holy Land, as a Supplementary Number, price 6d.

THE PENNY MAGAZINE, Part XXXVIII. of the New Series, price 6.

THE PICTORIAL HISTORY OF ENGLAND during the Reign of George III., Part XXXVIII., super-royal, 8vo., price 2s., completing the Work.

LONDON, Part XXXVI., price 1s. 6d., completing the Work. Published also in Weekly Numbers, price 4d.

THE PICTORIAL MUSEUM OF ANIMATED NATURE, Part. XV., price 1s. Published also in Weekly Numbers, price 3d.

THE LIBRARY FOR THE TIMES. Monthly Series. OUR INDIAN EMPIRE. By C. MacFarlane. Vol. I., price 2s. 6d., sewed; or, 3s. 6d. bound in cloth.

RE-ISSUE IN MONTHLY VOLUMES, OR SECTIONS OF COMPLETED WORKS.

On the 1st January 1844, these Works commenced to be re-issued in Monthly Volumes, or Sections, so as to enable new Subscribers, with a very moderate Periodical Outlay, to become possessed, within a short period, of Books which are universally acknowledged to be the best foundation of a private Library. All doubts of their proper completion, which too often apply to large Periodical Works, are now set at rest.

The Monthly Re-issue will be as follows, all the Volumes or Sections being strongly and elegantly sewed in a novel style:—

THE PENNY CYCLOPÆDIA. A Monthly Volume, at Six Shillings, completed, in 27 Volumes, in March 1846.

THE PENNY MAGAZINE, 1st Series. A Monthly Volume, at Four Shillings. Completed in 9 Volumes, in October 1844.

THE PICTORIAL BIBLE, and the HISTORY OF THE JEWS (including the Natural History of the Holy Land). A Monthly Section, including a portion of each Work, at Six Shillings. Completed in 13 Monthly Parts, in December 1844.

THE PICTORIAL EDITION OF SHAKSPERE, including the Biography. A Monthly Section at Six Shillings. Completed in 21 Monthly Parts, in September 1845.

The PICTORIAL HISTORY OF ENGLAND, to the conclusion of the Reign of George II. A Monthly Section at Six Shillings. Completed in 15 Monthly Parts, in March 1848.

THE PICTORIAL HISTORY OF ENGLAND during the Reign of George III. A Monthly Section at Six Shillings. Completed in 12 Monthly Parts, in December 1844.

ALSO, THE PICTORIAL HISTORY OF ENGLAND, during the Reign of George III. Vol. IV., super-royal 8vo., in cloth boards, price 20s. This Volume completes the Work. The previous Volumes may be had, price 20s. each.

LONDON. Vol. VI., price 10s. 6d. This Volume completes the Work. Any of the preceding Volumes may still be had price 10s. 6d. each.—22, Ludgate-street, Feb. 20, 1844.

TO NOBLEMEN, AGRICULTURISTS, and OTHERS.

ANALYSES of SOILS, MANURES, &c., are conducted by Mr. Mitchell, Analytical Chemist (late of the Royal Polytechnic Institution), No. 5, Victoria Cottages Hawley-road, Kentish-town. N.B.—A Vacancy now occurs for One House or Out-door Pupil.—Apply as above.

Just Published, Price 1s.,

PRACTICAL HINTS on New and Old MANURES. By John Dondridge Humphreys, Esq., Author of the "Electro-Physiology of Man," &c., &c. With an explanation of the Author's Discovery of the Governing Principles of Vegetable Growth; and full information as to the use and superior advantages for Wheat, Barley, Turnips, &c., of the New Manure called "HUMPHREYS'S FARMERS' COMPOUND," as manufactured at 12s. per cwt. by Messrs. Davy, Mackmurdo, and Co., 100, Upper Thames-st., London.

Longman, Brown, Green, and Longmans.

NEW METHOD OF TRANSPLANTING.

This day, 8vo, with Illustrative Plate, 7s.

THE TREE-LIFTER; or, a New Method of Transplanting Trees. By Colonel Georges Greenwood. London: Longman, Brown, Green, and Longmans.

BLACK ON BREWING—THIRD EDITION.

Published this day, Third Edition, 8vo, 10s. 6d.,

A PRACTICAL TREATISE on BREWING, based on Chemical and Economical Principles; with Formulæ for Public Brewers, and Instructions for Private Families. By William Black. Third Edition, revised and corrected, with considerable Additions. The Additions revised by Professor Graham, of the London University.

London: Longman, Brown, Green, and Longmans.

Post Octavo, 5s.

PRACTICAL CHEMISTRY for FARMERS and LANDOWNERS. By Joshua Trimmer, F. G. S.

By the same Author, 8vo. with Two Hundred Illustrations, 15s.

PRACTICAL GEOLOGY and MINERALOGY, and the CHEMISTRY of METALS, with an Introductory Discourse on the Nature, Tendency, and Advantages, of Geological Pursuits.—London: John W. Parker, West Strand.

Price 6s. 6d., cloth, gilt edges,

MRS. LOUDON'S LADIES' COMPANION to the FLOWER-GARDEN. Being an Alphabetical Arrangement of all the Ornamental Plants usually grown in Gardens and Shrubberies; with full directions for their Culture.

London: Published by William Smith, 113, Fleet-street.

BOTANICAL & GARDENING WORKS

PRINTED FOR

LONGMAN, BROWN, GREEN, & LONGMANS

THE THEORY OF HORTICULTURE; or, an Attempt to explain the Principal Operations of Gardening upon Physiological Principles. By Jane Loudon, Ph.D., F.R.S. Post, Illustrations on Wood. 12s. cloth.

INTRODUCTION TO BOTANY. By Professor J. Lindley, Ph.D., F.R.S. Third Edition, with Corrections and considerable Additions. 8vo. 20s. Plates and numerous Woodcuts, 30s.

A NATURAL SYSTEM OF BOTANY; or, a Systematic View of the Organization, Natural Affinities, and Geographical Distribution of the whole Vegetable Kingdom; together with the uses of the most important species in Medicine, the Arts, and Rural or Domestic Economy. By John Lindley, Ph.D., F.R.S. Second Edition, with numerous Additions and Corrections, and a complete List of Genera, with their Synonyms. 8vo. 18s.

SCHOOL BOTANY; or an Explanation of the Characters and Differences of the principal Natural Classes and Orders of Plants belonging to the Flora of Europe, in the Botanical Classification of De Candolle. For the use of Students preparing for their matriculation examination in the University of London, and applicable to Botanical Study in general. By John Lindley, Ph.D., F.R.S., Fcp. 8vo., with upwards of 100 Woodcuts, 6s.

A SYNOPSIS OF THE BRITISH FLORA, arranged according to the Natural Orders. By Professor John Lindley, Ph.D., F.R.S., &c. The Third Edition, with numerous Additions, Corrections, and Improvements, 12mo. 10s. 6d.

GUIDE TO ORCHARD AND KITCHEN GARDEN; Or, an Account of the most valuable Fruits and Vegetables cultivated in Great Britain; with Kalendars of the Work required in the Orchard and Kitchen Garden during every month in the year. By George Lindley, C.M.H.S. Edited by Professor Lindley. 8vo. 16s.

AN ENCYCLOPÆDIA OF GARDENING; presenting in one systematic view, the History and Present State of Gardening in all Countries, and its Theory and Practice in Great Britain, with the Management of the Kitchen Garden, the Flower Garden, Laying out Grounds, &c. By J. C. Loudon, F.L.S., &c. New Edition, enlarged and much improved. 8vo. With nearly 1,000 Woodcuts, 2l. 10s.

AN ENCYCLOPÆDIA OF PLANTS; including all the Plants which are now found in, or have been introduced into Great Britain; giving their Natural History, accompanied by such descriptions, engraved figures, and elementary details, as may enable a beginner, who is a mere English reader, to discover the name of every Plant which he may find in flower, and acquire all information respecting it. New Edition, with a Supplement. By J. C. Loudon; W. H. Baxter, Jun.; Gordon Don, F.L.S.; and J. D. C. Sowerby, F.L.S. 1 vol. 8vo. with nearly 10,000 woodcuts, 3l. 13s. 6d.

HORTUS BRITANNICUS; a Catalogue of all the Plants indigenous to, or introduced into Britain. Third Edition, with a New Supplement, prepared, under the direction of J. C. Loudon, by W. H. Baxter, and revised by Gordon Don, F.L.S. 8vo. 31s. 6d. The First Supplement, separately, 2s. 6d., the New Supplement, separately, 3s.

THE ROSE AMATEUR'S GUIDE; containing ample Descriptions of all the fine, leading varieties of Roses, particularly cultivated in their respective families; their History, and Mode of Culture. By T. Rivers, Jun. Third Edition, corrected and improved. Fcp. 8vo. 6s.

THE TREE-LIFTER; or, a new Method of Transplanting Trees. By Colonel Georges Greenwood. 8vo. with Illustrative Plate. 7s.

A SCRIPTURE HERBAL. With upwards of 120 Wood Engravings. By Lady Calcott. Square crown 8vo. 14s. 6d.

CONVERSATIONS ON BOTANY. Ninth Edition, improved, fcp. 8vo., with 23 Plates, 7s. 6d.; with the Plates coloured, 12s.

THE PRINCIPLES OF DESCRIPTIVE AND PHYSIOLOGICAL BOTANY. By J. S. Henslow, M.A., F.L.S., &c. Fcp. 8vo. with Vignette Title, and nearly 70 Woodcuts, 6s.

A PRACTICAL TREATISE ON THE CULTIVATION OF THE GRAPE VINE ON OPEN WALLS. By Clement Hoare. Third Edition, 8vo. 7s. 6d.

AN INTRODUCTION TO THE STUDY OF BOTANY. By Sir J. E. Smith, late President of the Linnean Society. Seventh Edition (1838); corrected; in which the object of Smith's "Grammar of Botany" is combined with that of the "Introduction." By Sir William Jackson Hooker, K.H., LL.D., &c. 8vo. 36 Steel Plates, 16s.; with the Plates coloured, 2l. 12s. 6d.

THE ENGLISH FLORA. By Sir James Edward Smith, M.D., F.R.S., late President of the Linnean Society, &c. 6 vols. 8vo. 3l. 12s.

CONTENTS:

Vols. I. to IV. The Flowering Plants and the Ferns, 2l. 8s.

Vol. V. Part 1, 12s.—Cryptogamia; comprising the Mosses, Hepaticæ, Lichens, Characeæ, and Algæ. By Sir W. J. Hooker.

Vol. V. Part 2, 12s.—The Fungi—completing the work, by Sir J. W. Hooker, and the Rev. M. J. Berkeley, F.L.S., &c.

COMPENDIUM OF THE ENGLISH FLORA. By Sir J. E. Smith. Second Edition, with Additions and Corrections by Sir W. J. Hooker. 12mo. 7s. 6d.

THE SAME IN LATIN. Fifth Edition, 12mo. 7s. 6d.

THE BRITISH FLORA. In Two Vols. Vol. I., comprising Phænogamous or Flowering Plants and the Ferns. By Sir William Jackson Hooker, K.H., LL.D., F.R.A., and L.S., &c. &c. &c. Fifth Edition, with Additions and Corrections; and 173 Figures illustrative of the Umbelliferous Plants, the Compositæ Plants, the Grasses, and the Ferns. 8vo. with 12 Plates, 14s.; with the Plates coloured, 24s.

Vol. II. in Two Parts, comprising the Cryptogamia and Fungi, completing the British Flora, and forming Vol. V., Parts 1 and 2, of Smith's English Flora, 24s.

THE VEGETABLE CULTIVATOR; containing a plain and accurate Description of all the different Species of Culinary Vegetables, with the most approved Method of Cultivating them by Natural and Artificial Means, and the best Modes of Cooking them; with a Description of the Physical Habits of Esculent Use. By John Reynal, Author of "The Field Gardener." Foolscap 8vo, 7s.

LONDON: LONGMAN, BROWN, GREEN, & LONGMANS.

Printed by Messrs. McGowan and Shaw, Pemberton-buildings, Finsbury, in the Parish of St. Luke, in the City of London, and Published by them at the Office, No. 5, Gate-street, Lincoln's-inn-fields, in the County of Middlesex, where all Advertisements and Communications are to be addressed to the Editor.—Saturday, February 24, 1844.

UNRIVALLED NEW DAHLIA.—DANIEL'S "MADELINE"

CHARLES DANIELS begs to inform the trade that he has disposed of what Ground Roots he has to spare of the above splendid Dahlia; therefore, all future orders will be executed with Plants the 1st of May, at 10s 6d each. The usual discount to the trade where six Plants are taken. For description see Advertisement 9th of January.

N B.—As strict priority will be observed, early Orders are solicited to ensure good strong Plants.—Hessle-road Nursery, Hull, Feb. 27, 1844.

J. D. PARKS, Dartford Nursery, Dartford, Kent, begs leave to announce to the Trade and Public generally, that he has now ready the following Plants:—

Lagerum Intermedium, a fine variety from Seed, a luxuriant grower, racemes of flowers very long, flowers thickly set, and of a deeper yellow than the common, selling at 7s. Dr Lindley considers it a very desirable variety.

A Seedling Verbena, Fanatica, which is in the character of Incisa, much improved, selling at 2s.

A Pamphlet on THE SPINE, OR DERANGEMENT OF THE BACK, written by J. D. Parks, who has been afflicted with the same malady, who never walked for three years, very little for six years, now cured, and undertakes the cure of others; can refer parcels to a patient now under his care; the Pamphlet, 1s., can be had of the Author, or any Bookseller.

Published by Baynham, No. 11, Paternoster-row, London.

All the above can be had of Messrs Rusby and Co., Seedsmen, &c., Leadenhall street.

N.B.—The Pamphlet can be sent under a 2d. stamp.

EUCHARIDIUM GRANDIFLORUM—A SPLENDID NEW HARDY ANNUAL.

WILLIAM MAY begs to offer the above new and beautiful Annual for the first time, seeds of which were kindly presented to him in 1843 by Capt. Widdrington, R.N., who introduced it from the Royal Botanic Garden of St Petersburg. It is twice the size of E. coloratum, of a brilliant dark rosy red, and very appropriate for pegging or beds, blooming most part of the summer, and is decidedly one of the best of annuals in cultivation. May be had in packets, at 2s. 6d. each, Post paid.

William May, Hope Nursery, Leeming lane, Bedale, Yorkshire.

CROSS LANES NURSERY, near BEDALE, YORKSHIRE

W. JACKSON and Co., in returning their sincere thanks to the Nobility, Gentry, and Public for their liberal patronage, beg to announce that they can still supply the following of first-rate quality, which will be forwarded with the utmost despatch to any part of the kingdom. Delivery at the railway guaranteed.

100 select showy Herbaceous Plants, in 50 named sorts, for 25s.
100 Dwarf Roses, in 50 named sorts, for 20s.
100 Do in 100 named, very fine sorts, for 60s.
100 Do. in 100 do., extra fine sorts for 75s.
50 Standard Roses, in 50 splendid varieties, including the fine Hybrid Perpetuals, for 20s.

A Large Stock of fine transplanted English Oaks of all sizes.

Catalogues may be had on application, inclosing two postage stamps. A remittance or reference from unknown correspondents is respectfully solicited.—Feb 29, 1844

NEW AND SUPERB COLLECTION OF SEEDLING FUCHSIAS.

W. J. EPPS begs to announce that his Superb Collection of Seedling Fuchsias are now ready to be forwarded per post, free, packed in tin cases, upon receipt of a post-office order or a reference. For description and price see last week's Chronicle.—W. J. E. will not be able to execute any more orders for Rhododendron, Wilsonii, and Emperor of China, before the latter end of the month.—Bower, Nursery, Maidstone, March 1, 1844.

RANUNCULUSES, ANEMONES, PELARGONIUMS, AURICULAS, CARNATIONS, AND LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by Appointment Florist to Her Majesty, begs to inform the Nobility, Gentry, and Amateurs, that, in consequence of the success he has had in the cultivation of the above flowers at his new Garden, he can offer them at very moderate prices. He would particularly recommend an early application to be made for RANUNCULUSES, both ANEMONES, as they should not be planted later than the end of March to obtain a good bloom. His Catalogue of PELARGONIUMS, RANUNCULUSES, and NEW PLANTS, is now ready, and will be forwarded by post on application. The Trade supplied.

WILLIAM MASTERS begs to call the attention of the Nobility, Gentry, &c., to his newly and well assorted COLLECTION OF GARDEN AND FLOWER SEEDS, which being principally grown under his immediate inspection, he can particularly recommend

Wm Miller, Providence Nursery, Ramsgate Feb 27, 1844

DANE CROFT NURSERY, BOWMARKET SUFFOLK

SAMUEL GIRLING, English and Foreign Dahlia Agent submits the following choice SEEDLING DAHLIAS to his numerous friends for 1844, plants of which can be had early in May, they are all faithfully described, and early orders are respectfully solicited as the stock of some of them is very limited. General Catalogues of DAHLIAS, GERANIUMS, PANSIES, FUCHSIAS, and VERBENAS, can shortly be had, on prepaid application

Beauty of Suffolk (Brake's) —Bronzy purple, of superior form and excellent habit a constant and extra second rate show flower; seedling prizes at Ipswich and Stowmarket Height 4 feet —Price 7s 6d

Bermondsey Rose (Proctor's) —A crimson purple, of excellent form and fine general habit, well capped stiff petals, when well grown one of the best self Dahlias in cultivation —4 ft —10s 6d

Modfi (Bourn's) —Dark purple, of first rate form, has taken first prizes at the Metropolitan and other shows, and pronounced a first class flower 4 ft —10s 6d

Nonpareil (Proctor's —Ruby scarlet of first rate form, habit excellent, free bloomer, pronounced by the Horticultural Society of London and at the Slough exhibition to be a first-class flower The stock of this beautiful Dahlia is small, and unless it breaks well will be held in another year No allowance on this variety unless six plants are ordered Glenny's opinion of this Dahlia is, that well grown it will be a trimmer 4 ft —10s 6d

Orange Perfection (Bolan's) Of good form and habit, an extra second rate show flower rather low in the centre, but sometimes well up, when it will beat all the orange class 4 to 5 ft —7s 6d

Red Rover (Girling's) —Of good general properties and extra fine habit; colour fine red, and useful for showing 4 to 5 ft —7s 6d

Talma (Girling's) —Purplish rose of superior form and habit, little short of first rate, rising centre and very constant, 4 ft —7s 6d

Sir John Stewart Richardson (Union, in which S G has a share), which is one of the most popular Dahlias of the season No allowance on this variety unless 12 plants are ordered 4 ft.—10s. 6d

FANCY DAHLIAS

Cornelia (Girling's —Purple, tipped with white, of good habit and very distinct. 4 ft —5s

Garland (Girling's) —With three colours—cream, sulphur, and brown tip, of good form and habit 5 ft.—5s

Madame Miellez (Girling's —Rose lilac, tipped or striped with white, a distinct variety, of good habit. 3 to 4 ft —5s

Madame de Berghe (Girling's) —White edged with pink; a distinct and beautiful variety 3 ft.—5s.

Madame Chauvierre (Girling's).—Light crimson tipped with pure white, very constant, good shape, and one of the finest border Dahlias in cultivation. 4 ft —5s.

Village Maid (Girling's).—Colours white and purple, distinctly and beautifully tipped; good habit, and superior border variety. 3 to 4 ft —5s.—Stowmarket, Feb. 29, 1844.

GAINES'S NEW AND FIRST-RATE PELARGONIUMS now ready for delivery, in strong, healthy Plants. The following are a few selected.—Golden's Elegans nova, King of Beauties, Ackbar, Lady Prudhoe, Queen King, Exodus, Beauty Supreme, Mogul, Edith, Comicide of Retined, Catharstive, Egbert. A list of Pelargoniums, Fuchsias, Calceolarias, Fuchsias, Verbenas, Auriculas, Cinerarias, Chrysanthemums, Dahlias, &c., which contains many new Seedlings of first-rate qualities, plants ready, 10s. 6d.; also a few roots of the Seedling Dahlias Prince and Alice and Twickenham Fairy, are still to be disposed of at the Nursery, Surrey-lane, Battersea.

JOHN MILLER, surviving Partner of the late firm of Sweets and Miller, Nursery and Seedsmen, Bristol, begs respectfully to inform Nurserymen, the Trade, and his Friends in general, that he has commenced business as Auctioneer and Valuer of Horticultural and Agricultural Stock, &c., and hopes by strict attention to the interest of his employers, to merit their support. Letters addressed to John Miller, Portland House, Kingsdown, Bristol, will meet with immediate attention.—Bristol, February 29 1844

WILLIAM MASTERS begs most respectfully to inform the Nobility and Gentry of the United Kingdom that he unites the Professions of LANDSCAPE-GARDENER and NURSERYMAN, and this enables him to offer an extensive Collection of Coniferous Plants, as well as of the Hardy Ornamental Trees and Shrubs cultivated in Britain, at very moderate prices.

W. M also possesses a numerous Assortment of Mexicans and Greenhouse Plants, many of the rarer species of Orchidaceæ, several new hybrid Crinums, Rhododendrons, Azaleas, Indias, Camellias, Succulents, Pelargoniums, &c. &c.—Exotic Nursery, Canterbury, Feb 1844

SLOUGH NURSERY, NEAR WINDSOR.

CHOICE SELECTION OF NEW DAHLIAS, 1844.

THOMAS BROWN directs attention to his beautiful SEEDLINGS, particularly that unrivalled light flower, "Lady Ann Maun," the superiority of which over every other of its class is too well known to need further comment. Strong and healthy plants will be ready for delivery early in May.

Aurantia (Sparry's)—Orange buff; fine form and petal. A very desirable show flower; obtained numerous prizes, 3 ft 10s 6d

Alexandre (Brown's)—Maroon and crimson mottled; full and constant, centre well up, and a very useful show flower; 5 ft. 7 6

Deficient (Brown's)—Cream, veined and tipped with purple petal of fine substance and high quality, very distinct to any in cultivation; 4 ft. 2, 6

Desirable (Brown's)—Shaded buff, quite new in colour; a good show flower; 5 ft. 7 6

Lady St. Maur (Brown's)—White, delicately shaded with violet purple; very deep and full, high centre, forming a beautiful outline; the petals are round, and smooth at the edge; habit of Perpetual Grand; it is decidedly the finest light flower ever offered. It attracted great admiration at Windsor, and was universally acknowledged to be the finest flower in the Exhibition; 4 to 5 ft. 10 6

Nuwits (Brown's)—Bright crimson; a fine open-capped petal, and a good show flower; 4 ft. 7 6

Raphael (Brown's)—Dark maroon, beautifully shaded with light crimson; superior petal, of excellent form; a very novel and striking variety, and will be an acquisition to any stand; 4 ft. 10 6

Rembrandt (Brown's)—Dark purple, very round and double, rising well in the centre, and a constant show flower. It was very successfully exhibited; 3 to 4 ft. . 10 6

Emma Nogs (Dowding's)—Black white, good general form and carries a good useful show flower; 4 ft. . . 12 6

Essex Bride (Turville's)—Delicate peach lilac, of excellent petal and form, 5 ft. . . . . (no discount) 10 6

Lady Antrobus (Sparry's)—White and lilac, mottled; good form, constant, and very useful show flower; 4 ft. 10 6

Nonpareil (Proctor's)—Ruby scarlet, of first-rate properties; extra show flower; 4 ft. . . . . (no discount) 10 6

Standard of Perfection (Keynes')—Crimson; of very superior form; 4 ft. . . . . (no discount) 10 6

Sir J Stewart Richardson (Union)—Brown ruby, great depth, and excellent show flower, 4 ft (no discount) 10 6

T B has also Selections of fine Carnations, Picotees, and all other Florists' Flowers, Plants, Fruit-trees, Shrubs, and general Nursery Stock

A general Catalogue of Dahlias, with a List of Superb New Pansies to be had on application.

TO THE NOBILITY, GENTRY, CLERGY, AMATEURS, AND OTHERS

THE SUBSCRIBER begs to state that he is prepared to supply the undermentioned, viz —

Cineraria, "The Queen of May,"—a beautiful sky-blue, of shrubby compact growth, quite new colour, of fine form and large size, at 5s each.

Cinerarias—12 of the most distinct and approved varieties for 20s.

Fuchsias—25 distinct fine sorts, including his own seedlings, for 20s

Calceolarias—20 distinct and good sorts, of all shades of colour, for 20s

Hollyhocks—fine strong one year old plants from his best selected seed, 20s per 100

Herbaceous Plants of the most showy varieties, correctly named, 100 sorts for 42s

Hardy, Flowering, and Evergreen Shrubs, in 50 sorts, two plants of each, correctly named according to Loudon's "Arboretum Britannicum" 12s per 100 including package.

He will also have to offer in April a new Collection of beautiful Calceolarias, and yet select of a Descriptive Catalogue of which is in preparation and will be forwarded to applicants. These are from his own celebrated Stock, and of the same breed as his Cal. "Lady Constable" so much in repute.

Seeds in packets of Hollyhock, Pansy, Picotee, Calceolaria, and Hybrid Fuchsia at 1s 6d and 2s each

TO THE TRADE, MARKET GARDENERS, AND OTHERS.

he begs to state that he has yet to offer a few thousands of Gooseberries and the large Red Antwerp Raspberries.—The Gooseberries are comprised in upwards of 100 of the most generally useful kinds in cultivation, and the Red Antwerp Raspberry is decidedly the best sort grown, for produce, size, and quality both of which he will offer on very moderate terms, in quantity The plants are young, clean, strong, and healthy, two and three years old.—Also May's new large late red "Victoria Currant," a dish of which was sent to and exhibited in 1842 at the Horticultural Society in Regent-street, London, some of the bunches of which measured 6 inches in length, and individual berries 1½ inch in circumference—15s per dozen New Black Shaw-top Currants, 5s. per doz. The usual allowance to the Trade on the Currants.

Woollen Net for protecting Fruit-trees from frost, of the best material, at 2d. per yd.

Stove and Greenhouse Plants and Florists' Flowers of every description. Forest and Fruit Trees, Garden and Flower Seeds, of all the approved sorts William May.

Hope Nursery, Leeming-lane, near Bedale, Yorkshire.

A superior collection of Pansies, comprising all the new and approved varieties, of which priced Catalogues may be had on application.

A constant supply of all the choicest kinds of Phlox, Pentstemons, Œnotheras, Delphiniums, and other favourite Herbaceous Plants will be kept during March and April.

Orders taken for Miller's splendid New Verbenas and Fuchsias, Plates of which may be seen in "Paxton's Magazine" for February and March, or at No. 6, Leadenhall street.

Metallic Wire and Labels, Garden Tools, Knives, &c. &c.

Agents for the sale of Humphrey's Compound.

Wholesale and Retail Seed Establishment, 6, Leadenhall-street;—Warehouse, 19, Vine-street, Minories.

SEED-TRADE—NO MONOPOLY.

J. G. WAITE, 1 and 4, Eyre-street-hill, Hatton-Garden, London, most respectfully begs to acknowledge the handsome support he has received from all parts of the country since his Advertisement in the *Chronicle* of last Saturday, and assures all those who may favour him with Orders that he will continue to pursue the system he has adopted in supplying Genuine Articles at the smallest remunerating profits, without heeding the opposition of Monopolists, or the clamour of parties interested in keeping up high prices.

J. G. W. refers his Lancashire friends to his CATALOGUE OF SEEDS, advertised in the *Preston Guardian* of this day.—March 2nd, 1844.

PASTURE AND LAWN GRASSES of the Finest

Quality, selected for every description of soil, consisting of Poas, Fescues, Cold Grass, Meadow Foxtail, &c., with a moderate supply of Clover, will enable Noblemen and Gentlemen to lay down upon very reasonable terms. Particulars of quantities suitable to various soils to be had, with an estimate of the cost per acre, by application to WARNER and WARNER, Seed-merchants, 28, Cornhill, London. Genuine Italian Rye-Grass, Mangold Wurtzel, and superior selected Turnip-Seeds.

PERENNIAL GRASS SEEDS.

SUTTON AND SONS, having for many years paid particular attention to the collecting of NATURAL GRASSES, and having been employed by most of the Nobility and Gentry of Berkshire, Hampshire, and Oxfordshire, to mix Seeds in proper sorts and proportions to suit the soils on their Estates, both for laying down new Pastures and improving old ones, have great confidence in soliciting orders from the readers of the *Gardeners' Chronicle*, in the more northern parts of the kingdom.

SUTTON and SONS have just published a Descriptive Table of Grasses, with some information which they consider would be acceptable to their Agricultural friends, and which may be had gratis.—The cost of the Seeds is very moderate, as will be seen by a reference to the Table above referred to.

Agents for Potter's Guano.

Reading Seed Warehouse, 7 and 8, Market-pl., Reading, Berks.

Ditto equally choice in 30 Sorts . 0 12 6

Messrs. SUTTON and SONS growing almost every kind of Flower-Seed worthy of recommendation, are enabled to supply their customers with such New Seeds as will not cause the disappointment so often experienced in attempting to produce a constant supply of bloom in the Flower Borders.

N.B. Parcels delivered free to London or sent free by Post.

Agents for Potter's Guano & Whitney's transparent Composition.

Reading Seed Warehouse, 7 and 8, Market-pl., Reading, Berks.

SEEDS.—Belgium Large White Carrot, 1s. per lb.; Mangold Wurtzel, Long Red, Orange Globe, and Red Globe, 1s. per lb. each; Le Couteur's Belle Vue Talavera Wheat, 11s. per bushel; Kintbury Skiuless Barley, 8s. 6d. per bushel; Meadow and Pasture Grass Seeds in Mixtures, suited to soils, &c., at 32s. per acre; Mixed Sorts for improving old Grass Land, 1s. 3d. per lb.; Fine Sorts for forming Lawns, &c., 1s. 4d. per lb. Price Catalogues of Turnips and other Seeds are ready. Kitchen Garden and Flower Seeds.—GEORGE GIBBS AND CO., Seedsmen, &c. to the Agri. Soc., 26, Down-street, Piccadilly.

SHILLING'S EARLY GROTTO PEA.

J. AND S. SHILLING have succeeded in raising the above PEA, the Early Frame Pea, impregnated with the Grotto or Oyster Marrow, which they, with confidence, recommend to the Public generally, being quite as early, and nearly double the size of any other Pea in cultivation. Quite hardy, will stand the winter well, and a good bearer; the pod large and long. They would particularly recommend it to the attention of Market Gardeners. Price 3s. per quart; 10s. per gallon; 17s. 6d. per peck; 30s. per half-bushel; 2l. 10s. per bushel. Agents:—Messrs. FIELD and CHILD, 119, Lower Thames-street, London; Messrs. W. and J. NOBLE, 123, Fleet-street; Mr. KERNAN, 4, Great Russell-street, Covent Garden; Messrs. HURST and MCMULLEN, 61, Leadenhall-street; Messrs. GRAY, ADAMS, and BOND, Kensington; Mr. T. D. WATKINSON, Market-place, Manchester.—Northwarnborough Nursery, near Odiham, Hants.

THE BRITISH QUEEN AND PRINCE ALBERT PEAS.

WM. JNO. CORMACK begs to call the attention of Noblemen, Gentlemen, and others, to the above two new Varieties, the merits of which are thus noticed in the *Gardeners' Chronicle*. "THE BRITISH QUEEN on light soils, is the best of all kinds, and will drive Knight's Tall Marrow out of the gardens." "THE PRINCE ALBERT, which has been cultivated in the Garden of the Horticultural Society during the season, produced Peas fit for the table *ten days earlier* than any other variety sown at the same time." Both varieties may be had in packages at 2s. 6d. each, at W. J. C.'s wholesale Establishment, Newcross, or the Bedford Conservatory, Covent Garden.

A CATALOGUE OF CHOICE DAHLIAS, raised by

W. R. WHALE, Florist, &c. &c., Rose, near Kingsclere, Berks.

Blue Bonnet, brown, self
Colonel Baker (Dodd's), self
Confidine (Cook's), orange
Cornett (Thomson's), dark, self
Dreadnaught, self
Essex Triumph, dark, self
Favourite (Dodd's), light-edged purple
Hero of Stonehenge (Whale's), dark-mulberry
King of the West (Walters's), dark, self
Miranda (Brown's), white-mottled purple
Mrs. J. Richardson (Edwards's), white and purple
Mogul Atwell, self
Paul Pry (Brown's), rose
Perpetual Grand (Brown's), red
Purple Perfection (Mitchell's)
Ashmodeus Rival (Compton's), mottled-rose
Sir R. Sale, self
Sultana (Appleby's), shaded purple
Vivid (Thomson's), scarlet
Virgil, dark, self
Perfection (Keynes's), purple
Venus (Gaine's)
Venus (Atwell's), white
Suffolk Hero, dark, fine
King of Lilacs (Girling's)
Claude Laurain (Harrison's)
Lady of the Manor (Atwell's), light-edged purple
Lady of the Lake (Gaine's)
Sir R. Chester (Stein's), dark, self
Litchfiel, scarlet, large flower
Lady Sale (Edwards's), red
Victory of Sussex (Standford's), dark, fine
Novelty (Whale's), shaded red
Queen of Trumps (Brown's), &c.

The following Good Old Varieties, at 12s. per Dozen.

Admiral Stopford
Andrew Hofer
Admirable
President of the West (Whale's)
Phenomenon, ditto
Attila, ditto
Beauty of the Plain (Spary's)
Mrs. Shelly
Lady Cooper
Maria (Wheeler's)
Competitor (Hodges')
Grand Baudese (Low's)
Conservative, ditto
Bedford Surprise
Lady Murray
Euclid (Ward's)
Eclipse, W.
Eclipse, C.
Tournament, C.
Indispensable, G.
Burnham Hero
Bridesmaid
Maid of Bath
Candidate (Silverlock's)
Duchess Richmond
Lady Harland
Marquis Lansdowne
Metella (Brown's)
Marchioness Exeter
Prince of Wales, D.
Prince of Wales, G.
Pickwick
Princess Royal, H.
Queen, W.
Rival Sussex
Rouge-et-Noir
Sir F. Johnstone
Springfield Rival
Twyford Perfection
Prince Albert, A.
Defiance (Cox's)
Rose Unique (Ansell's), &c. &c. &c.

Robespierre, dark plum-colour, 2s. 6d.

A Good Assortment of Fancy Varieties, at 12s. per Dozen.

Oakley's Surprise, Nihile, &c. &c. &c.

BURBIDGE AND HEALY

beg respectfully to inform the Horticultural world that they are quite *ready* to supply their new BOILER, of every size. They have now fixed a sufficient number to warrant them in stating that they put forth as the qualities of their Boiler and Furnace arrangement may be perfectly relied upon: they have put up one at the Horticultural Gardens, where B. and H. believe it is considered to answer as represented; they have also fixed it in connection with a new description of Iron Tank, which combines the qualities of the round pipe and the open tank, which may be pronounced the perfection of a Heating Apparatus for Horticultural purposes, particularly for Graperies, Epiphyte-houses, Melonpits, &c., &c. The arrangement is such that any gentleman or gardener may have the whole constructed so as to be put together with the greatest facility by the gardener, first sending a correct plan to 130, Fleet-street. A Prospectus may be had detailing the prices, &c.

THE KENSINGTON NURSERIES.

THE LEASE of one of these Nurseries expires shortly, and the Ground being required for Building purposes, Messrs. PROTHEROE AND MORRIS are instructed to offer to public competition the invaluable Stock on the smallest of these Nurseries, in the occupation of Messrs. FORBES and Co., and the Stock being far superior to any within a considerable distance, will afford Gentlemen, Noblemen, and others engaged in planting, a fine opportunity to supply themselves, not likely soon to recur. The sale is on the 4th March and following days, and includes ornamental Trees and Shrubs of every description, variegated and Green Hollies, Evergreen Oaks, and Cork Trees, large Fan and other Yews, twice transplanted Common and Portugal Laurels, Arbutus alaternus, Hemlock Spruce, &c. May be viewed prior to sale. Catalogues 1s. each, returnable to purchasers, may be had on the premises, of the principal Seedsmen, and of the Auctioneers.—American Nursery, Leytonstone.

TO GENTLEMEN, FLORISTS, AND OTHERS.

MESSRS. PROTHEROE & MORRIS will submit to public competition at the Auction Mart, Bartholomew-lane, on Thursday, March 14, 1844, and the following day, at 12 o'clock, about ONE THOUSAND STANDARD ROSES in fine condition, consisting of Bourbons, Hybrids, Perpetuals, Noisettes, &c. Also, a fine assortment of Dahlias in dry roots. May be viewed the morning of sale. Catalogues may be had at the Mart, and of the Auctioneers, American Nursery, Leytonstone.

THE SEVENTH EDITION of
JOHNSON'S GARDENERS' ALMANACK is just published by the STATIONERS' COMPANY, Price 3d.

WARNER & WARNER, Seedsmen, 28, Cornhill, London, beg to refer their Friends to their new and choice List of Vegetable and Flower Seeds in Harrison's Floricultural Cabinet for this month; and also to inform them a List of the newest and most approved seeds will appear in the *Chronicle* of the 9th March.

N. B.—Catalogues may be had on application.—Agents for POTTER'S LIQUID GRAND, in Quart Bottles, at 1s. 9d. each, with printed Directions.

The Gardeners' Chronicle.

SATURDAY, MARCH 2, 1844.

MEETINGS FOR THE FOLLOWING WEEK.

Monday, March 4	Entomological	8 P.M.
Tuesday, March 5	Horticultural	3 P.M.
	Linnean	8 P.M.
Wednesday, March 6	Society of Arts	8 P.M.

A LETTER from a "Manchester Gardener" reminds us that our remarks on PINE GROWING are not yet brought to a conclusion. The object of his inquiry is to ascertain whether the large Pines that have of late excited so much surprise are as well flavoured as smaller ones. The answer to that question is in the affirmative, as far as regards the Pines obtained at Bicton and Longleat. The latter we saw, and it was impossible to conceive Queens more perfect in all respects, fragrance, and therefore flavour, included. We are informed, upon evidence which we cannot question, that the same good qualities existed in the fruit obtained by Mr. W. Barnes; but, as we have repeatedly stated, we have no personal knowledge of the fact. As to other large Pines grown in other places, we have cautiously abstained from alluding to them much, because we understand that in some cases they have *not* proved of good quality. It is sufficient to know that the Queens at Longleat and Bicton were perfect; and on them we rest, and always have rested, our case.

And now a word with regard to the general question. What we have insisted upon is the *possibility* of growing Pines better than they have been ever grown before, unless in a very few exceptional instances; the *probability* of the whole system of cultivating this fruit being affected by the discovery of such a fact; and the *necessity* for those gardeners who fancy that they have arrived at the end of what there is to know bestirring themselves to improve their practice, if they would not be outstripped by better growers. The result has been exactly what we anticipated. Sensible men have betaken themselves to consider how far it is advisable or practicable to follow the advice that has been given. *They* never dreamed of taking to themselves the sharp remarks of ourselves and Mr. Barnes, for they felt that they in no way deserved them—and they were right. But the foolish drones clapped the cap upon their heads, found that it fitted them exactly, and were prodigiously annoyed at discovering that they could not take it off again. We trust they will continue to wear it, as a mark by which their neighbours may know them. We may possibly hereafter offer some other articles of dress for their acceptance.

Two things should, we think, be obvious. The first, that it may not be always as desirable to grow very large Pines, as it is to know how to do it; the second, that no one would expect them of a gardener whose master objects to supplying the necessary means.

What a gardener should do, is to set before his master the relative expense of growing Queens to the weight of 3lbs. or 4lbs., and 6lbs. or 7lbs.; and then to inquire which he prefers. In the majority of cases, he would find his master preferring the smaller size, *if well grown*; because it is only on special occasions that very heavy Pines are really wanted; and always to place on the table a Queen of 6lbs. weight where one of only 3 lbs. is required would be unnecessary waste. There is, however, no family where Pines are cultivated, in which it is not wished to have the largest possible fruit *occasionally*. If it were not so, the Providence and Enville Pine Apples, which have nothing but size to recommend them, would go out of cultivation. Again, the surplus Pines in many gardens are regularly sent to market, and in that case it would have to be ascertained which is the more *profitable*, a crop of very large, or of middle-sized, well-grown Pines. And it is in this way that market-gardeners probably view the question. They grow what best suits the market, and what will produce them the most profit. They may say that they could do better if it were worth while; and perhaps they could.

When, however, we look at the way in which the markets are supplied with Pines, it is impossible to compliment the growers on their skill. Often, indeed, one sees fair fruit; but anything very remarkable is rarely met with; and a large proportion consists of what we should not consider fit for any other purpose than that of the confectioner. This arises from nothing but want of skill on the part of the growers; for most assuredly good management will produce well swelled Queens from 3lbs. to 4lbs. at the same expense as is now incurred in obtaining ill-grown fruit of less than half the weight.

The man who *can* grow a crop of six-pounder Queens could never, under any circumstances, produce such things as we now see in too many places. Pine-growers should imitate the florists; they should place their standard of perfection very high, and should strive to approach it as nearly as they can, without being discouraged if they do not reach it.

WHEN we consider the infinite variety of objects presented to the eye in all the varied scenery to be found on the earth, it becomes clear that man must be endowed with faculties enabling him to derive pleasure from contemplating them. It is not enough that man should perceive there are things present external to himself; he must have power to distinguish one thing from another. Seeing the necessity of this, it is proper to consider what these powers are, before we think of their exercise in the profession we are attempting to illustrate. This is rather an extensive range of subject, but we shall be brief, studying merely to give useful hints, and leaving those who may feel desirous of deeper research, to satisfy themselves by applying to special sources of information.

After the perception of the presence of an object,—its occupation of space—perhaps we regard the secondary one to be its magnitude in comparison to our own dimensions, or to those of other objects. We have, therefore, a faculty to perceive magnitude or size, and a faculty to compare one magnitude with another. The next perception may be that of the boundaries or outline of the object—that is, its form, or shape. Here we speak merely as if the object were flat. When an object is not flat, but a solid, we are enabled to discover the entire form by the assistance of light and its degree of dilution; in ordinary language, shade. Though shade be essentially shadow, it is a useful conventional term to distinguish when it relates to the parts of form which it brings out to the eye; while shadow is employed to denote the effect of interruption of light by an entire mass of matter independently of every part of its form except the outline. The ascertainment of form by the sense of touch we need not consider; for, Landscape Gardening has to do only with perceptions excited through the eye. We have, then, a mental faculty, enabling us to distinguish forms which are of endless variety, made up of lines and surfaces, straight and curved. Outline depends on form; and, therefore, when agreeable outline is required in a landscape, selection is to be made of objects having forms suited to produce it. But it must be observed, care should be taken in selecting forms for an outline, that they are in other respects suitable to the position in which they are to be placed, and not disagreeable in themselves individually. Hence, this faculty of form must be possessed in a high degree by the Landscape Gardener; so that this perception may be quick in regard to the supply of what may be wanting, and to the removal of what is unsuitable. There is, besides, a perception of harmony required—of suitableness—of fitness, independent of simple form. There is, in the combinations of forms that which may be pleasing, and that which may be offensive. Indeed, in this consists the chief power of a Landscape Gardener who is fitted by nature to follow the profession. Metaphysically speaking, it is probable that this perception of harmony may belong to the faculty of form. It may be a faculty independent of it, but it is claimed by others also, and on that account seems to be an adjunct, or even an integral part of each. The phrenological faculty of ideality scarcely seems to embrace it, though it may assist the function; and without further discussion we hold it for the present as belonging to the faculty of form—but not exclusively.

It is obviously necessary to the Landscape Gardener to have an acute perception of the relative position of objects. This is undoubtedly a special faculty, and to it belongs the memory we have for places, and the power of finding our way. In grouping, objects may be placed incongruously in relation to each other, however agreeable their forms may be individually. If we feel pleased with one mode of grouping a certain number of objects, and displeased with another mode, it is obvious we possess a peculiar faculty different from simple comparison—one which enables us to derive satisfaction of a distinct kind from the perception of a particular arrangement.

There is another faculty connected with arrangement, and meriting special attention, and with which we will for the present conclude. We refer to the faculty of Order, or we may, perhaps, rather name it Symmetry. The disposition to keep things in order, that is, in their proper places, is not what is meant; but the arrangement of objects according to size and form. For example, let us take four objects of the same height, and four that are taller. In arranging them we may set down a tall one, then two short ones, next to them two tall ones, then two short ones, and lastly a tall one, lllll; or, two tall ones, four short, and two tall, llssll; or two short, four tall, and two short, ssllls; or one short, two tall, two short, two tall, and one short, slllls; all these are symmetrical. But other arrangements, such as sllslll, llsssl, ssllll, and so on, are not symmetrical. The faculty which leads us to observe symmetry is more necessary in Architecture than in Landscape Gardening; but still it is necessary, if for no other reason, in order to put the practitioner on his guard against stiffness, which is the result of too great a predominance of the faculty. The Landscape Gardener, however, ought to be able to perceive it, to make use of it where it may be proper, and avoid it where it would be absurd. Some of our readers may know the anecdote of a worthy Gardener who had this faculty in a high degree. It happened that the stocks were placed at a corner where one road branched off from another, not far from the residence of the gentleman whom he served. They had long been disused; one morning, for the first time, our gardener saw a man locked into them, rendering the whole thing very conspicuous. Towards evening his master happened to pass that way, and was surprised to see stocks on the other side, and a man in them also. He asked the gardener if he knew the cause of this, when he replied that he had considered it very awkward to have a man in the stocks only on one side, and that he had caused the carpenter to make another, and hired a man to stand in it, for the sake of uniformity.—*G.*

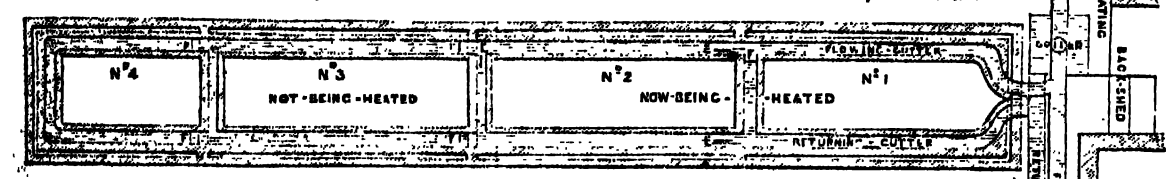
ON THE DISEASES OF PLANTS.

A LARGE class of the diseases which affect plants, and that a very formidable one, both as regards number and their disastrous consequences, is attributable to the attacks of various species of Fungi. To them, no less than to the minuter insects, are due many of the appearances which are known and dreaded by cultivators under the name of Blight, though frequently without the slightest suspicion as to their nature or origin. The noxious parasites themselves are many in number, and various in structure. There is no part or organ which is not, during some period of its growth, subject to their ravages. The leaves, the flowers, the anthers, the germen, the seed, the softer portions of the stem, or even occasionally the woody twigs and smaller branches; the roots, and finally the harder internal tissues, are in their turn affected by some one or more of these enemies, and in many cases totally destroyed by their agency. Nor are their attacks confined, as has been often supposed, to unhealthy organs or individuals, though there may often be a morbid condition of the plant predisposing it to such attacks; for it has been shown that where, under favourable atmospheric conditions, the spores, or reproductive organs of these productions have germinated, they have in many cases a power of establishing themselves upon the most healthy living tissues, and this not only in the vegetable world, where it, perhaps, may not appear surprising, but even in animals in full health and vigour. Mr. Hassall has shown, in a series of papers read before the Microscopical Society of London, and in specimens handed round at one of the meetings of the Linnean Society, that perfectly sound fruits are soon completely destroyed if inoculated with certain species of mould; and these observations have since been extended by him as regards Lettuces, and other vegetables, as were published in Aug., 1843, in the "Annals of Natural History." Effects like these had previously been produced by Messieurs Audouin, Bassi, and Balsamo-Crivelli, especially the former, whose papers in the "Annales des Sciences Naturelles" are well worth attention, by the inoculation of the mould (Botrytis Bassiana), which commits such ravages in silk-worm establishments, both before and after the spinning of the cocoon. And not only were the caterpillars of the silk-moth affected by this inoculation, but those of other moths; and, in some cases, other species of mould were developed from their internal tissue when exposed to the air. A familiar instance of this living death may often be seen in autumn in the case of flies, which, under the attack of some species of Fungus at present imperfectly understood, glue themselves by their proboscis to the ceiling, to leaves, pieces of string, or other objects that fall in their way, and then patiently wait for the consummation of their disease. Dr. Hannoon also, as recorded in "Muller's Archives for Anatomy and Physiology," succeeded in inoculating living salamanders, some of which died in consequence of the development of the mould. As this Fungus is very easily raised in a glass tube without any organic matrix, provided the air within the tube be of the proper degree of moisture, as has been shown by Dr. Montagne, it is not improbable that it would establish itself likewise on vegetables; but I am not aware that any experiments have been made on this point. And this would be the more likely, if, as Dr. Montagne supposes, it may possibly be the same species with Botrytis diffusa, though I am myself inclined to think that the latter species has a far more complicated structure. The subject, indeed, is one which deserves far more attention than it has hitherto received, and which is likely to repay well the labours of any patient and accurate observer; and though the spores of Fungi may not be so injurious as might be supposed from an opinion which I heard maintained by persons of considerable scientific attainments in France some years since, when the influenza, or, as it is called there, *la grippe*, was so prevalent and fatal, that it arose from the multi-

tudes of the spores of Fungi floating in the air, after a great Fungus season, which induced a diseased action of the lungs; still the numerous facts which have been brought forward of the effect which these bodies produce on animal tissues even of the higher tribes, seem at least to intimate that their effects, even as regards the human frame, may be of more importance than is generally suspected.

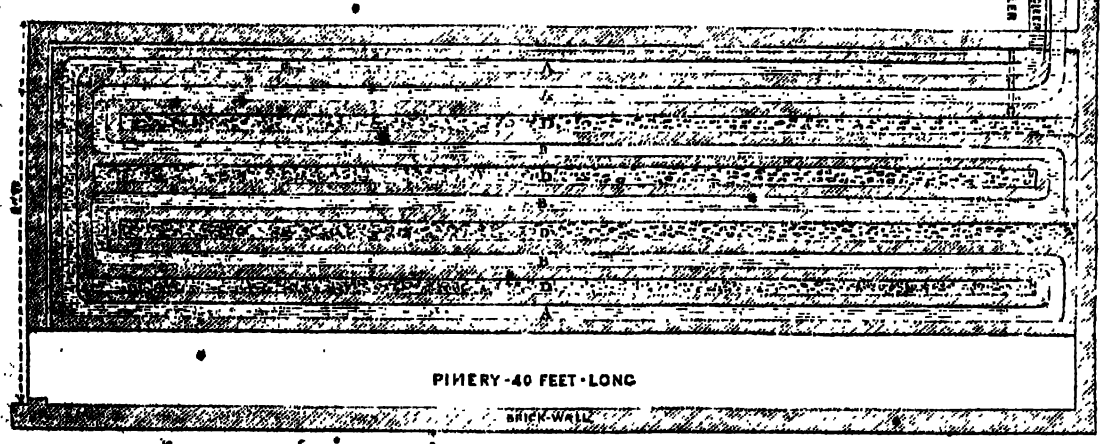
Their effects on plants are too evident to be denied, however difficult it may be in many cases to understand the phenomena which are presented to our notice. The contemporaneous but independent discoveries, however, of Léveillé and Corda as to the penetration of the mycelium of the Fungi, which produce rust and mildew, into the tissue of the plants, and its presence in those tissues before the actual appearance of the Fungus externally (discoveries which were in part anticipated, perhaps, by Dutrochet in his "Observations on Moulds," and by Balsamo as regards Botrytis nivea, Martius, a species which originates beneath the cuticle of the common Shepherd's-purse, but finds its way through the stomata without bursting the outer integument), have removed some of the difficulties which are connected with the subject, and will doubtless lead to a more accurate knowledge than at present exists respecting it. These phenomena are indeed in some cases so puzzling, that Hartig in the case of those Fungi which prey upon the woody fibre, and Unger as regards those which are more connected with the softer cellular tissues, have considered them, in accordance with the notions so prevalent with German Botanists as to the production of the lower orders of plants and animals, as absolute transformations of such tissues; an opinion exactly parallel to that of Dutrochet on the development of the globules of milk into a mould, and of Balsamo of the transformation of the particles of the fatty substance of caterpillars into the Botrytis.

We shall have occasion hereafter to advert to the opinions of M. Unger, which the discoveries of Corda and Léveillé have shown to have been put forward with a very imperfect knowledge—doubtless from want of a good modern microscope—of the real structure of the productions he was considering. The importance, indeed, of these discoveries cannot well be overrated, not only as regards the questions which arise of a more purely scientific nature, but in all considerations of the mode in which plants are attacked by parasitic Fungi, and the remedies which may be adopted against them. It is far from improbable that Unger may be again induced to take up the subject, and if so, we may be sure that it will not be without some interesting results, for it is very far from being exhausted. Within the last few weeks Dr. Montagne informs me that he has made some observations on the development of the spores, which bid fair to be of much importance. Of these a slight intimation has been given in the article Cryptogamie, published in the last Number of the "Dictionnaire Universel d'Histoire Naturelle." A fuller version will, I doubt not, soon be published.

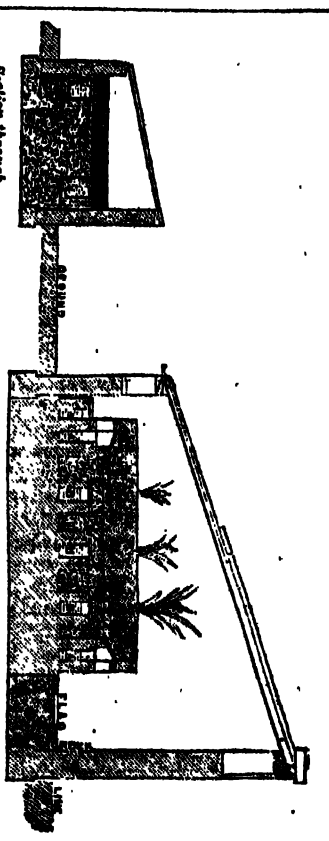


It is proposed, as part of a series of papers on the diseases of plants, to give as far as possible in a popular form, accompanied occasionally by illustrations, an account of those maladies which arise from the influence of Fungi. This will, I hope, prove so far interesting, as to elicit many important observations from practical persons, whose attention perhaps may not have been called closely to the subject, and remove from some minds the prejudices which have so long prevailed respecting the origin of these diseases. I cannot make any pretensions to novelty or original research, but the object in view will be to point attention to such points as may be most likely to instruct and interest.

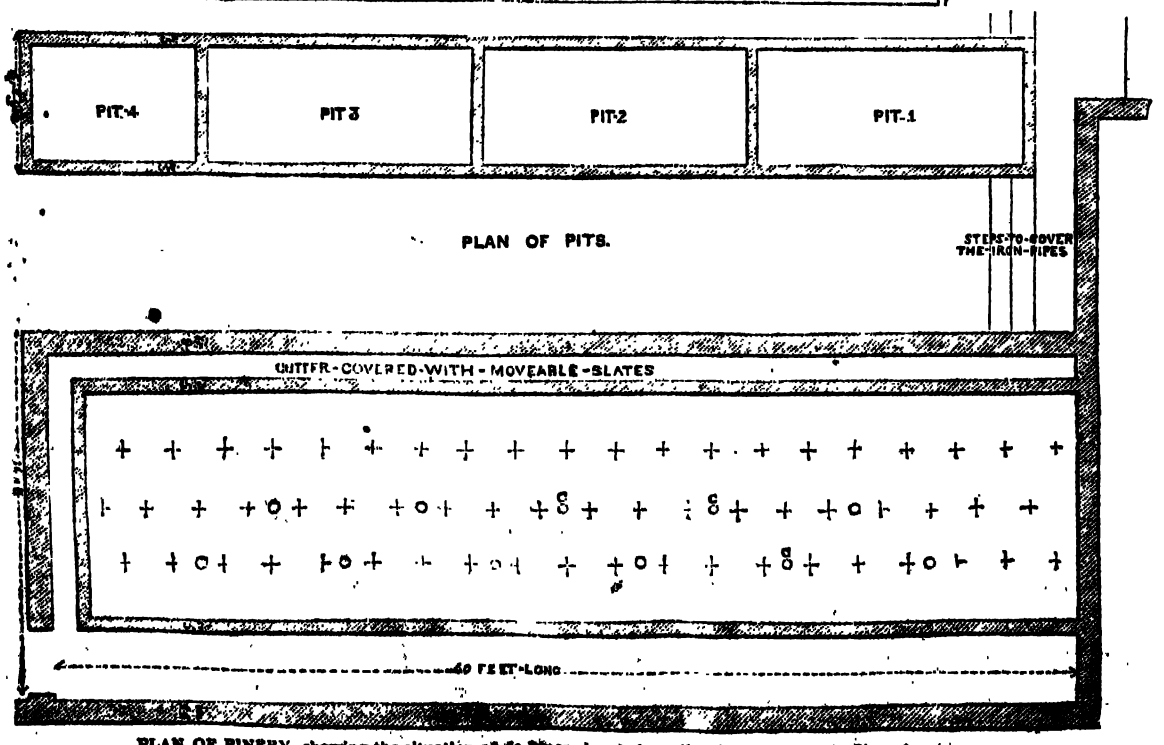
The most convenient course will be, with a view to avoid unnecessary repetition, to take the noxious Fungi in systematic order, commencing, however, with those which are lowest in the scale, though in this point of view the most important. I shall, however, first state briefly the effect on plants of other cryptogamic productions, which would perhaps not easily be included in any other division of the series; and then, as prefatory to the main subject, give a very concise sketch of that class which is to occupy principally our attention.—*M. J. Berkeley.*



PLAN OF WARMING A PINERY AND PITS, BY HOT WATER FLOWING IN GUTTERS;



Without any Fermenting Substance being used.



As Executed by Mr. FOSTER, Gardener to the VISCOUNT DOWNE, Benningbrough Hall, near York.

PLAN SHOWING THE GUTTERS IN THE PINERY AND PITS.

PLAN OF PINERY, showing the situation of the Pines placed above the Gutters; also the Plugs for steam.

Explanation of Plan & Section.

AAA Gutters 6 in. wide and 18 in. deep, built of brick lined with Roman cement, to warm the air of the house, also to moisten the atmosphere when required, by removing the slate covers.

BBB Gutters upon which the Pines are planted without pots; they have also 4-in. upright pot-pipes, with movable plugs, for steaming, marked C on the Plan. All the gutters are covered with thin blue slates steam tight. This house having been erected late in the autumn, there is sufficient moisture without removing any slates or plugs.

DDD Concrete, without lime, to allow the heat to pass into the earth above.

EEE Valves to the pits, now open, showing Nos. 1 and 2 being heated.

FFF Valves, now shut, showing Nos. 3 and 4 not being heated.

GG Stones into which the iron pipes are fitted, with flanges, water-tight.

References.—The heat at the roots of the plants 6 inches below the surface of this pit is 92°. The heat of the air of the house from three gutters, without any fire, is from 66° to 69°. Of the Pines placed in the house, some had shown fruit, some were showing, and others not; of those that had shown I never saw any make such progress in the height of the season; those that have shown since planted have come up remarkably strong; those plants that have not shown have made rapid growth, and no doubt will show fruit soon.

FAMILIAR BOTANY.

Morphology.—No. V.

[A kind friend has furnished us with the following, which we think it better to insert before proceeding with *R. E.*'s papers.]

"I FEAR that very few of your readers will be induced to study Mrs. Austin's literal translation of Goethe's 'Metamorphosis,' as it is given by your friend *R. E.*, in last week's *Chronicle*, enough to discover the full meaning of the author, physiological or poetical. Or they will perhaps be inclined to say, with *Mr. Dangle*, in 'The Critic,' that 'the interpreter is the hardest to be understood of the two.' The following attempt to make the translation more readable is at your service. I only hope that as *Mr. R. E.* has *under*-rated his own powers of diction, I may not have *over*-rated mine. I beg to say, in addition, that I have not the original German by me to assist me, and that it is a long time since I read 'The Botanic Garden,' in which I think the same subject is very Goethistically wrought out."—*P. P.*

Mark by what slow degrees, but ceaseless force,
The husky seed unfolds its tender charge
Of leaf and blossom, and enduring fruit,
When urged by earth's all-fructifying juice,
And more attractive light,—life-giving light,
Holy and pure!—Till now, the nascent power,—
Mysterious germination,—slept unseen;
And root, and leaf, and bud enfolded lay
Enshrined within their husky tenement,
(Incipient foretypes of the coming plant,)
In silent life, half formed and colourless;
But soon, replete with earth-giv'n moisture,
It lifts itself above surrounding night,
And breathes the incense of the open day.
Still is its early dawn distinguished
By simple forms; for even plants confess
The Infancy prepared for all things earthly born.
Quickly proceeds the growing impulse then,—
Joint upon joint, and leaf on leaf arise,
In order predetermin'd,—not of chance,
But variously unfolding, points and parts,
And tangled edges,—parts unseen before,
Scarce moulded yet within the parent stem.
So step by step the vegetable wonder draws
Its great completion: ribbed and indented,
On the exuberant stem it stands secure,
And challenges the soul to admiration.
But Nature now with powerful hand arrests
The quick enlargement; gently she leads on;
In smaller channels, and for nobler ends,
Diverts the all-important sap; and now,
The ranker vegetation binding those,
Structures more perfect, more elaborate spring.
Quickly the slender flower-stalk starts to view,
Leafless and bare; save where in subtle shapes
The curious eye detects the tiny forms
That circle round the head, innumerous;—
Leaflets compressed, in sheltering calyx bound,
Each like to each, in stated order set.
The crown unfolds, the calyx gently yields
Its many-coloured charge; and Nature now
Blooms in her gay, magnificent attire;
Ever anew thy admiration moving,
Anlimb on limb upreared, the noble flower
Waves o'er its frame of ever-changing leaves.
But still this glorious show but heralds th
New operations,—with all-powerful hand
The work proceeds: the many-coloured leaf
Retires abashed, and tender forms crowd round.
Affianced couples they, claimants intent
On Hymeneal rites, whose quick'ning powers,
(Delicious odours streaming all around,)
Perfect the destined union. Now compact
Together swell the teeming germs; with fruits
The bounteous mother's well-filled lap o'erflows.
Nature's eternal circle here is closed:
But straight renewed,—another ring succeeds.
Link within link entwined, the chain 's prolonged
Throughout all Time,—to all, and sev'ral given,
Life within life—a Being infinite.—*P. P.*

Home Correspondence.

Heath Edging.—It is observed by Dr. Hooker, in his "British Flora," page 181, that Calluna vulgaris makes an excellent edging to garden-plots, and bears clipping as well as Box. The superiority of Heath as an edging is another confirmed by a recent notice in the *Gardeners' Chronicle*, stating "that Heath-edgings have been successfully introduced into the Speaker's gardens at Heckfield-place." About four years ago edgings were required in the Speaker's gardens, and in the adjacent common a few patches of young Heath were found that had sprung up where the surface of the ground had been pared off a few years before; from these an edging was formed by cutting the surface into narrow strips, about two inches wide and two deep. Those pieces, on being brought to the garden, were laid in a line, and formed the edging at once. The ground was previously prepared for their reception, and some Heath-mould was added to encourage growth. The Heath is cut twice a year, and forms a neat and pretty edging. For this purpose Heath deserves more attention than has hitherto been given to it, and I hope to hear further particulars respecting its utility.—*Thomas Berry.*

Lily of the Field.—I have seen it mentioned in the *Gardener's Chronicle* that most probably the Ixiolirion montanum, which is I believe a beautiful Amaryllis with a pale-blue flower, is the plant alluded to in the New Testament as "the Lily of the Field," surpassing the glory of Solomon when arrayed in all his splendour. I met with a passage the other day, militating against this idea, which I think you may like to have pointed out. The passage I allude to occurs in the 9th of St. Cyril's "Catechetical Lectures" (Oxford ed. in "Library of the Fathers," page 94). The Bishop was pointing out to the catechumens the power of the Almighty as displayed in the things which are seen. "Contemplate," he said, "the spring, and the flowers of all kinds, in all their likeness still diverse from one another; the deep crimson of the Rose, and the exceeding whiteness of the Lily. They come of one and the same rain, one and the same earth; who has distinguished, who has formed them?" &c. Cyril is said to have delivered these Lectures in Jerusalem about A.D. 348, and he was likely therefore to have alluded to the same kind of Lily—one no doubt well known—as that on which our Lord based his remarks. I own I feel some doubt whether the word "whiteness" in the extract is an accurate translation of the original; the Greek word might perhaps only express "paleness," or "clearness;" but as I have not the Greek original to refer to, I cannot satisfy myself on this head.—*F. S.* [All speculations as to what the Lily of the Field may have been, are set at rest by the discovery that our Saviour *must* have referred to the Lilium Chalcedonicum, as is proved at p. 854 for 1842.]

Analysis of the Raspberry.—The following is the analysis of the Raspberry, which I extracted from some work; but the authority I neglected to note down, viz.:—

Silicic Acid	0·25
Phosphate of Lime	3·65
Carbonate of Lime	2·40
Potash	3·24
Soda	0 50
Ox. Manganese	1·00
	14·04

It was stated that the Raspberry most generally springs up where fields had been burnt over, and also by the sides of decomposing stone walls.—*W. P. Keane, Leybourne Grange, Town Malling, Kent.*

Large Pine-Apples.—Respecting the large Pines mentioned at p. 102, in addition to what is there stated, Mr. Dixon wishes us to publish the following, viz.:—"That the gill suckers were heartless, and of very small size; that the weight of the suckers on the one weighing 11 lbs. 15 oz. was 3½ oz.; and that those which grew on the one weighing 14 lbs. 12 oz. were very small and quite heartless."

Melons.—In answer to your correspondent, who asks which is the best Melon for preserving, "M. P." begs to state that she has tried several, and that none answer the purpose so well as the old Rock Melon.——Another correspondent confidently recommends the Yarmouth Prize Melon for preserving, and Mr. Sherwood, of Stamford Hill, states that the best Melon he has ever grown for that purpose is Cuthill's Early Melon. He informs us that it is well flavoured, has very thick flesh, that it is a great bearer, and ripens earlier than any Melon he has tried.

The Gladiolus.—I have read in the *Chronicle* lately an extract from J. de Junghe, in the *Revue Horticole* for Sept. 1813, headed *The Gladiolus*, which contains many inaccuracies. In the first place, Gladiolus communis, which is a native of the south of Europe, is much less common at present in the gardens of England than Byzantinus, being less hardy and liable to perish. That "these two species have afforded a great number of varieties of different colours, such as White, Rose-colour, Orange and Vermilion, Purple and Lilac," is utterly unfounded. There exist no varieties of G. Byzantinus in the gardens. There are several natural varieties of G. communis from different localities in Italy, but they are little known, and afford no great variation of colour, except a whitish one. G. segetum, which has the seed without the winged or foliaceous margin, has a white variety, which M. Bouché makes a distinct species, but to which no native locality is assigned. G. Boucheanus, crispiflorus, caucasicus, and some other natives of Europe and Western Asia, are unknown to M. de Junghe, but do not afford the colours which he mentions. The plants of various and brilliant hues to which he alludes are those which were raised by myself, when I lived at Mitcham, about the year 1810, between G. cardinalis, blandus, angustus, and tristis. The intermixed produce from their seed, which is furnished abundantly, and the produce of similar intermixtures has been obtained by other persons from the same plants since. Other crosses were made about the same time by me at Mitcham, but are less known. The plant named G. floribundus, and so called by most vendors, is totally unlike G. floribundus, which is an old Cape species, figured long ago in the *Bot. Mag.* The published name of the G. floribundus of the shops is G. oppositiflorus. It is a native of Madagascar, and probably of the Natal colony also. It was found to breed readily by intermixture with the Cape mules, and the species from which they were produced, as well as with G. natalensis, otherwise called Psittacinus, or Dahleni. The crosses are as much English as Belgian productions. The G. ramosus of the shops, which varies in colour in different individuals, is a cross between G. oppositifolius and the mules by G. cardinalis and cardinalis itself. It thrives much better in Belgium than with us, because the soil there suits it better. Many such, and some handsomer, with an intermixture of tristis, have been raised and flowered by me, but are very subject to perish in my soil. The Gladiolus, called Gandavensis by Mr. Van Houtte, of which he is stated to possess the whole stock, was raised abundantly by me, being the produce of G. oppositiflorus by Natalensis, but it did not thrive as those raised in Belgium. Some, however, which were raised as early by Mr. Bidwill in this country, and taken by him to Sydney, far exceeded the Belgium plants in growth and vigour, and the roots thereof brought back by him from thence flowered with greater strength than those for which I was indebted to Mr. Van Houtte; some were exactly similar to his plants, and one in particular with a very different posture of flower. I have now seed obtained from his bulbs set last spring in Devonshire, crossed a second time by Natalensis. As yet I have no cross on the correctness of which I can rely between Natalensis and any Cape species or mule; nor between any Cape species and species of the Northern hemisphere. G. Colvilli is one of the best varieties of the crosses of tristis with cardinalis and cardinalis-blandus. The formosissimus mentioned is one of the Cape mules, but inferior to insignis.—*W. Herbert, Manchester.*

Seedling Auriculas.—I took several pots of green-edged Auriculas, and placed them together in a shady place, giving all possible air. As they came into bloom, I pulled off all the flowers from every Self and Alpine. I had seed enough, but among the seedlings only one proved an Auricula, with a gray edge, indeed, but worthless. The rest were all Alpines and Selfs, of better properties than I had met with in seedlings raised from Alpines. Some of them had nine or ten petals.—*O.*

American Bug.—The following is from "Waterton's Essays on Natural History," (3d edit. p. 276). After mentioning several ineffectual applications, such as mercurial preparations, decoction of Walnut-leaves, spirit of turpentine, for destroying the downy white insect or American Bug on Apple-trees, the author says:—"Despairing of success, I was on the point of quitting the field and leaving the Bugs in undisturbed possession of it, when I began to conjecture that I had not gone the right way to work. I reflected that none of my applications could have penetrated sufficiently deep into the curved and knotty sinuosities of the diseased parts, and that on this account there would be a sufficient force of the enemy left alive to recommence its depredations at the first favourable opportunity. Wherefore I concluded that nothing short of the entire destruction of the eggs, the young, and the adult, could save the trees from ultimate ruin. Knowing that the Bug could not exist if totally deprived of air, I resolved to bury it alive, and this I effected by an application, at once the most easy and simple that can be imagined—it costs nothing. I mixed clay with water till it was of a consistency that it could be put on to the injured parts of the tree, either with a mason's trowel or with a painter's brush. I then applied it to the diseased places of the tree, and it soon smothered every bug; a second coat upon the first filled up every crack which showed itself when the clay had become dry, and this resisted for a sufficient length of time the effects both of sun and rain. The sickly parts, now effectually freed from the enemy which had been preying on their vitals, were placed in a state to be cured by the healing process of Nature, and that Nature has done her duty, my Apple-trees amply testify."—*Vertumnus.*

Hampton Court.—In reference to Hampton Court I should be so sorry to see "Q.'s" wishes on the subject realised—not that I think there is the slightest chance of it—that I hope you will allow me to address a few words to your Journal, of which I am a constant reader. Did it ever occur to him that there are thousands of shopkeepers' clerks, men of business and different professions, who are occupied during the whole day for every day of the week? That Sunday is the only day on which they can take a walk with their families, and breathe the fresh air after inhaling the smoky atmosphere of London for six days? Is it ungodly or profane for them to admire the fresh green Grass—the fine old trees—those temples not made by hands—to feel what a beautiful world this is, and bless the God who made it? Does the cheerful voice of the young visitors grate upon his ear, that he calls them profane and a nuisance? I always make a point of going to church on a Sunday; residing in London I have been all my life fond of every plant, from the Oak to the Lichen, and the pleasure I feel in a ramble about the walks of Hampton Court and Bushy Park is no doubt equally felt by hundreds there. I always found I had plenty of time to go to church also, and it certainly never occurred to me that I was a sabbath-breaker. I am sure that her Majesty, who, as "Q." says, is "the head of the truly Apostolic and purely spiritual Church," is well aware that the best way to make her subjects love and fear God, and be dutiful to herself, is to give them the means of innocent amusement, and of cultivating the purest taste—that for Nature—and that they will be encouraged to show their happy faces, free from care for one day in the week, in Hampton Court. As for the respected gardener there, I should doubt much whether he will thank his friend for bringing this forward; he must have known what would be required of him, and of course need not stay there longer than he likes. I fear "Q." is of a sour disposition; I really should be almost afraid of his blighting the plants if he was my gardener.—*Bp.*——A second communication is as follows:—"I regret to observe that your correspondent "Q." should have made such bitter complaints on the practice of opening these gardens to the public on Sundays. I would ask how professional men, tradesmen, assistants in shops, &c., can have a more innocent recreation than enjoying a walk with their families in the Palace gardens after being confined closely to business during the whole week, without any opportunity of breathing fresh air? Is it fair or charitable to style such people a host of ungodly, profane sabbath-breakers? I strongly suspect "Q." to be from the north side of the Tweed, by such a display of the narrow bigoted spirit of Calvin and John Knox. With regard to the gardeners, why cannot they take turns of duty every alternate Sunday, or even every third week? Thus they might attend Divine service without hindrance, and spend the day as they wish."—*C. D.* [Having allowed the letter of "Q." to appear, we cannot refuse insertion to these; but we feel that the subject is not suited to our columns, and therefore we would beg our correspondents not to carry it further.]

Societies.

BOTANICAL SOCIETY OF LONDON.

Nov. 29, 1843.—Seventh Anniversary Meeting. The Treasurer in the Chair. From the Report of the Council it appeared that 13 new members had been elected since the last Anniversary, and that the Society now consisted of 159 members. The Report of the Herbarium Committee was read, and stated that many interesting British plants had been presented, including several species of Carices collected by the late Mr. G. Don, which were

presented by Mr. S. P. Woodward. Specimens of Carex paniculata (Willd.), Bouchaeaia texana (D. C.), Spiranthes gemmipara, Convallaria bifolia, Statice rariflora, and other valuable plants, had been received. Mr. Edwin Lees had presented a collection of British Rubi, comprising nearly all the species. Numerous interesting Irish plants had been received from Mr. Andrews, including many duplicates of Trichomanes speciosum. The plants sent to members in return for their contributions had given much satisfaction, and in nearly every instance the Committee were enabled to send the return parcel within a fortnight after the receipt of the contributors' own parcel. Since the printing of the catalogue of British plants, now used by the members in marking their *desiderata*, several new species have been added to the Flora of this country, which of course do not appear in the catalogue. As far as these novelties can be obtained, the Committee will distribute them through the parcels sent out to contributors, together with any other specimens which may afford the opportunity for correcting errors of nomenclature, or in any way elucidating the Botany of Britain. For the common benefit of members it is particularly requested that contributors will send as many duplicates as they can of all such novelties. Among the specimens now ready for distribution are the following:—A few specimens of Statice rariflora, obtained through the kindness of Mr. Notcutt; an ample supply of the true Crepis biennis, presented by the Rev. A. Bloxam; the true Primula elatior (Jacq.), received from Mr. E. Doubleday, together with the varieties of P. vulgaris, which are often mistaken for the former. The true Eriophorum gracile (Koch.) known to very few English botanists before the summer of 1842; Linaria spartea, naturalised at Walton in Surrey; Bromus commutatus (Schrader), so very frequently misnamed B. arvensis (Lerou); varieties of Betula alba, which are described as species by several botanical authorities; Festuca loliacea passing into F. pratensis. The original labels are carefully preserved, and those which are not required for introduction into the reference Herbarium, along with the specimens will be fastened into a book, as a permanent record of localities. Dr. Ayres has sent a portion of the Flora of Thame, Oxfordshire, and engaged to complete it; and a full set of the flowering plants of Esher, in Surrey, has been collected, and will be sent to the Society as soon as they can be glued down in the manner prescribed by the committee. Other members are collecting the Herbaria of their respective districts, and the committee hope next year to report the addition of several Local Herbaria. The Foreign Plants received far exceeds that of any former year. The Horticultural Society of Cornwall had sent a very large collection of East Indian plants, comprising specimens collected at Madras by Dr. Wight, and at Assam by Major Jenkins. A very large collection of North American plants had been received from Dr. Gavin Watson and Mr. R. Kelvington, and Mr. E. Doubleday had presented 300 species from Ohio. A collection of specimens from Western Australia had been presented by Mr. Turner, and Mr. Gerard had sent valuable plants collected at Sierra Leone. British Ferns have been received from various members, and in every instance where specimens have been received from localities not hitherto recorded in the collection, the most characteristic have been selected, and introduced in accordance with the principle laid down by the committee, of extending the series to every locality that can be obtained for the rare species, and every county or district for the more abundant. It has also been made an object to ascertain the geological range of each, as well as its geographical distribution. The abundant supply of Lastrea cristata, Asplenium lanceolatum, Adiantum capillus, Veneris, and Trichomanes speciosum, has enabled the committee to distribute them to all who applied for specimens. The following Mosses, new to the British Flora, have been presented by Dr. Thomas Taylor. Trichostomum saxatile (Taylor, M.S.), and Bryum recurvifolium (Taylor, M.S.), and the following new species of Hepaticæ, Jungermannia reclusa, fragilifera, germana, and riparia together with authentic specimens of the new Dicranum scoparium, and Dicranum Dillenii. Mr. G. H. K. Thwaites has sent a large collection of Mosses, chiefly collected by him in the neighbourhood of Bristol, including many new species. Dr. Ayres has forwarded specimens of Hysterium rubrum and Peziza caulicola, discovered by him in Oxfordshire. In concluding their Report the committee called upon the members for renewed exertions to make the collection forming by the Society as complete as possible, and to render their Herbarium a permanent standard for the determination of plants; and members and contributors are particularly requested to send monstrosities and any specimens differing from the common form. The reports of the council and Herbarium committee were unanimously adopted; a ballot then took place for the council for the ensuing year, when J. E. Gray, Esq., was re-elected president. John Miers, Esq., J. F. Young, M.D., and A. Henfrey, Esq., were elected new members of the council in the room of C. Francis, Esq., H. A. Messen, M.D., and Adam White, Esq., who retire. Messrs. Reynolds, Daness, and Sansom, were respectively re-elected Treasurer, Secretary, and Librarian.

Dec. 13.—The president nominated Hewett C. Watson, Esq., and John Miers, Esq., vice-presidents.

Reviews.

Upon the Growth of Plants. By Julius Munter. (Botanische Zeitung, 1844.)

The Author of this paper has previously made communications to the "Botanische Zeitung," on the growth of the various parts of plants, and refers to the papers of Schmitz in the "Linnæa," and of Harting in the "Tydschrift voor Natuurlyke Geschiedenis en Physiologie," as contributions to the same subject. Schmitz's paper was on the growth of Fungi, and Harting on the influence of external agents on the growth of plants, such as the time of the day and of the year, the degree of warmth, the dampness and dryness of the atmosphere, and the influence of a quiet or ruffled atmosphere. The author has repeated most of the experiments of Mr. Harting, and in this paper makes remarks upon them in detail, and confirms their general results. He thinks that Harting has not duly estimated the influence of light on the growth of the various parts of plants. He had found, as the result of his own experiments, that a diminution of light had increased the growth of the internodes, as well as of the stem generally, whilst it greatly prejudiced the growth of the leaves.

In the author's previous papers he had given the results of experiments performed in his own room, where consequently the plants were exposed to little climatic change; but in the experiments detailed in this paper they were performed in the open air. The experiments are divided into two series; the first for the purpose of ascertaining the law of the growth of the internodes, the second for obtaining the same law in relation to the leaves of dicotyledonous plants. In order to ascertain the growth of the internodes, an internode was divided into equal parts, and measured at certain intervals. The plants thus experimented on were, the Acer pseudo-platanus, the Vitis vinifera, and Sambucus nigra. The following is an example of these tables. The plant was Vitis vinifera, and the internode was the fifth on a branch of that year's growth, *a* is the basis of the internode, *e* its upper part.

Day.	Weather.	Temperature. Reaumur	a. b.	b. c.	c. d.	d. e.
June 13	Rain.	14·0	6 6‴	6 0‴	6 0‴	6 0‴
June 15	Bright.	15·0	8 0	9 0	9 5	8 5
June 16	Bright.	17·0	9 5	10 0	10 5	10 0
June 17	Bright.	18·0	11 0	12 5	12 5	12 5

From experiments thus performed, he comes to the conclusion that the extension of the internodes goes on at first in all parts, and first ceases at the base, whilst the upper parts still go on lengthening, and that gradually it ceases also in those parts. This remark, however, does not apply to the growth of the internodes of monocotyledonous plants. From other experiments it appeared that light prevents the growth of the internodes, as plants in the shade developed more space in the internodes than in the sunlight.

The experiments upon the leaves of plants were made in the same manner. The petiole, the midrib, and the lateral veins were marked off into equal spaces, and their growth observed from day to day. From experiments made upon the Hazel and the Vine, the author came to the conclusion that the petiole ceased to grow in a centrifugal direction, whilst the midrib and lateral costæ ceased to grow in a centripetal direction. In the simple leaves of the Hazel, the point of the leaf ceased to grow first, then the edge down to the base. The same took place in the lobed leaves of the Vine, the point of the midrib-lobe ceasing to grow first, and so on to the base of the whole leaf. The same results were obtained from experiments on the growth of the leaves of Ampelopsis quinquefolia. It might have been supposed that as pinnated leaves are considered only modifications of lobed leaves, that they would obey the same law of cessation of growth; but from experiments made on the leaves of Rhus typhinum and Fraxinus excelsior, it was found that the midrib of these leaves obeyed the law of the centrifugal cessation of growth, whilst the end and side leaflets ceased to grow centripetally. The paper concludes with a table of experiments on Acacia lophantha in proof of the correctness of these conclusions, and the author promises to pursue the subject further.—*L. E.*

EXTRACTS FROM NOTES OF A VISIT TO EQUATORIAL AMERICA, IN SEARCH OF PLANTS AND SEEDS FOR THE HORTICULTURAL SOCIETY OF LONDON. By Mr. T. HARTWEG.

(From the "Horticultural Transactions," Vol. III., Part [illegible].)

I ARRIVED on the 3d of December, 1836, at [illegible] days' riding, over a country without [illegible] Cruz. Two ravines, brought me to Zaquapan. [illegible] For [illegible] Cruz to Santa Fé, the [illegible] lay over [illegible] three leagues, from Vera side, covered [illegible] by *Convolvulus maritimus*, a large round-[illegible]*antia*, a *Croton*, and, above all, by *Mimosa pudica*. At Santa Fé the vegetation became more luxuriant, and the small shrubs were replaced by stately *Palms*, *Acacias*, several *Scitamineous* plants, and various *climbers*.

ZAQUAPAN is placed at an elevation of about 3000 feet above the level of the sea, on the eastern declivity of the snow-clad Orizaba, which attains the height of more than 17,000 feet; the climate is temperate, and the place surrounded with the richest vegetation I ever saw in Mexico. Upon leaving the savannahs, which are covered with a scanty undergrowth, I entered a forest of *Oaks* (*Quercus Jalapensis*, *H.B.K.*) and there a change took place as if brought on by magic; *Orchideæ*æ, for which I had been on the look out since I left Vera Cruz, and of the finding of which I had given up all hope, considering the elevation I had attained, appeared here in the greatest abundance; the Oaks actually seemed to groan under their weight; *Maxillaria denia* and *tenuifolia*, forming festoons, and hanging gracefully over the branches they were growing on, seemed to strive with the larger species of *Tillandsia* for their existence. It was here I met with the beautiful and new *Cyrtochilum maculatum*, and the varieties of it now become so common. In the ravines or rocks I found *Maxillaria aromatica*, *Epidendrum serratum*, *equitans*, *umbellatum*, *fuscatum*, *cochleatum* (this latter with nearly all its varieties), and *Acropera Loddigesii*. In the more exposed situations, particularly on trees overhanging the perpendicular sides of the ravines, *Stelis ciliaris*, *Dimima polystachya*, *Isochilus linearis*, *Polystachya luteola*, and the little plant that now bears my name (*Hartwegia purpurea*) were common. The first plant of *Brongniartia glauca* I met with was on a *Quercus*, but, in a wood descending to the savannah; but I afterwards found it on Oaks in abundance near this station. To grow this plant, as well as *Hartwegia purpurea* to perfection, I would recommend a temperature of 65—70° of Fahr., and to be kept in the driest part of the stove. The same treatment may be applied to the thick-leaved *Epidendrums* and *Oncidiums*. Near the same locality I found *Berberis trifoliata*, forming a shrub 10 to 12 feet high, and at the time covered with its black berries on spikes more than a foot in length. In the more open places, among Grass, the *Cobadilla* or *Asagræa officinalis* was ripening its seeds on a stem four feet high; the roots, leaves, and particularly the seeds of this plant are used by the muleteers, in a state of fine powder, for killing the maggots in the wounds of their beasts, and occasionally an infusion of it is used in extirpating certain cutaneous which may be found on the heads of the lower class, but its employment is not so general as the occasion for it. The sweep plant, *Agave saponaria*, was found in the same locality, throwing up its flower-stem like a tuberose, to which, in fact, it bears much resemblance. Its thick, fleshy root crushed is a good substitute for soap, and is abundantly used by those who are too poor to buy that article.

[After quitting the city of Mexico] my first excursion was to the Grande, the highest point of the range of mountains of Guanajuato, where I was rewarded with *Garrya oboata*, then in flower, forming a shrub six feet high; I afterwards found it more commonly on the Rufa, a bluff rock a league from Guanajuato. *Arctostaphylos pungens* has also been found in these stations, both in flower and fruit. *Berberis fabiolaris*, forming a shrub 8 to 10 feet high, was covered with flowers, as well as *Ribes campanulatum*. In another excursion I found, both in flower and fruit, a second species of *Garrya* (*G. [illegible]*) forming an evergreen shrub 12 to 15 feet high, with the *Madroño*, or *Arbutus denuiflora*, forming a shrub, or small tree, covered with delicate white flowers. In the more sheltered situations, in the ravines near the town, *Clematis pubescens* was in full flower. *Oaks*, which cover the greater part of the mountains, were in great variety, but the acorns of the preceding year being all dead, I could procure neither seeds nor specimens. Pines were nowhere to be met with.

On the 13th of April I arrived in Lagos from Guanajuato. The only things worthy of notice from this station were *Jatropa longifolia* and *Lælia majalis*; the latter species I found at an elevation of about 6000 feet, growing on Oaks, and producing such a profusion of large pink flowers in May, that even the Mexicans find it attractive, and stick a few plants on the Limes (*Citrus medica*) growing before their houses. Of this I sent an abundant supply of plants, but as it has resisted all attempts at cultivation, I would recommend it to be kept in the driest part of the stove, and to be liberally supplied with water during the summer months only. In fields *Lupinus Hartwegii* was common; this seems to be quite stationary, having nowhere else been met with.

On the 17th of June I arrived at Lagos, where I found the same barrenness during the dry season as at Leon; and after a month's fruitless wandering, I left, on the 18th of July, for Aguas Calientes. Of the more interesting plants found near Lagos I may mention *Milla biflora*, bearing from one to six of its star-like white flowers on one scape; *Bouvea elegans* (*Calopyranum Gerollianum* of *Schiede*), the bruised leaves of which, mixed with a little water, are used occasionally for killing flies; *Zephyranthes sessilis*; *Sprekelia glauca*; and *Habranthus concolor*; the three latter flowering before the leaves appear.

At AGUAS CALIENTES I found a little more occupation, the rains having then set in; but being still dissatisfied with my excursions, I determined at once to leave the high table-land and proceed to Bolanos, where I should have the command of a vegetation from 3000 to more than 8000 feet of elevation. The town of Bolanos, where I arrived on the 4th of October, is situated in a deep ravine, about 3000 feet above the level of the sea, and from its confined situation has a higher temperature than might be supposed. The thermometer ranges from 39° to 85° Fahr. in the month of December, but in May it is from 49° to 98° Fahr., and even as high as 102° in the shade. The atmosphere being very dry is favourable to the growth of *Bromeliaceous* and *Cactaceous* plants, of which latter there is a great variety, especially among *Opuntias* and *Cerei*. Of the latter there are species which rise to the height of 30 or 40 feet, and yield an agreeable fruit of the size of a large walnut, with red or yellow pulp; they are known under the name of *Pitayas*. Here also occurred a species of *Agave*, with leaves six feet long by four inches broad, from which a spirit is distilled known under the name of *Vino Mescal*. When the plants are of a certain size they are taken up, and the stem, which is about 18 inches long, as well as the leaves, is cut off to the base, which gives the trunk a globular appearance. In this state it is roasted, then crushed, and after passing into the vinous fermentation, *Vino Mescal* is distilled from it. This spirit may be compared to weak whisky, but its strong smoky flavour renders it anything but pleasant. The plant I never could see in flower.

Ascending the steep sides of the ravine on the western side, I left the region of *Acacias*, *Bromeliaceæ*, and *arborescent Cerei*, and entered that of *Oaks*. After a four leagues' ride and constant ascent, I arrived at BEBARENA, the *Mining* Company's wood-cutting establishment, situate in the midst of woods at an elevation of more than 8000 feet above the level of the sea. Here I found, surrounded by evergreen *Oaks*, *Pines*, and *Arbutus denuiflora*, the showy *Befaria mexicana*, forming a shrub of about 6 ft. high, and at the time covered with its large white flowers. The pretty little *Mammillaria senilis* I found on rocks in the [illegible] posed situations; its long white spines, which at [illegible] bent backwards, seem to defend it against [illegible] In the more open places *Lupinus leptocarpus* [illegible] *rensis longiflora*, and *gracilis*, *Castilleia imberbis*, *Lamarckia*.

On the [illegible] were common.

[illegible]ary, 1838, I proceeded from Zacatecas over [illegible]igh table-land to SAN LUIS POTOSI, and thence to the Rancho de los Gallitos. Near San Luis Potosi I found *Berberis trifoliata* in great abundance, forming a shrub 4 to 5 feet high; it was then just coming into flower. The Rancho de los Gallitos, on the eastern declivity of the great table-land in a narrow valley, enjoys a delightful temperature, and is surrounded by constant verdure and noble forests of *Oaks*. It was near this station I found the striking *Berberis Hartwegii*, with its long spikes of flowers and pinnate leaves. This desirable species still remaining to be imported, I shall describe its locality particularly, for its seeds will amply remunerate any traveller that may land at Tampico and proceed to San Luis Potosi or Zacatecas. Before reaching the valley of Los Gallitos, on the ascent from Santa Barbara, there is a black rock on the right-hand side of the road, called "El Contentoso," with a small chapel hewn in the rock, and always gaily decorated with flowers and candles by the passers by; this place is held in the deepest reverence by the Indians, from the circumstance of Nuestra Senora de Guadalupe being said to have appeared to several of them; and they cannot pass this place without paying homage to their protectress saint. It was at the foot of this rock that I found *Berberis Hartwegii*.

I now resolved to leave the arid plains in the north and proceed to MONTELIA, the capital of the state of Michoacan. This country about this town, from its broken surface, presents a beautiful vegetation; in the higher parts Pines and Oaks predominate, and the latter are adorned with a great variety of *Epiphytes*. On the western declivity towards the native village of Jorullo, I found *Pinus occarpa* in great abundance, forming a tree 40 to 50 feet high; of this I secured an ample supply of seeds, but from its low situation, I fear it will not withstand our northern winters. The cones of this Pine, after being ripe, will remain on the tree without opening for two or three years, and the seeds in them are equally as sound as on the first once. In the most elevated parts I found the showy *Fuchsia fulgens* in the greatest perfection, and native of *Bignonia radicans*, bearing its bright scarlet flowers on a scape 8 to 9 feet high. In the more shaded places, the pretty little *Hydrocotyle umbrata*, and *Adiantum microphyllum* were met with. In pastures, *Bromus gamboliferus* and *Cynodon dactylon* [illegible]

After a two months' stay in this [illegible] I started for Acapulco, at which place I arrived after a two days' ride across a mountain road, where I observed fine trees of *Pinus Montezumæ*

and pseudostrobus, the former being called "Ocote-chino," because it abounds in abundance of resin, it yields the best "Ocote," or candlewood; it attains the height of 100 feet, and in diameter 4 feet in diameter. *P. pseudostrobus* also grows in the same elevation, and may be easily distinguished at a distance by its long slender branches diverging at a right angle from the main stem, as in the species of the section *Strobus*. Its chief range is about 9000 ft., while that of *P. leiophylla* is a few hundred feet lower. On an excursion to the "Campanario," the highest point of the mountains of Anganguco, I saw some remarkably fine trees of the "Quamel," or *Abies religiosa*, 5 to 6 feet in diameter, and rising to the height of 150 feet. Its chief range is about 9000 feet above the sea; beyond that elevation its place is supplied by *Pinus Hartwegii*, rising to the height of 40 to 50 feet. With the latter I found *Pentstemon frigidum*, the leaves of which are poisonous to cattle, *Microstylis macrostachya* and *Juniperus mexicana*, the latter forming a small straggling shrub a few feet high.

On the 20th of Oct., 1838, I arrived at Real del Monte, after having crossed once more the high table-land of Mexico; but, as usual, without finding much to reward me. The town of Real del Monte, being situated at an elevation of above 9000 feet, is surrounded by high ground, of which the "Sumate," the highest peak, rises to the height of 9500 feet above the level of the sea, the country around being well wooded with a great variety of *Oaks* and *Pines*. On the eastern declivity of the Real del Monte chain of mountains is the deep ravine of Mestitlan, commonly called "Barranca grande," which from its chalky soil is a favourite haunt for *Cactaceæ*. It is the only habitat of *Cereus senilis* that I am acquainted with in Mexico, the largest plants of which, attaining a height of 24 feet, give the scenery a very singular appearance. On another excursion to the natural bridge called "Puente de Dios" I found *Spiræa parvifolia*, *Quercus petiolaris*, *Lindleya mespiloides*, the latter forming a slender shrub 10 to 12 feet high, and the pretty little *Mammillaria Schiedeana*, which seems quite stationary there, having nowhere else been met with.

On the barren hills of Zimapan, *Pinus Llaveana*, forming a tree 15 feet high, was at this time (November) covered with small green cones, which are two years in coming to maturity; *Berberis gracilis*, with its slender stem and red leaf-stalks, and *Berberis pallida*, have been found at this station, as well as near the hot springs of Atotunilco el grande. In the ravine of Encarnacion I found another new species of *Garrya*, *G. macrophylla*, which from its large foliage is by far the handsomest kind; but, unfortunately, the few seeds I found did not grow. *Juglans nigra* was found in the same locality. Near the Company's farm of "Guajolote" I found several sorts of *Pines*, among which *P. patula*, from its smooth slender stem and valuable timber, particularly attracted my attention. Near the small village of Apulco I found *Berberis lanceolata* and *Pinus apulcensis*, and along the road *Cupressus thurifera* forms a stately tree 120 feet high. From this latter station the descent was very rapid to a place called "El Banco," probably so named in allusion to the bank or ledge of rock over which one has to pass at the imminent risk of falling into the ravine below, in order to reach the small village of San Cornelio. The descent to this place is very interesting; at every step there is some change, the noble *Tree fern* (*Cyathea mexicana*) makes its appearance there; *Lopezia hirsuta*, *Alstonia ciliata*, *Lophospermum scandens*, *Cobæa stipularis*, *Gaultheria nitida*, were all in full flower. It was in company with those that I found the noble *Habrothamnus fasciculatus* of *Schlechtendahl*, the seeds of which I was unable to procure; it was a very fine shrub about five feet high. It has since been raised in Belgium, and a fresh specimen in flower, communicated by Mr. Van Houtte, Nurseryman of Ghent, has furnished, with the assistance of one of my dried specimens, the means of preparing a figure of one of the gayest plants of the Mexican Flora. [A most beautiful thing.]

The valley of Oaxaca is between 4000 and 5000 feet above the level of the sea. The greater part being under cultivation, I resolved to visit the well-wooded heights to the east, which are visible from the town. A ride of five miles over a well-cultivated country, varied by a few patches of sugar cane and cochineal plantations, brought me to the entrance of the mountains, which are thinly covered with *Oaks* of a dwarfish growth, intermingled with *Arbutus jalapensis* and *oaxacana*. *Crataegus mexicana*, *Alnus mexicana*. *Mascagnea antirrhiniflora*, and a species of *Salix* grew along the rivulet. About 500 feet higher, at a hut called the Rancho del Estudiante, *Pinus Teocote* and *Leiophylla* appeared in company with *Cercocarpus Fothergilloides*, and *Tilia mexicana*, the latter forming a lofty tree. In shaded places overhanging the rivulet, *Fuchsia arborescens* was flowering profusely, forming a little tree 12 feet high with a stem five inches in diameter; a shrubby *Bocconia* and *Garrya laurifolia* were also met with. At the "Rancho del ojo de agua," the ascent became more steep, the *Oaks* appearing in larger masses and taller trees, and covered with several species of *Tillandsia* and a few *Orchidaceæ*.

Having reached the "Cumbre" or highest point, there were some stragglers of *Pinus Russelliana* or *Devoniana* which in want of cones I could not distinguish, and some stately trees of *Abies religiosa*. The *Oaks* were no longer clothed with *Tillandsias* and *Orchidaceæ*, but their places were occupied by a brown moss hanging gracefully down the branches in threads nearly three feet long, which gives the trees a singular appearance. *Cornus disciflora*, *Ceanothus azureus*, *Rubus trilobus* with its large white flowers, the pretty little *Cuphea pubiflora* and *Melampodium sumichrasti* were found at that station, the elevation of which above the level of the sea, must at least be 8500 feet. In descending gradually towards "La Parada" which is a kind of inn, the woods consist chiefly of *Pinus Teocote* and *Oaks*. On the latter I found *Odontoglossum nebulosum*, *Cattleya citrina*, and several other species. After passing the bridge, "Puente de Gia," where I found *Eschscholtzia scaniosifolia*, and the village of San Juan, the *Oaks* ceased entirely, and were replaced by small *Agaves* and *Bromeliaceæ*. *Orchidaceæ*, although few in number, no longer cling to trees, but seek their nourishment from the ground; an instance of which is *Epidendrum falcatum* with its thick leaves and brittle rhizoma, which was growing most luxuriantly on a heap of loose stones, and perfuming the air towards evening with its large white flowers. After descending from the village of San Juan to the flats of Santa Ana, and following the rivulet as far as the mine of Socorro, I crossed a high ridge, where mining operations are carried on, and arrived at the Hacienda del Carmen, an establishment for reducing the silver ore. Carmen, or Castrejon, as it had formerly been called, is situate in a deep and narrow ravine, the sides of which are well wooded with *Pines* and *Oaks*, the showy *Arctostaphylos nitida*, *Gaultheria hirtiflora*, *Fascicularia caripensis*, *Arbutus jalapensis*, *Lycnia ferruginea* and *Philadelphus mexicanus*. Ascending the steep sides on the right I arrived on the "Monte Pelado" or bald mountain, so called from the upper part being destitute of trees, which gives it a singular appearance compared with the mountain ranges on the opposite side of the ravine. Near "Las Cruces" on the ascent to the Monte Pelado I observed some remarkably fine trees of the *Abies religiosa* and *Pinus Ayacahuite*, the latter measuring three to four feet in diameter. Bordering on the limits of trees I found three plants remarkable for their geographical distribution; they had previously been known from other countries; they are *Chimaphila maculata*, *Pyrola rotundifolia* and *Ilex Aquifolium*, the latter found by Humboldt near Ibarra in the Andes of Quito.

Having well examined the vegetation about Carmen, I ascended the high ground at the back, crossed Llano verde and arrived at the Indian village of Tuneton. The name of Llano verde (green plain) is given to the mountain intervening as far as Tuneton, a distance of eighteen miles, and is derived from a green swampy plain in the middle of the wood, measuring some twenty feet square. The climate of Llano verde is termed by the natives "caliente humido," or warm and damp, the temperature being about 70° Fahr. and particularly adapted to the growth of *Cunilleæ ovalifolia*, which I found there in great abundance. In the more elevated parts *Pinus Ayacahuite*, *Pinus Montezumæ*, several *Leguminosæ*, *Pteris aquilina*, *Asplenium Trichomanes*, *Cheilanthes mexicana*, with both yellow and brown-edged fronds, and *Cystopteris fragilis*, covered the mountain sides, while the rocks, almost inaccessible, except to the mountain goat, were covered with *Echeveria secunda*, *Sedum Cepæa*, *Cotyledon laxa*, *Mammillaria Schiedeana*, and *Cheilanthes myriophylla*, the latter with its bright scarlet flowers, were growing on the summits of the wood. From Tuneton I went over a broken road to Tabaa, where I found *Begonia lævis* and *discolor* in full flower, growing in company with *Magnolia glauca*, the flowers of which are used by the religious Indians in decorating their places of worship. Tabaa, being situate in "tierra caliente," or the warm country, produces some fine *Pine apples*, *Oranges*, *Plantains*, *Sugar-canes*, *Cherimoyers*, and *Coffee*. Descending towards Santa Gertrudis I found a small bean, the seeds of which resemble those of *Abrus precatorius*, and are said to be employed with success against the bite of the little venomous spider called Chintatlahua.

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSES, CONSERVATORIES, &c.

The time for potting plants has now arrived, and the greatest care is necessary in the selection of proper composts for different families. Good friable loam, fibrous turfy peat, leaf-mould, and sand are the proper materials from which composts for all kinds of plants may easily be made; one-third peat, one-third leaf-mould, and the other third of loam and sand, will make a suitable compost for young plants of nine-tenths of those in cultivation. Older plants will require the proportion of peat lessened, and that of the loam increased; sandy peat alone is used for Heaths, Epacrises, and such like; but the more robust of these and all the Chinese Azaleas, ought to have one-third leaf-mould added to their compost. Two-thirds loam, and one-third leaf-mould, charcoal, and sand, is a good compost for Orange-trees, Neriums, and many other strong woody plants; charcoal and ground bones make the best of drainage for all plants, and a greater quantity of them may be used in that way than of pot-sherds; thus making the drainage more efficient, and yielding a great store of nutriment for the more active roots. The day temperature may now be up to 80° with sun heat, but not above 60° at night. The paths should be sprinkled over occasionally on fine days, and the atmosphere of all the houses should be kept more moist for the future.

Conservatory.—Old-established specimens in this house need not be potted for the next six weeks. Old plants in general, do not require to be so early potted as the young portion of the collection. The varieties of the Chinese Primrose are very useful from September to May, on account of their flowering so early in the autumn; a small quantity of their seeds may now be sown, and three more sowings of them, made in April, May, and June, will carry on the succession. Mr. Latter, the great Cucumber grower, is also an excellent grower of these winter flowers; he uses leaf-mould only, in which they grow and flower better than in any compost; cuttings made now from forced Anne Boleyn Pinks, will be ready to be planted out by the end of April and May; as will also cuttings of other Pinks and Picotees now in forcing. Be careful of Bulbs. When they have done flowering, the best plan is to turn them out of the pots and plant them in a cold frame in any light soil: afterwards they come in useful for spring flowers in the borders. Sitting-rooms are destructive to most plants; endeavour to change the plants in them as often as convenient, and keep up a large stock of those most preferred for this purpose.

Greenhouse.—to on potting the younger portion of these plants, and see that such as are growing too fast are removed to a cool situation.

Forcing-Pits.—Gardenias and young Orange-trees, forced for their blossoms, will now require a strong moist heat of 75°, with a bottom-heat from 80° to 90°. Many of our common border-plants will force from this time, if taken up with balls, potted carefully, and kept in the shade the first week. Common Auriculas and Polyanthuses will answer well in this way; leaf-mould is the best material for them under this treatment. The Evergreen Berberises are good plants for forcing, and they are much sweeter when they are forced. Daphnes do not like leaf-mould so well as poor sandy loam, in which they will force easily; all the herbaceous Paeonies will force in pure sand, or any refuse soil from the potting-bench, and they require no preparation beforehand. Seed-pots should never be exposed to the sun till all the plants are up; many seeds that are difficult to vegetate will come up easily in perfect darkness, but all should receive some bottom-heat.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

In the Flower-garden many of the spring Bulbs will now be showing bloom; it will therefore be necessary, on a dry day, to hoe the beds over, so as to freshen them up, and make them a little neat. After the late frost the lawn should be raked over with the daisy-rake, to clear the grass of worm-casts or stones, and be rolled with a heavy roller at least once a week. Where the grass is coarse it is a good plan to have it mown, cutting it close to the ground at this season, and where the herbage is thin or does not "cut well," a little Dutch Clover-seed should be sown and afterwards thinly covered with some rich soil. To those parts of the lawn which soon burn up in dry weather, apply a dressing of wood-ashes and soot with a little sand, or if more convenient, give a good soaking of liquid manure. Relay or repair Box edgings and Grass verges, so as to have everything ready for trimming the walks, as soon as the weather is favourable.

Rosery.—Most of the hardy Roses being now pruned, the beds may receive their spring dressing. Night-soil is said by Mr. Rivers to be the best manure to use, and if disinfected it is not objectionable, but if not disinfected it will be better to trust to the drainings of the dung hill, or to a dressing of Potter's Guano, superphosphate of lime, or Lance's Carbonated Humus. Plants that were much infested with green-fly last season, may be cleared of the eggs of that or any other insect, by syringing them with water, at the temperature of 150°, or by painting them over with lime, soot, and cow-dung, mixed to the consistency of thick paint with strong soap-suds. This is a certain remedy.

Pits and Frames.—The plants here, which hitherto have been kept quite dry, may now receive a gentle watering on some sunny morning, and be encouraged to grow a little; give plenty of air in the daytime, but cover securely at night. Proceed with the potting of autumn stock plants, and the pricking out of tender annuals, which should always be attended to before they become crowded in the seed-pots, and encourage the plants afterwards in a close gentle heat until they are established in the new soil. Pot Tigridia pavonia and conchiflora in light turfy soil, putting two bulbs into a 48-sized pot, and placing them in a warm frame or forcing house until they begin to grow. Make a sowing in heat of Œnothera macrocarpa and taraxacifolia, two exceedingly useful plants, which flower beautifully in the autumn, if sown at this season. Stop scarlet and other Pelargoniums intended for planting out, so as to make them bushy.—*W. P. A.*

III.—FLORISTS' FLOWERS.

But little progress has been made during the past week in the Florist's department, owing to the extreme variableness of the weather, the very fickleness of which requires renewed vigilance on the amateur's part.

Florists who have not laid in a sufficiency of plants in the autumn are now thinking of purchasing. The following Auriculas are good sorts for competition, and ought to be in every collection. Green-edge:—Page's Champion, Pearson's Banajee, and Obl. Taylor. Gray-edge:—Waterhouse's Conqueror of Europe, Ringleader, and Lovely Anne. White-edge:—Taylor's Glory, Lord of Hallamshire, and Ashworth's Premier. Selfs:—Dixon's Apollo, Barker's Nonsuch, and Metropolitan. All air must be given when possible, but not if the winds are cold; then tilt the lights.

Protecting mats ought to be procured without delay. The following may be relied on as good show-flowers:—Pearson's Alexander, Page's George the Fourth, Bullock's Leader, Mather's Earl Grey, Lord Ranelagh, and Crowshaw's Invincible.

Ranunculuses.—The seed must be kept moderately moist, by dipping a brush in tepid water and, drawing the hand over it, cause the drops to fall lightly, so that the soil covering it may not be displaced.

Carnations.—Make ready for potting, get the compost under cover the first fine dry day, it being very injurious to the layers to pot them in soil that is too wet.

Picks.—Try to grow some of these in large pots, mixing a little rough charcoal with the soil; they will well repay the trouble.

Pansies.—Pinch off the leading shoot, to make your plants "stocky;" it will prevent the mortification of having them broke over, at the surface of the bed. Top-dress with rotten manure. Potter's Guano has been used with success, "but be careful, do not poison your plants with too much of a good thing."—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—There is much difference of opinion about plunging out Pines, and those who would like to convince themselves of the best mode of culture would do well to plant out now, at one end of a pit (heated below by tanks) a few good plants of the Queen and Montserrat, and afterwards to compare the growth of the plants, size and quality of the fruit so treated, with the growth and produce of plants grown in pots in the same pit. I name the Queen and Montserrat for this experiment, as they fruit sooner than many others. The recently potted Pines will require no water for the first few days after potting, unless the soil was dry when used, in which case give a gentle watering. If the watering has to be done from the outside of the pit, choose mild weather for it. Continue to shade during sunshine the plants that were disrooted, using thin bunting or woollen netting.

Vinery.—Vines having their roots inside the house, if the border is the least dry, will require watering; do not be guided by the appearance of the soil on the surface, but examine it nine inches or a foot deep. Add fresh litter to the covering outside, to keep the heat regular. Increase the temperature of the second house to 55° at night, gradually rising, when the buds have all broke and the "shows" have begun to appear.

Peach-house.—Continue the temperature, where the early Peaches are swelling, at 55° or 57° by night during cold nights; they will bear 60° by night during mild weather. Tie in the young shoots nearly parallel with those they proceed from: much of the beauty of a fan-trained Peach-tree depends on the early and careful performance of this. Increase the temperature of the second house gradually to 55° by the time the fruit is fully set.

Cherry-house.—Do not increase the temperature till the fruit begins to ripen, when a few degrees more heat may be maintained. Be careful to use clean soft water in syringing, that the fruit may be perfectly clean when ripe. Attend to watering and keeping the trees free from insects.

Melons.—Much attention will be required to keep the heat in the frames regular; owing to the nature of the heating material, the temperature will vary with the changes of the weather; aim at having 70° of heat by night. Cover with double mats when mild, and keep up the heat during cold or stormy weather by additional covering on the glass and lining. Prevent cold gusts of wind from entering when air is given, by placing slips of bunting or woollen netting over the open space. Stop the plants in frames above the second leaf.—*G. F.*

State of the Weather at Chiswick during the last 18 years, for the ensuing Week ending March 9, 1844.

Mar.	Aver. Highest Temp.	Aver. Lowest Temp.	Mean Temp.	No. of Years in which it Rained.	Greatest quantity of Rain.	Prevailing Winds.							
						N.	N.E.	E.	S.E.	S.	S.W.	W.	N.W.

Average		29.810	29.651	49.7	33.4	41.6		1.11

Feb. 23. Clear, with sharp frost; lightly and uniformly overcast; boisterous, with heavy rain in the evening.
24. Clear and foggy; cloudy, clear and frosty; rain.
25. Rain; equally, with showers; slightly clouded and fine.
26. Heavy clouds and showers; barometer exceedingly low: sunshine and showers alternately; half-shower half-past 1; boisterous with rain.
27. Clear and frosty, with very slight sprinkling of snow and hail on ground; clear, cold, and dry.
28. Clear and cold: fine, with sunshine; cloudy and fine.
29. Slight frost; clear and very fine; rain at night
Mean temperature of the week, 0.3 deg. above the average.

Notices to Correspondents.

Gardeners' Chronicle.—The first Number of the present year has been reprinted, and may now be had. The newspaper part has been omitted.

Communications from the following Correspondents are in type, and are only waiting till room can be found for them:—*W. R., J.C.X., E. Bevan, M.D., A. Pettigrew, P. P., W. Billington, M. G., J. B. K. L., J. Wighton, E. J., A Visitor, J. L. Snow, W. B. Booth, A Subscriber, J. Brown, G. Thompson, Vitis, A Practical Man, Peter Mackenzie, Quercus, R. Errington, Gr., J. M'I., J. Spencer.*

Aponogeton distachyon.—*Alpha.*—I have grown this plant for several years in a small pond at Stoke Newington, and have had flowers sometimes within a week of ice being on the surface of the water. It is necessary to plant it below the influence of frost, but not deeper, as, if too deeply planted, it will not be able to reach the surface, on which its long leaves float. It blooms freely here all the winter months in a shallow tank in the greenhouse, where, on account of its fragrance, it is a great favourite. It seeds freely, and every season produces a numerous progeny of self-sown plants.—*J. B.*—It grew and flowered freely from February till June, in an aquarium formed in a sluggish brook, with a calcareous mud-bottom, from about 1834 to 1840 (when the informant quitted the premises) at Stoke Bishop, in Gloucestershire, and since that, in a pond made with plastic clay, with the superior lining of chalky loam, at Ashby, in Hampshire, till devoured by sheep.—*Anon.*

Arnott's Stove, imitated in fire-brick, is set up in a small greenhouse; the fire is regulated by a valve of easy control, and will burn 12 or 14 hours without attention. The only defect in the stove, is the difficulty of finding a cement that will stay in those joints of the brickwork nearest in contact with the fire: these open joints invite a capricious admission of air, destroying the control of the valve, hindering the continuance of the fire, and influencing the degree of heat. Perhaps some of our kind readers can suggest a cement that will help the dilemma of a subscriber.—*P.*

Asphaltic.—*A Subscriber.*—We do not know whether the mixture made of grouting this has been exactly followed, to report on the subject having reached us. But we do know that the application of very strong manure, in the manner described by Captain Chesshill, has been very advantageous. Common Guano, mixed with sea-salt, and applied in a liquid form, has proved most beneficial.

Asphalte.—*Nhel.*—We do not think sea-sand can be employed in making asphalte floorings and paths, because there is no getting it dry, and perfect dryness is indispensable to the success of the operation. One inch thick is not enough. We do not see why lime rubbish should be injurious; we know it, on the contrary, to be advantageous. You may apply gas-water to your Peach-trees safely now.

Books.—*William.*—We agree with you that gardening books are often too dear. Booksellers will allow gardeners some discount for gardening books, if they apply to the publishers of them. We, however, cannot interfere in such matters.——*A Subscriber.*—Your question is quite out of our line. You had better consult the foreman of the nearest brewery.

Brachycome iberidifolia.—*Clericus.*—Seeds of this should be sown in pots or shallow pans filled with light rich soil, and well drained. The pots should be plunged in a gentle hotbed. In order to obtain blooming plants early, the seeds may be sown now; but if that is not an object, a fortnight or three weeks hence will be better; as soon as the young plants are up they should be potted into small pots, and if they are to be kept in a greenhouse, shifted into larger ones as they require it. Those that are to be grown out of doors should be planted out into prepared bed early, say by the end of May, in order that they may perfect their seeds in September or early in October.‡

Bugs.—*J. W. K.*—Would be obliged for information as to the success that has attended the use of Bagster's hives.

Carnations and Picotees.—*A Reader of the Chronicle.*—Neither the aspect nor the opaque roof will suit Carnations and Picotees; they require plenty of light when coming into bloom. We recommend you the following sorts:—*Scarlet Bizarres:* Twitchett's Don John, Martin's Splendid, Headley's Wm. Cobbett, Rainsforth's Gameboy, Roi de Capucin, Ely's Lord Durham. *Crimson Bizarres:* Puxley's Prince Albert, Holmes' Count Paulini, Cartwright's Rainbow, Ely's Duke of Bedford, Strong's Lionsmo, Ely's Lord Milton. *Purple Flakes:* Mansley's Beauty of Woodhouse, Millwood's Premier, Nix's Lady Chetwynde, Strong's Esther, Lascelles' Queen of Sheba, Hogg's Colonel of the Blues. *Scarlet Flakes:* Chadwick's Brilliant, Maud's Rowton, Wigg's Earl of Leicester, Simpson's Marquess of Granby, Willmer's Hero of Middlesex, Gresaly's Mary Anne. *Rose Flakes:* Brooks' Flora's Garland, Wilson's Harriet, Ely's Lady Ely, Willmer's Endymion, Fletcher's Duchess of Devonshire, Sidemouse's Lady Rowley.*

Celeriac.—*P. T. O.*—Should be raised like Celery, and similarly managed, till fit for planting out. It should always be divested of side-slips. It requires rich sandy soil, in which it may be planted out, shallow, in the beginning of June, the plants being 15 inches apart. It must not be earthed up.‖

Cucumbers.—*A Subscriber.*—A thermometer plunged into the mould of the bed, about three inches deep, should indicate 80° of heat, which is a safe temperature for the plants.‡

Datura, &c.—*An Irishman.*—Presuming that your Datura is D. arborea or sanguinea, it requires the following treatment:—Being large plants, growing to the height of 10 or 12 feet, they flourish best when they are planted in the bed of a conservatory; but they will also grow well in large pots. The soil should be a mixture of peat, loam, and sand, with a little leaf-mould. They do not succeed well when planted in leaf-mould alone, which is, no doubt, the cause of your plant becoming sickly. Brachysema latifolium is an abundant bloomer, and grows freely in peat, loam, and sand, with the addition of a little rotten dung. The same kind of soil will also suit Hovea Celsi, which should be kept in a light and airy part of the greenhouse, and potted and watered with care. To render it bushy, the main shoot should be topped when the plant is young, and the young laterals should also be shortened in when they begin to grow, for if this is not attended to the plant is particularly liable to grow up tall and naked at bottom.‡

Dauccus.—*P. T. O.*—A dwarf variety of Fennel. It will grow in any rich light soil. Sow in drills, and blanch the young shoots by earthing up. It will not do *well* without bottom-heat.‖

Fruit-trees.—*Abdulcaymus.*—Your Apples and Pears are for the most part subject to canker. They are old varieties. Your soil has doubtless its share in causing the disease; but you had better get new kinds. If you cannot procure fresh rich loamy soil, the *sward of any soil* will certainly prove beneficial. We would still advise you to cut away all unsound wood. Lime will be best applied, in a quick state, early in spring. It should be spread over the surface of the ground, and dug or forked in so as not to injure the roots.‖

Gold-fish.—*C.*—The Gold-fish is a species of carp, and all these fish deposit their spawn on weeds growing on the shallow sides of ponds most exposed to the influence of the sun. The common-pond weed, the Water Ranunculus, and the coarse Grasses which float on or near the surface, are the most favourable for this purpose. An artificial pond, 30 feet diameter, of an inverted conical form, 4½ feet deep in the centre, and composed of stone and mortar, is most probably too deep at the sides for the spawn to be hatched, even if the weeds above mentioned are in the pond. If the sides are shallow the common Forget-me-not would afford the proper means for the fish to deposit its spawn on the stems; and other plants that are ornamental may be found to answer the purpose; but without a shallow side it is likely that the spawn, by not receiving sufficient warmth, would perish. Fish are male and female. The female deposits the ova or hard roe, and the male then deposits the milt or soft roe on the ova, without which latter process no vitality ensues. Water-lizards might eat some of the spawn, but unless they were in great abundance it is not likely they could destroy the very large quantities of spawn which the female fish in a healthy state usually deposits. *B.* [There is a book by Bocclus "On Fresh-water Fish;" and Mr. Yarrell's "British Fishes" is a classical work.]

Grasses.—*Paris.*—For the purpose of distinguishing Grasses take "Parnell's Grasses of Scotland;" for their qualities, "Sinclair's Hortus Gramineus Woburnensis;" for systematic questions, "Kunth's Enumeratio." They are all cheap books.

Greenhouses.—*A. B.*—Nothing will grow in an old-fashioned hibernatory with an opaque roof and high front sashes; but many things will live in it through winter without growing. For growth, light in abundance is requisite. If you take off the roof and replace it with glass, then Camellias and Orange may succeed in it in the open ground.

Heating.—*Hants.*—We find earthenware pipes break at the joints, and we understand that this always happens; but we are told that if the flaws are made good with cement, they will do very well afterwards. You had better use hot-water gutters, constructed as recommended at p. 699, 1842, and covered with slate.——*H. D.*—No doubt gas had distilled from the coals during the night and had exploded. This is *one* of the nuisances attending smoke flues. We would rather not have a greenhouse at all than heat it by smoke flues.——*Cirrus* will probably find his purpose answered by a plan of a Melon-pit that will be published next week. Cut down your Vines to three eyes, and enrich with bones and good stable-dung; it is immaterial whether they are started in heat or not. Mr. Roberts's directions are very good, and it is a great pity you cannot cover your border with stable-litter. Perhaps you can keep off the cold rain of spring by boards or some kind of contrivance. You can force vegetables and Strawberries in your pit; but it will not suit Greenhouse-plants where the Vines cover the glass.——*J. H.*—When you are afraid of expense it is difficult to do what you want. The best way for you to proceed would be to get a set of Bullivant and Bailey's iron rafters; but if they are too dear, then you must have recourse to hot-water brick-gutters, which will not be dangerous if covered with slate. For the greenhouse and you had better trust to the flue of the fire-place which heats the tanks. We quite agree with you that all the boilers yet manufactured are far too expensive for many little operations. Can't you get an iron saucepan set in brickwork and pierced for a flue and return-pipe? It would do very well.

Hyacinths.—*Amen.*—We cannot explain your case, which, in the way you state it, is unaccountable.

Inscriptions.—*A. O. M.*—We know of no application likely to clear away from the surface of a very old rough-hewn limestone slab the incrustations of Lichen, &c., now rendering illegible a supposed inscription, except the strongest possible solution of caustic potash; and we are not sure that it would succeed. It is, however, worth trying.

Insects.—*Ellesmach.*—As there are many caterpillars which attack fruit-trees when they break into leaf, we cannot tell what species it is that you suffer from, but if you will send us specimens when the larvæ make their appearance we will give you the best information in our power. It may be the caterpillar of the winter-moth, Phalæna (Hybernia) brumata, whose history you will find in vol. i., p. 812, with figures, and the best mode of arresting that pest. *R.*——*A Young Gardener.*—The curious rings of eggs from the branches of fruit-trees will produce the caterpillars of the "Lackey-moth," which spin a web, and are very injurious in orchards and hedges, where they abound to a great extent. See vol. iii., p. 244, under the name of Bombyx Neustria. *R.*——*A Constant Reader.*—Train-oil is an excellent application for your Apple-trees. See last week's *Chronicle*, p. 116. *R.*——The beetles communicated by *Professor Royle* feeding upon Cayenne pepper, are a species of Anobium called Leloderma testacea, which inhabits South America as well as the East Indies. The application of heat, either by baking or immersion in boiling-water, would destroy the insects; and if the bottles be made of cast glass, this process will be attended without loss. The East Indian Wheat has been eaten by a Weevil named Calandra oryzæ, from its depredations on the Rice. It is closely allied to C. granaria; see vol. iii., p. 907. *R.*

Lawns.—*A Novice.*—On 1¼ acre of new lawn you may sow the following grass-seeds, viz., Festuca duriuscula, 4½ lbs.; F. tenuifolia, 3 lbs.; Cynosurus cristatus, 7½ lbs.; Avena flavescens, 1½ lbs.; Lolium perenne, 30 lbs.; Poa nemoralis, 2 lbs.; P. sempervirens, 2 lbs.; P. trivialis, 2½ lbs.; Trifolium repens, 11 lbs.; and T. minus, 3 lbs. This is a sufficient quantity to cover the ground closely in a short time.‡

Larkspurs.—*A Subscriber.*—These will succeed in almost any soil; but a rich friable loam and a situation open to the sun suit them best. They are improved by adding thoroughly rotten manure freely to the soil in which they grow. The seeds of the annual kind do best to be sown in autumn, as when they are sown in spring it is late in the season before they flower. It is probable that your young plants of these are eaten off by slugs, with which you say your soil swarms. These may be effectually destroyed by applying pretty strong gas-water to the ground at their feeding time; but it must be clear of plants.‡

Melons.—*Theta.*—If you will again refer to the article on the Cultivation of the Melon, on January 27th, you will find it there stated that one plant was planted under each light, from which two shoots were trained up the trellis, and about three Melons were allowed to swell off in the same space; that is to say, that the average number of Melons grown on each plant was three. With regard to your second question, the layer of dung and leaves at the bottom was firmly trodden, but the soil was only pressed with the hand round the sides of the pit, and not trodden; because treading makes it liable to crack when it becomes dry, and the roots are thereby severed from the plant. If your soil is light and dry when it is put into the pit, you may tread it with advantage. There are many little matters necessary to be observed in the cultivation of most plants, upon which it is difficult, without going to a great length, to give directions which shall be applicable under all circumstances. It was the Hoosainee Melon which was grown at Trentham last year. The seeds were obtained from a distinguished cultivator six years since, and were, no doubt, true at the time. Since then, notwithstanding the pains that have been taken to prevent it, it is possible that it may have become impregnated with the Ispahan. If it has become so crossed, it is probably not the less valuable on that account. At all events, I consider that the flavour was as good last year as when I first had it; and there was no other kind grown near it last year. I cannot assist you in obtaining the Sirdar Melon, having only now been able—and that through the kindness of a gentleman in Ireland—to obtain two seeds.—*G. F.*

Manures.—*W. T.*—We fear sulphate of soda will not prove a good manure. Experiments are not in favour of it. If used at all it had better be mixed with the dunghill at some such rate as two stone to a ton of the dung. Sulphate of ammonia should be applied in March at the rate of 2 or 3 cwt. per acre. Its effects are very powerful but transient.——*R. H. C.*——Give a wine glass of superphosphate of lime to each plant of Pelargonium when prepared for flowering. Potter's Guano is an invaluable manure. Use it as a top-dressing at the rate of 3 lbs. to a rod.——*Monmouth.*—As gas-water varies in strength, no exact quantity of sulphuric acid will fix the ammonia. Add the acid, a little at a time, till effervescence ceases, and then the fixation will be complete. Experiment serves to show that March is the best time to apply gas-water, &c. to grass-land. Applemust has a bad reputation as a manure, and is only fit to be fermented in a dunghill. No means are known of preventing the death of branches of the Moorpark Apricot.——*T. B. C.*—Guano may be applied before the seed is committed to the ground, but it must be mixed with a large quantity of soil or it will kill the seedlings. The best way of applying it is mixed with water, poured between the rows of plants as soon as they are fairly above ground.

Morphology.—*K.*—Is it fair to criticise "R.E." before he has stated his case? If his arguments can be refuted, we shall be very happy to insert the refutation, when he has closed the subject; but we confidently expect that no sensible and well-informed a man as you are, will be a convert before then.

Names of Fruit.—*S. S. S.*—Your Pear is the Virgouleuse.‖

Names of Plants.—*Silex.*—Mammillaria tenuis.——*C. D.*—The Trymalium is odoratissimum, and is from Swan River. The Epidendrum is very like tonosumum; but if it *really* is from the Organ Mountains it must be new. We cannot, however, take for such a fact the authority which gave you the Cape as the native of the country of the Trymalium. The colour of Centradenia is more or less pink, but the term red is not strictly applicable to it.——*S.*—Erica herbacea.——*C. C.*—1. Some Hedychium. 3. Lotus Jacobæus. Others not in a state for determination.——*J. Mel.*—It is impossible to name a plant from a leaf and a sketch, unless it is something well known. Perhaps it is some Cæsalpinia.——*C. H. N.*—1, some Viburnum, perhaps. Fragments out of leaf and flower cannot be named.¶——*W. S.*—1, some Thuja; and 2, some Juniperus, but they cannot be determined from such fragments; the latter resembles J. phœnicea.——*J. S.*—1, Calceolaria pinnata; 2, Pyrus pinnatifida; 3, Crataegus torminalis. The ignorance of natural history of people who write books of travels is disgraceful. Opobalsamum is produced by Pistacia gileadensis; Nabbutch is a name we don't remember; Valonia is Quercus ægilops; the prickly Oaks are —— anything.——*A Young Gardener.*—Araucaria imbricata, Gaidia serioea.

Pansies with Diseased Leaves.—*C. E.*—You would oblige us by sending more specimens of your Pansy leaves, and say whether the variety from which they are taken is a seedling; and whether the disease is confined to this particular sort, or if others are affected in the same way. What is your compost?*

Picotees.—*A Reader of the Chronicle.*—*Red-edged*—Sharp's Duke of Wellington, Brinkler's Masterpiece, Gidden's Tenier, Sharp's Criterion, Wood's Queen Victoria, Brinkler's Duchess. *Purple-edge*—Dickson's Trio to Cambridge, Sharp's Invincible, Gidden's Miss Hennell, Brinkler's Purple Perfection, Ely's Grace Darling, Mrs. Hemmingway. *Rose and scarlet-edge*—Kirkland's Squire Annesley, Gidden's Queen Victoria, Wilson's Miss Fanny Irby, Garratt's Lady Decre, Beauty of Hemmingford, Sykes's Eliza.*

Pits.—*S.*—We recommend the pit figured in the *Chronicle*, at p. 593, 1843, known by the name of the Heckfield pit, as excellent, when stable manure *must* be used.‡

Polyanthuses.—*An Old Subscriber.*—Pearson's Alexander, Buck's George the Fourth, Cox's Prince Regent, Clegg's Lord Crewe, Hufton's Lord Ranelife and Squire Ray, Ackersley's Jolly Dragoon, Nicholson's Gold Lace and Bang Europe, Fletcher's Defiance, Crownshaw's Invincible, and Clegg's Lord John Russell. We do not recommend particular Nurserymen or Florists.*

Roses.—*R. C. W.*—Your China, Tea-scented, and Bourbon Roses may be pruned when the coverings are removed, cutting well back the strong shoots, and taking out the weak ones entirely; at the same time all dead wood or unsightly stumps should be cut neatly out, leaving the young shoots thin and regular.‡

Seed-saving.—*Expanse.*—We hardly understand your question. If seeds are to be saved quite pure, care must be taken to prevent the flowers being hybridised by those of other varieties of the same species: and this is done by setting the flowers artificially or by covering the blossoms with muslin, while expanded, and until the seed-vessels begin to swell. Some seeds, however, are not very prone to hybridise, especially Celery, Endive, Leek, and Carrot; but Beet, and all the Turnip, Radish, and Cabbage races are sure to do so in the absence of precautions. Once transplanting after the plants are full grown is often enough.

Strawberries.—*C.*—Strong young plants with good balls will fruit this season. Canterbury Bells will not bloom the first year, unless sown very early, nor will plants of Alstrœmeria.‡

The Fastolff Raspberry.—*Fair Play* must excuse us. We have already stated, on his authority, what the history of this variety is, and thus due honour is given to those by whom it was raised. We do not find that Messrs. Youell pretend that they raised it themselves. If other people wish to sell it they must advertise it; if not, why complain? We never insert attacks upon individuals, unless for some very grave reason; and here we see no reason at all. To print an anonymous imputation without finding room for a reply, would be anything but fair play, and our columns are intended for something better than disputes.

Tomatoes.—*P. T. O.*—Should be sown in March, in pots, and placed in gentle heat. The plants should be shifted into larger pots, as they require, till the end of May. They may then be planted out in a warm situation, and kept supported from the ground. When a moderate quantity of fruit has formed, the plants should be stopped, and no more fruit allowed to appear, for in this climate only the earliest formed acquire maturity. Regulate frequently in order that the plants may not be deprived of much foliage at any one dressing.‖

Wheat-splitting.—*Tassel.*—The observations already made upon this subject in our columns have led to some, and we hope to many, such experiments as you propose. It is not worth renewing the subject till the result of those experiments shall be seen.

Yeast.—We have to thank two or three correspondents for communications on this subject, which we shall publish, if they prove useful upon trial.

Miscellaneous.—*A. B. C.*—Seyssel asphalte is made by a company. We do not know what its composition is. You may raise Deodars in the same way as Larch, or in many other ways. See our volume for 1842, p. 159. If you have failed it is probable that your seed was bad.——*A. F.*—Your Evergreen Oak will shoot again if cut down; the operation should be performed as soon as the buds are beginning to swell. It is not *very* unusual for Pear buds to bear fruit the first year after insertion; but it usually spoils the bud.——*H. B. J.*—Plant your Arrow-root in light peat and loam, give it *plenty* of pot-room, plunge it in a bottom-heat of 80° or 85°, and keep it damp while growing, so as to drive off red spider.——*Candlestpulus.*—Your distances are proper for Cedars of Lebanon, but too great for Araucarias, which do not spread very much laterally; ten yards are enough for them.——*Flora.*—Commelina coelestis is the only one of your plants that will flower with any certainty the first season.——*A Gardener.*—Worms may be killed by watering your ground with weak gas-water, or lime-water, or a very weak solution of corrosive sublimate. The kind of Kale known among gardeners by the name of Curled Kale is suitable for a private garden.‡——*W. M.* will find an article on the destruction of rats given in No. 46, 1843. A common way of frightening birds from kitchen-garden crops is to set up sticks having Potatoes stuck full of feathers attached to them by means of a piece of twine, in order that they may be moved by the wind.‡——*A Subscriber* is answered in last week's Paper, p. 129.‡——*A Subscriber* should refer to our columns, where the prices of netting are advertised. We never recommend dealers.‡——*S.*—You may plant your Cape bulbs now, and keep them from frost.‡——*A. W. B.*—Thanks. We will attend to it.——*Hereford's* Letter is sent to Mr. Moorman.——*Anon.*—An Ellis's microscope, with knives, &c., complete, may be had for the sum you mention; and it is the most useful one we know of. The book you inquire about will not be republished in less than a twelvemonth. "Paxton's Botanical Dictionary" does not contain the names of weeds. To purchase the books you name would be of no advantage to Mrs. Loudon.——*J. H.*—We believe Mr. Hope is correct in his statements respecting Gas Tar; but we have not tried it. Its vapour would probably be deleterious to plants in leaf.——*Oudeton's Letter* is sent to the London Committee.——*J. W.*—The wood is impregnated with iron, not copper. The colour is curious. The infiltration seems to have taken place since the wood was separated from the parent tree.——*A., Watford.*—A full Index is always given at the end of each year, as you may see by referring to previous volumes.——*A. P.*—Your Pines are certainly in a woeful state; but it is impossible to say why, without seeing them. It *may* be the iron.——*A Journeyman Gardener.*—Much obliged, but we have no use for the volume.——*M. D. T.*—Pray send your address.

SEEDLING FLORISTS' FLOWERS.

Camellia.—*J. K.*—Your seedling is a promising flower; but having bloomed it under such disadvantages, the probability is that the defects in it may arise from that circumstance, and the flower may be much improved another season, under better treatment. It is of a good size, pleasing colour, the petals well formed, and of good substance, with the centre well filled up; this part of the flower, however, is the distinctive part, from the petals being so much crumpled and imperfectly marked. If better cultivation will not remove this defect, it will be of little use.*

Cineraria.—*M. G.*—As far as we are able to judge from the remains of a single bloom, much mutilated, your seedling promises well; the white is pure, the flower large, and of good substance.*

*** As usual, many communications have been received too late.

Erratum.—In last week's Paper, p. 118, col. 4, line 17 from the bottom, for "crevices in the bank," read "crevices in the bark."

EXAMPLE FARM.

WANTED, to Rent on Lease, for a term of not less than 21 Years, to enter at Lady-day, a Commodious Dwelling-house, and about 120 Acres of Arable Land, for the purpose of forming it into an EXAMPLE FARM. It must be near to a Railway station, and within 40 miles of London; on the greensand formation, under the chalk, or on the London clay or Plastic clay above the chalk.—Apply to Mr. MORTON, Chesterhill, Stroud.

FARMS TO BE LET IN THE ISLE OF WIGHT:—

FORELANDS, at BEMBRIDGE, in the Parish of BRADING;

Containing:—Arable			220a.	2r.	33p.	
Meadow and Pasture	26	1	15	a.	r.	p.
Homestead, &c.	2	0	15—248	3	22	

TAPNEL FARM, in the Parish of THORLEY;

Containing:—Arable	344	1	39			
Meadow and Pasture	73	1	2d			
Down	50	0	29			
Homestead	4	0	6—472	0	24	

CHESSELL, in the Parish of SHALFLEET;

Containing:—Arable	267	1	6			
Meadow	6	2	30			
Pasture	10	0	4			
Down	70	2	23			
Homestead	2	2	22—357	1	14	

BARTON FARM, in the Parish of WHIPPINGHAM;

Containing:—Arable	350	0	12			
Meadow and Pasture	71	2	38			
Homestead	7	2	14—429	1	14	

For Particulars and to treat for Lease apply to Messrs. H. and R. B. SWELL, Newport, Isle of Wight.—Feb. 24, 1844.

The Agricultural Gazette.

SATURDAY, MARCH 2, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

WEDNESDAY, Mar. 6	Agricultural Society of England. Highland and Agric. Society.
THURSDAY, Mar. 7	Agric. Imp. Society of Ireland.
WEDNESDAY, Mar. 13	Agricultural Society of England.
THURSDAY, Mar. 14	Agric. Imp. Society of Ireland.

FARMERS' CLUBS.

March 6	Wickham Market. Tenford. Wenlock. West-Hereford.	March 5	Framlingham. Collingham. Rayleigh.
		March 6	Harleston.

WE all know that correct Agriculture presents to our view a series of the most beautiful illustrations of natural laws, and an amateur of the art may well be carried away by enthusiasm while observing how the facts which come under his eye in the field tally with his scientific knowledge previously acquired in the closet; and he may well be excused instead of being ridiculed for the losses which this enthusiasm, when unbridled, entails upon him. But we must endeavour always to keep in mind that Agriculture is a business by which men earn a livelihood; that it ought to be considered only in the matter-of-fact light of a means of investing capital and labour; that *that* only is an improvement in it which increases the profits of this investment. Now, the means of thus improving Agriculture are two-fold, viz., those arising from the existence of defects in modes of producing, whether the produce be vegetable or animal; and those dependent on the state of the market for articles of produce; and these last are often made use of, as, for instance, when a farmer resolves, after a consideration of market prices, to change his rotation of crops, substituting one crop for another, or commencing the cultivation of, to him, an entirely new plant. It is to an instance of the latter kind that we intend at present to refer.

Several of our correspondents have asked from us an account of the CULTURE OF FLAX. This plant is cultivated to a considerable extent in this country; to an extent which, owing to the disinterested labours of Mr. Warner, of Trimingham, Norfolk, and to the labours of a Flax Improvement Society at Belfast, is rapidly increasing. It is chiefly confined to the alluvial districts of England and the rich loamy land of North Ireland, these being the descriptions of soils preferred by the plant. To show the rapidity with which the cultivation of this plant is increasing, we may mention that at the third Annual Meeting of the Society referred to above, Mr. S. R. Mulholland said that "the firm with which he was connected had, on an average of previous years, sent no less a sum than 40,000*l.* annually of ready cash out of the country, for the purchase of Flax; but this year they had not expended abroad as many pence." And to show what extent of land in Ireland bore Flax last year, we may mention that it is estimated that 37,817 hogsheads of Flax-seed of 7 bushels each, were sown last spring in that country, and each hogshead containing seed enough for three acres, we find that 112,000 acres was the extent sown. This would probably yield on an average 6 cwt. per acre, or in all 36,468 tons of scutched Flax, which at 45*l.* per ton amounts in value to 1,640,925*l.* These figures are taken from the published report of the Flax Society of Belfast, a pamphlet[a] which besides containing much valuable statistical information on Flax-culture, is full of useful practical details. We find in the Appendix to this pamphlet that 55,113 tons of Flax were imported, chiefly from Russia, in 1842, and notwithstanding the increased produce of the article at home, it thus appears that there is still ample market for the article, and every prospect of its continuance.

[a] Proceedings of the third General Annual Meeting for the promotion and improvement of the growth of Flax in Ireland, &c. Belfast, F. D. Finlay, Calender-st. pp. 74.

The Flax-plant, as we have said, grows best on loamy clays: the soil on our alluvial deposits may be considered as a correct representative of them. It is cultivated in various ways. In many districts it is grown after Wheat; in others, Potatoes and other roots are the preparatory crop; and in Scotland, it is frequently grown after Oats which have been sown on lea. As we may safely follow the example of the Netherland farmers in allowing the plant to seed, for Belgian Flax obtains the highest price in the market, we must consider Flax as a seed-producing crop, and practical men join in calling it a most scourging one; and, therefore, its place in the rotation should be after a green crop—a manure-producing crop. The best crop to precede it is Grass.

The land should be ploughed before winter, so as to let the furrow-slice be well reduced by the frost, and when harrowed down as fine as possible it is ready in the early part of April to receive the seed. The thicker this is sown, the finer will be the fibre of the flax, but the less will be its quantity, as well as that of its seed. About 2½ bushels is generally considered enough; it is sown broadcast, and harrowed in. That which is procured from Holland is considered to be the best, but Mr. Babington informs us that the only seed free from the seeds of a most destructive weed, the Flax Dodder, is obtained from America (see page 89).

Flax must be carefully weeded when young; this, however, ought not to be a work of much labour, as the land ought to be thoroughly clean upon which it has been sown. "The period of pulling the plant is determined by the principal object in cultivating it: when it is wished to procure the fibre, the plant should be pulled somewhat green; when it is wished to procure the seed, either for sowing again or for crushing for oil, the plant must remain till the seeds are ripe. This will be denoted by the hardened state of the seed-vessels, the yellow colour of the stems, and the falling off of the leaves. When Flax of good quality, but not extreme fineness is wanted, the best period of pulling is just when the plant has attained its maturity, with respect to the formation, but not to the full ripening of the seeds. When it is required for the finest fabrics of all, as for cambrics and muslins, it should be pulled when it begins to flower."

As we have already said, it is the interest of the farmer to save the seed of the Flax, and therefore it should not be pulled till the seed-vessels have become brown. It is not necessary *now* to detail the subsequent management of the Flax crop; those who wish further particulars will find them in Professor Low's work on Agriculture, from which the above extract is taken, and in Martin Doyle's "Practical Husbandry."

We are far from recommending that the growth of Flax be inconsiderately commenced on an extensive scale; but it is not necessary to adopt the high figures, such as those of our correspondent Mr. Dickson, which are true only of rare cases—it is not necessary to adopt such figures as true on an average, in order to see that the cultivation of the Flax-plant may be profitably entered upon on suitable soils.

WHEN speaking some time since of the probable—and, indeed, in reference to the few experiments that have hitherto been made, the actual—influence exerted upon the future history of the plant, by the process of steeping the seed in certain solutions, we might have enlarged upon one point which was passed over hurriedly. It was stated that the effect of such a process would probably show itself in the rapid growth of the plant through the period of its germination, and the earlier stages of its growth, during which it is peculiarly liable to injury. It was also intimated that steeping the seeds of plants might have a direct influence upon their growth up to a period considerably beyond that of germination. Now whatever direct influence it may thus possess, it is evident that if it have any influence at all on the condition of the plant during its early stages, it must indirectly exert great influence much beyond those stages. And here we may leave the individual case, and consider for a while the importance of the general principle—

THE IMPORTANCE TO A PLANT OF A VIGOROUS HABIT OF GROWTH WHEN VERY YOUNG.

We do not now allude to plants cultivated merely for their roots and leaves—these differ from those cultivated for their seed in a very important point. Let us take the Wheat-plant and the Turnip respectively as representatives of these two classes. In the latter case, the efforts of the farmer are all bent upon obtaining size of bulb: this is the one point which is the object of cultivation; and, however backward the plant may be at an early stage of growth, genial weather and good cultivation may start it again, and quite remedy previous bad fortune: its size will increase under such influence; its growth is from the beginning to the end a mere process of accumulation—a mere work of addition. In the case of Wheat, however, there are several parts to be looked to. It is the seed which is here important; and the farmer aims not only at obtaining size but number also. This number depends on two circumstances—the tillering of the plant, which increases the number of ears from each root, and the size of these ears—the number of seeds on each. The former of these particulars, equally with the latter, renders it of great importance that plants should be placed in such circumstances when young as will enable them to grow vigorously; but it is to the latter point especially that we wish to direct attention. We have pulled a Wheat-plant early in April, when barely six inches high, and on dissecting it have laid bare the embryo ear, then hardly the tenth of an inch long, and by the help of a microscope we have counted the buds upon it, at this early period—the buds from which the flowers and the seed are to spring. Now this embryo ear in the month of April appeared to possess about the same number of parts, each in an embryo state, as the average of perfect ears; and though we do not know that the ear of Corn is formed in embryo perfect, so far as *the number* of its parts is concerned, from the first, yet it is extremely unlikely that in this case any addition would have been made to the number of those parts, for that was already as great as is usually observed. How important, then, that during the very early period, when this number admits of increase, the young plant should be in a vigorous condition! No future exertions, seconded though they may be by genial weather, will here remedy a fault occasioned by inattention during the first stages of the plant's growth. It is *then*, that the limits are assigned to *number*, and any future vigour on the part of the plant must expend itself in the production of size, and in the full filling up of all the parts which have been formed in an embryo state. This latter point is doubtless of great importance; and the farmer, by all means in his power—the right preparation of the land and due thinness of sowing—must endeavour to push the plant on so as to induce the fertility of all the buds on the ear, which is, be it remembered, of rare occurrence; but let him, by careful attention to these same means, endeavour in the first place to obtain length of ear, such a number of buds on each, as, if all brought to perfection by a good season, may result in a large crop.

ON THE FARMER'S CAPITAL.

WE believe that error is often committed in estimating the capital required on entering a farm; various estimates have been made, but all of them have disappointed the farmer. This remark is suggested by the notice in your *Agricultural Gazette* of the 6th ult., that Professor Low says, "Let no man venture on a farm without having a sufficient capital to work it, which from long experience I compute to be about 6*l.* per acre."

Before we can enter into an estimate of the capital required, we must not only know the kind of farm in question, whether it be a dairy farm, a grazing farm, a stock (hill) farm, or an arable farm; we must also know the state of culture it has been in, and in which it is to be left by the out-going tenant, and the cultivation or tillage and crops the in-coming tenant has to take to and pay for, before we can attempt an estimate with any chance of approaching near to the sum required. Let us, therefore, suppose a case where a lease has just expired, and where a just and rational system of culture has been embodied in the conditions of it, binding the tenant after every seed-producing crop to have a root or dung-producing crop, to be all consumed on the farm; binding him also to apply all the manure to the production of the roots; and to continue this system from the beginning to the end of the lease; but giving him absolute property in all straw and manure of the last crop, for which, as it belongs to the farmer as much as the grain produced or the stock reared that year, he ought when he leaves the farm to get the full value. And, beside this, as half of the culture and the manure put on to produce the root-crop of the last year of his tenancy has not been exhausted, but remains in the soil to produce the seed-producing crop of the in-coming tenant's first year, the out-going tenant ought to have the full value of it.

It is not necessary, at present, to enlarge upon the merits of these conditions in a lease. Believing that they ought to be embodied in the clauses of all leases of arable land, I merely allude to them now as affecting the subject in hand—the capital which the in-coming tenant will require.

I suppose the farm to be one of 300 acres, 240 of which are arable, and the remaining 60 acres in permanent pasture. Of the 240 acres, say 40 acres, or a sixth part, is in Clover; 80 acres, or a third part, in roots or dung-producing crops; and 120 acres, one half of it, in Wheat, Barley, Oats—seed-producing crops. I suppose, further, that the term ends at Michaelmas, with a clause in the lease embodying the conditions already alluded to, binding the landlord or his in-coming tenant either to take to all or to any part of the 80 acres of roots, all or any part of the straw, and all or any part of the Hay (if the Clover be made into Hay) at a valuation, or to allow the whole, or what he does not take, to be disposed of, to be carried off the land; also to pay for one half of the value of the manure applied to the cultivation or tillage of the 80 acres of the root-crop of the last year; and if the Clover has been pastured by sheep being folded thereon, instead of being made into Hay, to allow the value of the manure which the stock has dropped during the time they have been depasturing it.

A farm entered upon under such conditions would be in such a state of culture, that the first crop of the land to the new tenant would be as productive as any of the crops which the last tenant had during the whole of his lease, and the amount paid by the in-coming tenant would be

satisfied to lean on the contemplation of the root and the Corn crop at harvest. And assuming that such cultivation-clauses as were in the last lease are continued in the new one, we proceed with our estimate of the capital required for such a farm: an estimate, viz., of the capital required to cultivate a farm of 300 acres, of which 240 is in arable culture, and 60 in permanent pasture: the arable land to be cultivated so as to have one half of it (viz., 120 acres) in Corn every year, and the other half of it in roots and Clover; 40 acres in Clover, and 80 acres in roots.

Working Cattle.			
To 8 working horses and a saddle-horse			£270 0 0
Implements.			
Plough and cart-harness, 1 saddle, &c.		£6 6 14 0	
8 one-horse carts, at 12*l.*		96 0 0

7. Tillage and stock			745 0 0
8. Gross-rent for one year			637 10 0
			£4068 7 0

According to the above estimate, the farmer requires a capital of about 13*l.* per acre to cultivate arable land, under such conditions of entry as we have before named. Under these conditions the out-going tenant has no interest in running out the land during the last four years of his term; because he gets full payment for all the cultivation he has left in it, and also because he gets the full value of his last year's crop of straw and roots, either from the in-coming tenant or from public sale. The sixth item in the estimate seems large, but we have seen as great a stock of sheep, and of as much value, on many of the best-cultivated farms in Lincolnshire and Norfolk; and we suppose the root-crop, as in these districts, to be consumed by the farmer's own stock. The 7th item is a payment to the out-going tenant, for the good state of cultivation in which he has left the farm, and it is much less than the new tenant would have to sink in order to recover it into that state had he entered upon a farm which had been run out by his predecessor. I have sunk upwards of 800*l.* during the first two years of my tenancy, and got a farm not so large into a tolerable state of cultivation, without getting a single sixpence of return from it till towards the end of my term, during the last four years of which of course I endeavoured to take it all out again, knowing, from the nature of my term, that this was the only way I could ensure myself against loss. The 8th item contains the rent and parochial taxes, all these becoming due and requiring to be paid out of the capital before any of the crop can be brought to market.

According to Professor Low, a farmer's capital is not quite one-half the sum I have estimated it to be in the best-cultivated districts of Lincolnshire. This, however, may, I think, be explained by the mode which the Lothian farmers adopt of consuming their produce, and by their mode of entry and of paying rent. Thus, the 1st, 2d, 3d, 4th, and 5th items of the above estimate I believe give pretty nearly the amount required by the East Lothian farmer; but in the 6th item I think we shall find a very great difference. If it be true that the arable farmers in the Lothians and Roxburghshire sell all their roots, &c., to the hill or stock farmers to be consumed on their own farms by the other's sheep, then nearly the whole of this item of 1,085*l.* will not be required by them as capital; again, the 7th item will also have to be altered, for the term of the out-going tenant is, there, always May-day (although he gives up to the in-coming tenant all the land in course for Wheat at Midsummer, and all the stubble at Michaelmas); and, of course, he consumes all his roots and straw by stock in the coverts, converting it into manure, as this is the only article he is paid for by the in-coming tenant. This item may, therefore, be reduced to the value of 1,500 cubic yards of well-rotted dung, at 4*s.* per cubic yard; so that it will now stand at 300*l.* instead of 745*l.* Again, the 8th item must be struck off altogether, because the rent in the Lothians, as well as over Scotland generally, is made to become due 18 months after the term of entry; so that this 637*l.* 10*s.* is not regarded as any part of the farmer's capital. The gross rent in Scotland is generally paid to the landlord; there are no tithes, nor poor-rates, nor church-rates, and the only parochial rate is the statute-labour (the road-rate in England), which on a farm of this size may amount to about 4*l.* per annum. Thus, then, we have reduced our estimate, under the Lothian system, as follows:—

1. For working cattle	£270 0 0
2. Implements	450 2 0
3. Food for working cattle	266 0 0
4. Seed-Corn, &c. &c.	150 10 0
5. Servants' wages, Harvest work, &c.	439 4 0
6. Cows, pigs, say	100 0 0
7. 1,500 cubic yards of dung, at 4*s.*	300 0 0
8. Rent (statute labour)	4 0 0
	£1968 17 0

Or about 6*l.* 10*s.* per acre—nearly Prof. Low's estimate.

It only remains to add to these observations a few remarks on items 1, 2, and 5. The capital estimated as necessary under these heads is supposed to be spent in the purchase of everything that is best of its kind, whether it be strong and active horses, efficient and newly-made implements, or intelligent labour; for it is believed that capital so spent will yield a larger annual interest than a less amount spent in the purchase of third-rate horses, second-hand implements, or spiritless labour. Possibly the first two of these items might be reduced one-half by the purchase of horses and tools "good enough for a tenant-farmer," as the common but most erroneous saying has it, and I doubt not but that labour may be had in certain districts one-third cheaper than what I have estimated it at; and looking at this, many will say that the annual return from the employment of such, being nearly equal to that from the 1st class description of stock, which I suppose the farmer to purchase, and the expense of obtaining such being barely more than one-half of that which I suppose the farmer to incur; the interest yielded by the former must be nearly double that yielded by the latter; but it must be remembered that in both cases, in order to calculate the interest yielded by capital thus employed, we must subtract from its gross annual amount, so much as is necessary to keep the stock good; so much in fact, as, added to its value at any time, will enable the purchase of other stock of equal value with that which was purchased to begin with. It is the net annual return thus obtained which is the true interest of our capital. Now the rapidity with which second-hand articles wear out, the amount of disease and death amongst third-rate, *i. e.*, half worn-out horses, and the loss from idleness by the use of half-paid labour, are all so much greater, and in fact the money value of these losses is so much more than double that of the losses under these several heads, under the system I have recommended, and on which I have calculated, that when their respective amounts come to be subtracted from the gross annual returns of capital employed, with which they are respectively connected, even though these returns should be of equal value, which is not reasonably to be expected, I venture to say that the one will thus be so much more reduced than the other, that the annual interest or per-centage, derived from the less amount of capital invested in inferior stock, will be much less than that from the greater amount invested, as I have supposed it to be, in first-rate stock.

The subject of the "capital required by the farmer" is one necessarily of first importance to Agriculturists, and none could better occupy the thoughts or employ the pens of the readers of the *Agricultural Gazette*. I hope that a discussion on this subject conducted here may be useful in bringing out the truth of the matter.—*John Morton, Chesterhill, Stroud.*

The guano consisted of four different samples, distinguished by the marks above given. When applied it was mixed with sifted earth, and then sown in the bottom of the trenches, and well watered. The salts were applied after the plants appeared above-ground.

This result was obtained from the Bread-fruit Potato, planted in the London clay, well drained, and largely mixed with old plaster. The piece of ground was here and there shadowed by trees, so that the total produce was thereby diminished. It had borne a much heavier Potato crop the previous year, as is reported at p. 551 of the *Chronicle* for 1842.

It is sufficiently clear that there is much difference in the quality of guano, all these samples having been furnished by one of the most extensive importers, for the purpose of experiment.—*John Lindley.*

REPORT OF DR. VON MARTIUS ON GUANO.

(*Continued from page* 182.)

The proportion of soluble salts in the guano appears, from the two most recent analyses, to be much greater than in dove-cote manure. According to Klaproth they are only 16.5 per cent.; but according to Völkel they are 39.22 per cent.; and according to Vertels, 44.858. So that if the manuring power of guano be allowed to be in proportion to its soluble ingredients, it will be, in comparison to dove-cote manure, as 39 to 16 according to Völkel, and 44 to 16 according to Vertels. But we may very correctly estimate the manuring power of guano at a higher rate than its solubility, as the nature and combination of its salts are of importance. So that it would not be an over estimate to say, that the manuring power of guano is four times stronger than that of dove-cote manure.

These speculations are confirmed by practice. In Arequiqua, on the coast of Peru, if a field of Potatoes or Maize yielded an eighteen-fold produce with ordinary manure, it yielded, when guano was used, forty-five-fold of Potatoes, and thirty-five-fold of Maize. On the growth of Grass, according to experiments made at Hamburgh, it has an extraordinarily favourable influence. An experiment was made at Flotbeck, near Hamburgh, on a piece of grass, which bore a second cutting five days after the first, whilst double the length of time was required on the ordinary method. For the speedy growth of grass on dry soils, and for the improvement of poor meadows, which are common near Hamburgh, it has been strongly recommended in the Transactions of the Prussian Horticultural Society.

In Peru, three fanegas of guano, or about 7¼ Spanish pounds, are laid upon a tapo of land, which is about a three-

rienced. In England, two cwt. (centner) has been added to an acre for Wheat, and four cwt. for Potatoes and Turnips. In England, on account of the facility and cheapness of transport, the guano seems to promise most. In Peru, a fanega or 256 French pounds, cost between three and five florins (from 5s. to 8s.). In Hamburgh it is sold at from 3½ to 5 six-dollars (from 9s. to 14s.) per cwt., according to the quantity bought. In Germany, the use of guano can only be recommended in Bavaria, where it is found to be cheaper than bone-dust or *Poudrette*. It is, however, very desirable that some of the rich possessors of land should try some experiments on the subject.

Guano recommends itself on account of its great concentration, and the facility with which it may be employed where heavier manures cannot be carried. It is very probable that many of the steep, stony, mountainous districts which possess at present little soil, but by further breaking down, promise a rich vegetation as soon as they shall be brought into cultivation,—such for instance as the steep ridges of hills in the Rhenish vine regions, would quickly repay the expense of manuring them with guano. But it must not be concealed that such culture in the first instance would require a considerable outlay of capital.

With respect to the peculiar nature of guano, from containing many volatile ingredients, which are lost by immediate contact with the atmosphere, it should be remembered, 1st, that it proves less beneficial for manuring in winter than in spring; and 2d, that it is used cheapest where it can be dissolved, and consequently where manure cannot be carried, yet where a spring of water exists, by which the guano may be dissolved, it may be used successfully.

In America, the farmer often takes a small quantity of powdered guano, about as much as he can hold in his fingers, and places it in a shallow hole at the root of any plant to be manured, and then pours over it a small quantity of water. Guano cannot be recommended in those districts of Germany where the expense of carriage would counterbalance its advantages, or where water cannot be easily obtained. In the cultivation of gardens it promises much, as well as for increasing the growth of Grass on pleasure-grounds.—*Munich, Feb.* 13, 1843.

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. VIII.

(Continued from page 123.)

Of the Inorganic Elements in the Composition of Plants.*

Lime.—Composed of calcium and oxygen, one equivalent of each—exists in variable proportions in almost all plants, and, consequently, must form part of the soil in which they grow. It is essential for the formation of bone in animals, hence the necessity for its existence in plants. United with carbonic acid, it is known to the farmer as chalk, marl, &c., with sulphuric acid as gypsum, and with phosphoric acid as phosphate of lime.

Phosphorus united with oxygen forms phosphoric acid, which again uniting with lime, forms the phosphate of lime above alluded to, and this is contained in considerable quantity in the husk of grain. Phosphate of lime is the form in which the earth of bones is deposited. Phosphorus is also essential to the formation of brain and nervous matter. Its importance, therefore, as an ingredient of the soil is evident, and the more so as it is the inorganic ingredient most deficient in all soils. Bran, which contains the phosphate of lime, is therefore a good manure when added to other ingredients. Crushed bones, of course, contain it in abundance, united with the azotised principle gelatine. In some remarks which have been made upon the experiments of His Grace the Duke of Richmond, the fact of the sulphuric acid which was added preventing the escape of ammonia from the decomposition of gelatine has been lost sight of. To be an efficient manure, phosphate of lime must be added to other species of food; thus in guano it is united with sulphate of ammonia; and in the experiments of Mr. Lawes, of St. Alban's, the union of phosphates of lime and ammonia succeeded best.†

Silicon united with oxygen, as silicic acid, and, again, with potash as silicate of potash, is essential to the stiffness of stalk in the Cerealia. Wheat grows best on light lands, when they contain much silex in the form of fine sand.

Potash.—This, which is a compound of potassium and oxygen, is also an essential ingredient in the soil for agricultural purposes. If it is deficient, the stalks of the Corn do not become stiff, and are subject to mildew and other diseases. A gentleman in this neighbourhood, Mr. Boby, informed me that his father used to burn the straw from his farm for the purpose of procuring the potash. The consequence was, their crops became subject to mildew. The potash manufactory was given up, and the mildew ceased. Either potash or soda are necessary in the soil of all pastures or meadows, for without the alkaline base the cows would produce no milk.

Sulphur is found in most soils, and also as a constituent of plants. Its use in the vital economy is not exactly known, but that it is important is proved by its presence in the egg. With the exception of lime, it is the most constant inorganic constituent of animal structure.

Iron has a very important function to fulfil in the animal body. It exists as an oxide in the blood of all vertebrate animals, and serves the purpose of a "carrier of oxygen" from the atmosphere, through the lungs to all parts of the body. It is therefore an essential ingredient in the plants upon which animals feed.

* This part of the subject is so well handled in the papers now publishing in The Gazette by Prof. Sprengel, that I need do little more than allude to each.

† Vide *Agricultural Gazette*, 13th January.

The constituents of plants forming food for animals classed thus:—

NON-AZOTISED.

Sugar, Starch, Gum, Oil, Fat, Wax	For supporting respiration and animal heat, and for the formation of fat.

AZOTISED.

Albumen, Fibrine, Casein	Restoration of waste, formation of muscle, and all other organic tissue of the animal body.

As existing in the gluten of Wheat, &c., the legumen of Peas, Beans, &c.

Inorganic Elements.

Lime	— for the formation of earth of bone.
Phosphorus	for the formation of brain, nervous matter, and earth of bone.
Sulphur	— not known.
Potash or Soda.	for the formation of bile, milk, &c.
Iron	— as a carrier of oxygen.

Silica and Alumina are not used in the vital economy of animals.

The chemical composition of crops will be best considered in the next section, where I propose to treat at some length the subject of the practical application of manures.—*C. R. Bree, Stowmarket.*

(To be continued.)

ON MINERAL AND INORGANIC MANURES. No. IX.

By Professor Charles Sprengel.

Another very important substance contained in marl is the phosphate of lime. It neither occasions nor undergoes any decomposition in the soil, yet it improves the plants more than any other of the component parts of marl—it supplies them with phosphorus, so indispensable to vegetation. Phosphate of lime, as we know already, is not soluble in pure water, yet it dissolves in such as is impregnated with either humic or carbonic acid; from which it may be seen that it is important, even in this respect, that a soil to be manured with marl should contain humic acid. The quantity of phosphate of lime which the soil may obtain from marl is often greater than may be believed, because if the marl contain only ½ per cent. of the above phosphate, 20,000 lbs. of marl used on one acre will bring 100 lbs. on this area, which is enough for more than 100 crops; and there are marls which contain about 2 to 3 per cent. of phosphate of lime.

If marl contains gypsum, which is often the case, it is one of the most valuable of its ingredients, as it is well known how astonishingly this mineral substance promotes the growth of plants. Gypsum passes into plants without being decomposed, and is soluble in 450 parts of water. If any sort of marl were merely to contain ½ per cent. of gypsum, 20,000 lbs. of marl would bring 100 lbs. into the soil, and this would have a great effect on the first crops; and there are sorts of marl which contain 2 to 3 per cent. of gypsum.

Marl also generally contains common salt, which passes without decomposition into plants and nourishes them. By this substance, however, marl acts only for a short time, because common salt is easily soluble in water, and is only contained in the marl in very small quantities. It does not effect any decomposition in the soil.

A substance found in many sorts of marl, especially those of alluvial lands, is silicate of potash. It is not soluble in water, and therefore cannot serve as food for plants until it is decomposed by the humic and carbonic acids of the soil, and converted into humate and carbonate of potash, which are easily soluble in water. Some marls contain one per cent. of potash combined with silica; if, therefore, 20,000 lbs. of marl are conveyed on one acre, the soil will obtain thereby 200 lbs. of potash, on which account the effect of the silicate of potash, which is difficult of decomposition, will last for many years. Another ingredient of several marls of the alluvial lands, is silicate of soda. I have found in several of them so much as 1½ per cent., and as (like the silicate of potash) it is successively decomposed by the humic and carbonic acids, and changed into carbonate and humate of soda, such marl will supply the crops for many years with soda.

At times marl contains also an ingredient which will chiefly improve the growth of cerealia, and this is saltpetre. It will, however, act but very transiently, as its amount is mostly very small, and as it is too easily soluble in water for the furrow slice to retain it for any length of time; it neither induces nor undergoes decomposition, but acts directly on the plants.

(To be continued.)

MANX AGRICULTURE.—No. IV.

(Concluded from page 123.)

Before concluding this sketch of Manx Agriculture, it devolves upon the writer, as an impartial historian, to point out any circumstances of a counteracting nature, the knowledge of which may be essential to the personal comfort or the worldly success of an intending emigrant. The chief difficulty which the "stranger" (as every settler in this colony is called) has to encounter, arises not from an ungrateful soil, or a capricious climate, but from the state of existing Manx laws and institutions. The domestic government of the colony is vested in a Governor with his Council, and in the House of Keys. The latter was in better times elected by the people, but now consists of 24 self-elected and irresponsible men.

The island is happily free from the jarring contests of politics, and in a small agricultural community this must be considered as no social evil. Questions of church-rates, *pro* or *con*—the uneasy pokes of an income-tax, or of Queen's taxes, poor-rates, heavy turnpike tolls—vex not the spirit of the Manx farmer; for of all these he is happily ignorant. Little more is required to promote peace and harmony, than the faithful discharge by our Legislature and rulers of their responsible duties.

The present law of arrest is one of the greatest barriers to a stranger's comfort, and, as a consequence, to the island's prosperity. It will surprise the English reader to be informed that it is in the power of any Manxman to arrest a resident stranger (should he even be the lessee of the freeholder of 100 acres) for 5*s.*, nay for 5*d.*, if he (the native) will venture to make oath that he has heard and believes that the stranger is about to leave the island; or he can arrest for any sum above 40*s.* upon a mere loose affidavit that the debtor is not a native of the island.

The frequent facilities which fraudulent debtors possess for escaping to the neighbouring kingdoms, render it quite necessary that some check should be provided for the protection of the creditor; but the stranger has surely a right to expect that such protection should be reciprocal, and that he too, in case of need, shall have an equal right to arrest his Manx debtor. As the law now stands, he has no such privilege.

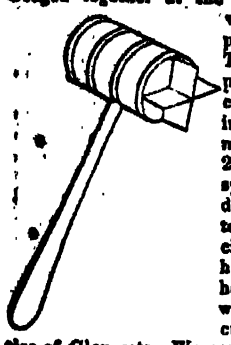
If he can positively swear that a native, in his debt, is about to leave the island (a subject upon which he may expect no previous information), he can arrest him; but, as before stated, *the stranger* is liable to summary arrest upon the loose oath of his creditor that he "is not a native of the island." Englishmen would almost stand aghast at the tyrannical and galling manner in which the law may be, and often is carried into effect.

The debt may be altogether a fallacious one, or it may arise upon a disputed account, or, what is worse, may be a mere speculative action for damages, as for a libel, an assault, &c., which when brought before a Jury falls to the ground, or perhaps is never brought before a Jury, because the stranger would oftentimes prefer to submit to extortion or to a robbery rather than be torn from his family and his property: the former to be afflicted, and the latter to be distributed during his incarceration. But setting aside commercial engagements (which are allowed to require some extra protection), it is an unpleasant part of the writer's duty to state that the tenant-farmer is placed in a still less enviable position. The laws endow the landlord with the power of arresting for rent before it is due: a tenant may enter upon a farm at Lady Day, or at any other period; he may stock, manure, clean, and crop it, and yet the landlord has the power to arrest the man and imprison him until he finds security for the current year's rent; and, although he may have in hand to-day his landlord's receipt for rent due yesterday, he may to-day be called on to find security for the next year's payment. It is an ungrateful office to announce that such senseless laws should exist in an island claiming to be civilised, and situate within a day's journey of the metropolis of the world; but it would ill accord with the writer's duty to leave these facts unnoticed.

It is but just, in conclusion, to state that an active, industrious farmer, with adequate capital and of conciliating disposition, will find little practical obstruction from these causes. Let the Legislature of the island, who may literally be said to hold the "keys" of its prosperity, only unlock its resources by the timely improvement of its institutions; let it hold the scales of justice fairly balanced between the native and the stranger, and Mona, if not destined to become, in the language of the poet—

"The first flower of the earth,
The first gem of the sea,"

may nevertheless remain the abode of industry, plenty, and harmony; and should be content if, in the peaceful contests of civilisation, commerce, and Agriculture, she can give full effect to her ancient motto of war—



"Quocunque jeceris stabit."

—*Cultor.*

Home Correspondence.

On Gorse.—My attention has been drawn to an article on "Gorse, as a Winter Food for Horses," in your Paper of the 3d ult., and as I can speak from experience, I herewith send you a few remarks on the culture of the Furze—its preparation for food, and its results, as a winter food for all cattle, but more especially for milch cows. Furze will grow well on any soil which is of a dry, gravelly, sandy, or loamy nature. The seed should be sown about the beginning of April, in drills one foot apart, after the land has been made as clean as possible. As soon as the plant appears, the ground should be hoed. In the February following, you may brush off with a scythe what little crop there is, for litter. Continue hoeing till the following November, when you may begin to cut for food; the crop will be comparatively small, but much better the following year. No manure whatever is required in any stage. The period for commencing cutting must be regulated by the season, from the latter end of October or beginning of November, till the middle or end of March, when the sap begins to rise, and the cattle do not relish the food so well. A labourer cuts and carts home sufficient for a day's consumption with a short strong scythe, such as is used for mowing rough grass, or for stubble cutting. On Saturday enough must be cut and prepared for the following day, and to prevent fermentation it must be spread thinly on a barn floor, or other boarded place; and perhaps some chaff mixed with it would assist in preventing fermentation. The least expensive method of preparing the Furze for food, is on a floor of Oak or Ash stubs, raised about 16 or 18 inches above the level on which the labourer stands to chop it. The floor should be about seven feet long and three wide, quite level, and the stubs or blocks of wood both firmly and nicely fitted together; and if placed in the corner of a barn or lodge, additional firmness would be secured by making the building form the back and one side. Round the outsides, in order to prevent the Furze tumbling out, must be placed a strong skirting

board, about seven inches higher than the floor. A certain quantity of Furze, as brought from the field, is trodden down on the floor. The instrument used for chopping is a wooden-headed iron-bound cleaver (such as is used for driving wedges), into the head of which are driven two knives, let into each other at right angles, and wedged together at the bottom. The subjoined is a wood-cut of this instrument, placed so as to show its knives.

The Furze is chopped till the prickle is so subdued that it can be masticated without inconvenience. An able-bodied man will prepare from 20 to 25 bushels per day. If this system (which we will call for distinction, the chopping system), does not prepare a sufficient quantity of Furze for your horses and cows, resort may be had to the grinding system, which is done by the stone cider-mill, as used in the counties of Gloucester, Worcester, and Hereford; it is better that the trough and wheel be shod with iron. There is only one objection to the iron, which is, that sheep will eat, and like other animals no doubt, eventually like the Furze, but they dislike (as I believe it is generally allowed) any food bruised with iron. Preparatory to the grinding, the Furze goes through Passmore's chaff-cutter, which may be worked by hand or by a fly-wheel attached to the axis of the cider-mill. The Furze, cut to the length of an inch, is then ground in the mill till the prickle is completely destroyed. The expense of this apparatus cannot well be reckoned under £*, while that for "chopping" may be erected for about 60*s*. I have seen other plans for bruising Furze. The specimens exhibited at the Royal Agricultural Society's shows were none of them I believe considered of sufficient merit or utility to entitle them to the premiums. Much, however, as it is to be desired that some plan might be invented, whereby small occupiers and poor persons living on commons or wastes, may convert the wild growing Furze into food for their cows during the winter, I am inclined to think, from what I have seen of the working of the various implements, that those only which involve the principle of a heavy roller on a plain hard surface, can do the work speedily and effectually. As to the quantity of food to be given to each animal, this must depend on their size and constitution, and it will require the constant watching and judgment of the feeder. For some cows, three bushels will be sufficient; others will consume four bushels per day. A small quantity of salt should be added to every feed, and as Furze is of a binding nature, a single root of Mangold Wurtzel should be given each day, either before or after one of the feeds, when necessary. A bait of Hay, from three to five pounds per day, may also be given to each cow or other animal, but it is not in all cases necessary, as from the time six Alderneys were put into the yard, up to the 6th of April, 1840, they did not have a single blade of Hay, and instead of Mangold Wurtzel, about a month before and after calving, they had a few white round or Swede Turnips. The quantity of salt, the size of the root of Mangold Wurtzel, and the Hay (if given at all), will be regulated by the feeder's observation of the animal's requirement. One acre of tolerably strong Furze will keep two cows about 20 weeks. The Furze must be of one year's growth only, and cut close to the ground, and if the whole of the field is not used, it must be mown off about March. At this time it is necessary that the person usually cutting the Furze should examine the whole field, and cut off close to the ground any stubs that may have been left, otherwise they become next year too strong for the scythe. On food prepared as above, the cows do well and are healthy, and the quality of the milk and butter is very much improved both in sweetness and richness. I am inclined to think that your correspondent has been misinformed about the large dairy now at Birmingham of two hundred cows kept on Furze during the winter. It may be the case; but I think it more probable that his informant has heard of an establishment that has been for many years kept by a gentleman near Worcester, to whom your readers are indebted for the subjoined figures; being a comparative estimate of the expense of feeding 24 cows per week on *Furze* and *Hay*, computed with the greatest accuracy.

Furze principally.				*Hay entirely.*			
160 bushels of Furze, cost 2*d.* per bushel grinding	£1	13	0	2 ton 16 cwt. at 3*l.* per ton	£11	4	0
Cost of cutting and carting home	0	16	0	Man's time	0	12	0
24 cwt. of Hay, at 4*l.* per ton	4	16	0		11	16	0
16 cwt. of Mangold Wurtzel	0	10	0	Expense of Furze	8	9	0
Man's time	0	12	0				
	£8	9	0	Difference in favour of Furze	£3	7	0

I have endeavoured to lay before you these facts as clearly as possible, and must leave your readers to judge of the value of the Furze from these statements, which are grounded on the experience of several years.—*Vigora.*

Lucerne.—I send you the following extract from Professor Low's work on Agriculture, on the cultivation of this plant.—"The best period of sowing Lucerne is at or before the middle of April. When sown broadcast the quantity of seed per acre may be 16 or 18lbs.; and when sown in rows 10lbs. The soil should be well prepared by deep ploughing, and a previous summer fallow or fallow-crop, such as potatoes, turnips, &c. When drilled, the rows need not be more than 18 inches apart, which will give room for tilling the intervals by the horse and hand-hoe. After the seeds are sown, care must be taken to keep down, by means of the hoe, all weeds that spring up amongst the plants, and in the rows. In the month of August of the first year, when in flower, the crop may be mown, and after this cutting, the shoots may be kept down by a slight pasturing with sheep, but not while the soil is wet, nor continued till a late period. Early in the following spring the ground is to be horse or hand-hoed, so that all weeds may be kept down, and the earth stirred about the roots of the plants. In the month of May the crop will be ready for the first cutting. After being cut, it is to be horse-hoed in the intervals. It will now grow very rapidly, and when ready for cutting is to be cut again, and after each cutting hand-hoed; in this manner it may be mown four or five times in the season; it does not, however, arrive at maturity till the third year; it requires to be manured at intervals, as every fourth or fifth year; the manure may be farm-yard dung, spread upon the surface after the last cutting in autumn, or early in spring."—*M. S.*

Seaweed as Manure.—The Isle of Thanet is celebrated for its fertility. It sends a great quantity of the very best Wheat to the London market, and produces, in addition to the more common grain, large quantities of Carraway, Coriander, Spinach, Radish, Canary, and other seeds. In many parts of the island the soil is naturally very shallow and poor, but these are rendered extremely productive in consequence of the extensive use of Seaweed as manure. This appears to be a comparatively modern usage. Lewis, in his History of Thanet, written in 1723, in a short account which he gives of the system of agriculture followed in this island says, "Within these few years past the inhabitants of the North and East side of the island next the sea, have made great use of the Alga or Sea Woor, which is often cast up by the sea in great quantities under the cliffs. This the farmers carry on their maxhills, where they mix it with their other dung, which it helps to rot. In this mixture they observe no proportion, but endeavour to have one layer of dung and another of Sea Woor, which they turn once or twice in the summer in order perfectly to mix and rot it. But it is observed that the Sea Woor is not so kind for the land lying near the chalk as for the colder land; and that where the land is very cold the best way is to carry out the dung rough, without laying it into a maxhill at all. The stench of this weed when first laid on the maxhills is very nauseous, but as it is in the open fields, is the more tolerable." The Seaweed is now one of the mainstays on which the farmer who is near enough to the coast depends. Deep cuttings have been made through the chalk cliffs for the convenience of carting up the Seaweed; and as this is very hard work for the horses, the team is in general peculiarly good. They do not wait for any decomposition, but collect it as soon as it has been thrown up by the storms. The common custom is to lay alternate layers of Seaweed and sand, which are turned frequently till the whole is decomposed. I have not heard that the manure is not found as good for the shallow land; indeed, I believe the present fertility of a considerable portion of the land depends mainly on the use of this manure. Neither, again, have I heard that after a series of years the land becomes deteriorated by the presence of magnesian salts. Seaweed is, I believe, sometimes used on the coast of Scotland in its rough state as manure, without any previous decomposition, and is considered very good for Potatoes. I don't know whether its use is at all general. The Potatoes in the isle of Thanet, it may be remarked, are peculiarly good, which may possibly arise from the use of this manure.—*M. J. Berkeley.*

Rats.—Seeing that you recommend "Nemo" to smear the holes and passages frequented by Rats with arsenical ointment, I beg to state, that as accidents frequently happen from the use of poison, perhaps some other method might be acceptable. Slice a number of corks as thin as sixpences, and then roast or stew them in grease, and lay them in the way of the rats; these will prove a delicacy, and will be speedily devoured; the rats that partake of them will die of indigestion. Another method is to cut a piece of sponge into small pieces, and fried and dipped in honey; these are placed along with shallow pans of water in the neighbourhood of their holes. By eating the sponge, and then satisfying the thirst which it produces, their stomachs become so distended, that it generally proves a fatal repast.—*Herbert, Sussex.*

Waste Lands, &c.—I quite agree with "H." in thinking that "A National Agricultural Society" should be formed to bring into cultivation the waste lands of the British islands, and to inclose and reclaim from the sea and at the mouths of large rivers, the vast tracts of land which now are not only lying useless, but are dangerous to navigation. When so many hands are now unemployed, and when so much capital is lying useless, no time could be fitter than the present for the formation of such a Society, and I hope it will be taken up in earnest.—*P.*

Manure Dropped in the Field.—By neglect of the simple means I pointed out in No. 4, page 59, *Agricultural Gazette*, the greater part of the manure made in the fields is lost, the common practice being, to allow it to remain until the spring, when it is knocked and spread about. But the misfortune is, that by that time it has become like so many masses of dried turf. It is in reality then deprived of all its fertilising qualities by atmospheric influences, whereas, were it managed in the way I have described, I am quite sure that the results would be most beneficial. I would suggest that profitable employment would thus be afforded for aged persons, who are incapable of more laborious work, and for women. It would be much better and more economical paying for this labour, than laying out money in foreign, or any other manure; and the poor and the infirm would be happier and better satisfied thus engaged, than if imprisoned in a workhouse. If those who read these observations would only just try the plan recommended, they will soon find how easy it is to improve their land without being at any material expense, for the means are always at hand, and only require application. There is another subject which I beg to bring under the notice of your readers. In almost all parks, woods, and plantations, that have come under my observation, I have remarked that the annual waste of the leaves of trees is very considerable; I mean, these are suffered to be dispersed, and have their virtues, as a manure, nearly dissipated by the effects of drying winds. They are sometimes collected by the gardener, who is the only individual who appreciates their value as an ingredient for the composts he requires. If, instead of wasting them, gentlemen would allow the poor, when unemployed, to collect in the woods or fields, the leaves, weeds, and moss, and then purchase it from them at a reasonable rate, what a valuable supply of litter it would bring to their piggeries and sheepcotes. When spread in the yard, and mixed with the dung, it would add greatly to the quantity and quality of the manure, especially if collected soon after the fall of the leaf, before its fertilising properties were diminished. I am inclined to think that manure thus made would be much better than if made from straw alone. Leaves mixed with dung make excellent manure for Potatoes on strong land. They might be employed in sheep-cotes during the lambing season, as litter for the ewes. After being in this way enriched by the dung of the sheep, if mixed with earth and well decomposed, it will form a most valuable and cheap compost; and if simple vegetable leaf-mould is of such vast importance to the Horticulturist, what would it not be in this enriched state to the Agriculturist, for his Grass, grain, or root-crops? Cottagers, also, are often at a loss for litter for their pigs, and farmers do not like to diminish their own manure by giving or selling their straw; but leaves would answer the purpose perfectly, if gentlemen would permit them to be collected from their woods for the purpose. Those who approve of these suggestions will, I trust, point out to the cottagers such an easy way of procuring good litter, giving them permission, at the same time, with certain necessary precautions, to gather as many as they want. The fertility of their gardens will then be increased, and feelings of good-will towards their employers will be excited. —*W. Billington, Underhill.*

Manure dropped in the Fields.—The plan laid down by Mr. Billington is a great improvement upon the present practice of totally neglecting the manure dropped from cattle in the fields. Through him it is that you have the excellent communication of "R. F. S.," whose practice deserves the particular notice of all graziers. By collecting all the manure and placing it in different situations in each field, say one heap in each corner, an opportunity is afforded for making a valuable compost each year. And these fertilising means will be derived from sources which have, as Mr. Billington justly says, been "hitherto almost wholly neglected."—*J. West.*

Lime.—There are few counties in England where lime is more universally used as a manure than in Devonshire. The farmers apply it both to the Wheat and Turnip crops, and many fields I was assured had never received any dung or other fertilising substance during the memory of man. At Castle Martin, in the north of Devonshire, the limestone rock abounds, and is burnt for agricultural purposes; but limestone from South Wales also is brought by vessels to be burnt there, and is preferred by the farmers although selling at a higher price. I collected some samples of both, which yield the following analyses. It appears from these analyses that the value of limestones for agricultural purposes depends in a great degree upon the quantity of carbonate of lime contained in them.

ANALYSES OF LIMESTONES.

	South Wales Stone 2 grammes. Contained per cent.		Devonshire Stone. 1.653 grammes. Contained per cent.
	1st analysis.	2d analysis.	
Silicious matter	0.55	0.55	9.228
Alumina	0.15	0.15	1.573
Carbonate of lime	98.25	98.95	87.258
Magnesia	trace		trace
Carbonaceous matter and loss	1.05	00.35	1.941
	100.00	100.00	100.000

—*J. B. Lawes.*

"*Ought Potatoes to be cut or planted whole?*"—I am in the habit of planting five or six acres of Potatoes yearly, and for the last two years I have planted the greater part with whole Potatoes, and find they produce as good crops as with cut sets, with this great advantage, I have scarcely a Potatoe misses growing, whereas in cut sets I have often had a great loss from dry rot. When taking up the general crop, I pick out my seed Potatoes of a uniform size, each weighing about 1½ oz. I plant them in rows two feet apart, and one foot in the row, and have had exceedingly good crops.—*A. C. Hornecastle.*

Seed Wheat.—I last year made the following experiment, the repetition of which I think may prove interesting and valuable to Agriculturists; and, as I have not leisure nor convenience to pursue the subject myself, perhaps some of your readers may be inclined to do so. I took 12 ears of Wheat; from each of the ears I took the top corn, and sowed them in one flower-pot. I then from

* It is impossible to state any definite sum, as the carriage of the stones composing the mill will vary so much, with regard to distance, land or water carriage. The stones themselves at the pit are not so very expensive.

each of the ears took the corns next to the top, and sowed them in another pot, and so on till I had 12 pots, each containing the corns from corresponding parts of the 12 ears. My object was to see whether or not the corns from all parts of the ear were alike valuable for seed, and if not, what corns were the most valuable. As far as my experiment went, the corns taken from the middle of the ear were decidedly the best.—*D. C.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A Weekly Council was held at the Society's house, on Wednesday last, the 28th. Present: W. Miles, Esq., M.P., in the chair, T. Alcock, Esq., T. Raymond Barker, Esq., Rev. T. C. Browne, F. Burke, Esq., Col. Challoner, F. Clifford Cherry, Esq., H. Colman, Esq., A. E. Fuller, Esq., M.P., H. Gibbs, Esq., B. Gibbs, Esq., W. H. Hurst, Esq., P. Pusey, Esq., M.P., Professor Sewell, and T. Villiers Shelley, Esq. The following new members were elected:—

Stretton, William R., Dany Park, Crickhowell, Brecknockshire.
Whitby, M. P., Newlands, Lymington, Hampshire.
Marsh, John, Lydgate Hall, near Sheffield.
Gillespie, Robert, 39, York Place, Portman-square.

The names of 19 candidates for election at the next meeting were then read.

Cottage Tracts.—The Secretary reported the distribution of 15,000 copies during the past two years, of the articles on Cottage Gardening, by Mr. Main; and on Cottage Economy and Cookery, by Mr. Burke, reprinted from the Journal in the form of distinct Tracts, and sold to members at the prime cost of one penny each. The Council ordered that the question of a further reprint of 6000 impressions of these Tracts should be referred to the monthly meeting on the 6th of March.

Drainage.—Mr. J. Clarke, of Long Sutton, Lincolnshire, informed the Council that little or nothing having been yet done to improve the drainage of the low-land district, near Wisbeach, in which he resided, it had been his wish to draw public attention to the subject, and he had accordingly drawn up a work, of which he then presented a copy to the Council, on "Thorough Draining in Principle and Practice," with its advantages and simplicity as applied to a dead level, addressed to the owners and occupiers of the soil in the parts of Holland, in the county of Lincoln, and the great level of the Fens, for which the Council ordered their best thanks to be given to Mr. Clarke. Colonel Challoner gave notice that he should on a future occasion propose that the Society should offer a prize for a practical Essay on the best mode of draining sandy land.

Southampton Meeting.—Mr. Shelley, as one of the stewards appointed for the Southampton Meeting, informed the Council, that agreeably with the directions of the General Southampton Committee he had, in company with the Messrs. Gibbs, visited Southampton on the previous day, for the special purpose of making the requisite arrangements for the ensuing Show of the Society in that district, and now presented to the Council the joint report of himself and those gentlemen on the results of their personal visit and inspection of the localities proposed for the adoption of the Society, and the conditions under which they were offered. Mr. Shelley having read the report, and detailed to the Council the ruinous propositions made to them by the authorities of Southampton, and the great difficulties which presented themselves at every stage of the proceedings, concluded by giving notice that he should move at the next monthly Council to be held on the 6th of March—

That, owing to the difficulties alluded to in the Report of the Stewards, the propriety of holding the Annual Meeting of 1844 at Southampton be reconsidered.

Mr. Gibbs also gave notice that he should, at the same time, move the following resolutions:—

1st. That the bye-law regulating the selection of the place of holding the Annual Country Meeting be suspended.

2dly, That in future the place of holding the Annual Country Meeting shall not be decided upon, until three Members of the Society, who have acted as Director or Stewards of the Yard, shall have visited and inspected the several towns and their localities, and have reported upon their respective fitness for the purposes of the Society.

The Southampton Committee immediately held a meeting for the purpose of enabling them, by reference to all the documents in possession of the Society which had been received from the Mayor or other authorities in reference to the Meeting of 1844 at Southampton, to lay before the Council the specific declarations which had induced them to prefer the site of Southampton to that of other places which had been offered to the Society for the purpose of holding that Meeting.

Sir John William Lubbock, Bart., communicated suggestions on the subject of farm-buildings and cottages, which were received with thanks, and referred to the Journal Committee; Mr. Cottam applied for leave to exhibit at his lecture on the Mechanics of Agriculture, at the Royal Institution, on the 8th of March, the Society's model of Lord Ducie's Uley cultivator; and leave was granted accordingly. Mr. Rickards presented to the Society a copy of his "System of Agricultural Accounts;" Col. Greenwood a copy of his "Tree-lifter;" and Professor Royle, on the part of the East India Company, a collection of Pine-seeds, received from the Company's botanic garden in the north-west of India: for which the best thanks of the Council were ordered.

The Council then adjourned to Wednesday next, the 6th of March.

FARMERS' CLUBS.

Wrentham.—At a recent meeting of this Club, a discussion took place on the most effective means of hindering the destruction of the Wheat-plant by slugs and wire-worms. With regard to the former of these, several remedial measures were stated to have been pursued; the application of soot, lime, or common salt, in small proportions, had each been attended with some degree of success. It would appear necessary that the application of any of these substances be in the night only; for, unless the slugs are exposed at the time of sowing, such measures would prove ineffectual. Another plan pursued was that of slicing Turnips about the land; but the most beneficial effects were experienced by strewing the land with the tops of Turnips only, and in sufficient quantities to afford ample food for these mollusca. Where this latter system has been adopted, the result has generally been, that the plant of Wheat has been preserved, while the leaves of the tops have been almost entirely consumed. The injuries done by slugs are principally confined to an early stage of the Wheat-crop, while the ravages of the wireworm frequently extend over a length of time, and affect the crop at different periods of its growth. In reference to the latter, early ploughing, and afterwards obtaining a sufficient degree of solidity, may be considered as practically amongst the best means to be taken as a preventive. The effects of such a system have also frequently been apparent, not only as a protection from wireworm, but with reference to the ultimate value of the crops. The wireworm is generally most destructive on lands which have been fed through the summer, and also on others where the previous layer was not good. In these cases, shallow ploughing, as well as an additional quantity of seed, were recommended. Treading the land by sheep after the seed is deposited had also been practised, with a view of obtaining more solidity. When, however, the crop is affected in the spring, as (notwithstanding these precautions) is too frequently the case, the greatest benefit appears to have arisen from lightly breaking the soil, either by light harrows, or even raking, as early as circumstances may render practicable. A resolution was passed in accordance with these observations.—*J. D. Robinson, Assist.-Sec.*

Reviews.

The Application of Geology to Agriculture, and to the Improvement and Valuation of Land, with the Nature and Properties of Soils, and the Principles of Cultivation. By Nicholas Whitley, Land Surveyor. London. Longman, Brown, Green, and Longmans, 1843.

This work furnishes an example of the prevalent rage for giving to Geology, applied to Agriculture, credit for more than really belongs to it. The author says in his preface that he has been led to enforce the application of Geology to Agriculture, to which he hopes he has succeeded in demonstrating it to be no less valuable, as an auxiliary, than it has been in the development of mineral wealth; and he enforces the application of Geology to Agriculture, by such arguments as the following:—"But whilst improvable land is worth more than its apparent value, improved land is worth less. If the improvement is substantial and permanent, the full benefit of the increased yearly value is obtained; but this is not always the case; the drains may give way, or become blown, the river may burst the embankment, or a high and forced state of fertility may require such expensive manures to keep it up, that a lower standard of produce would prove the most profitable mode of culture. Geology leads us to detect these circumstances." We should be glad to know how. We had thought that questions as to the sufficiency of drains, the strength of embankments, or the economic value of a given mode of cultivation, were to be solved, not by the Geologist, but by the Engineer and Agriculturist. And so it is throughout, whether it be the classification of soils, the valuation of land, the improvement of its texture, and chemical composition by adding from other strata ingredients in which it is deficient—by draining and subsoil-ploughing, in order to rid it of superfluous moisture—by ploughing in a crop of Clover, in order to increase the humus in the soil; or whether it be the detection in improved land of plethoric symptoms indicating a tendency to apoplexy such as have been mentioned above—everything is ascribed to Geology. Such exaggerated pretensions must ultimately do harm by producing a reaction, and leading to a disparagement of the value of geological knowledge to those engaged in the valuation and improvement of land.

The application of Geology to Agriculture may be said to have commenced with the infancy of Geology itself as an inductive science. William Smith endeavoured to render those studies, by which he established the order in which the sedimentary rocks succeed one another, subservient to his professional duties as a land and mineral surveyor and agricultural engineer. But his views, as Professor Sedgwick has said, were in advance of the age, and he suffered, as many men of genius suffered before him, in his peace and his pecuniary prospects, from that which constitutes his glory among geologists, and earned for him the title of the Father of English Geology. Conybeare and Phillips, in their "Outlines of the Geology of England and Wales," blended with their descriptions of the different formations, notices of their agricultural characters. Dr. Buckland, in the opening of his "Bridgwater Treatise," took a rapid glance at the effects of the geological character of different districts of England, in influencing the nature of the industrial pursuits of their inhabitants, and, by consequence, their numerical amount, their wealth, the amount of health and longevity enjoyed by them, dependent on the salubrity or insalubrity of their employment, together with their moral condition as affected by that employment. Sir H. De la Beche, in his "How to Observe," remarked on the superior fertility observable at the junctions of strata, arising from the intermixture of their constituents, expressing surprise that effects so evident should not have oftener led farmers to seek improvement by similar artificial mixtures of adjoining soils. In his report on the Geology of Cornwall and Devon, he has devoted a chapter to the relations between the Agriculture and Geology of the various districts comprised in the survey—a field which had previously been broken by Dr. Paris in communications to the Geological Societies of Cornwall. Professor Johnston of Durham has more recently treated of the connection between Agriculture and Geology in his lectures on Agricultural Chemistry and Geology. But the first Agriculturist who studied Geology purely for its practical value in the discrimination, improvement, and valuation of land was Mr. Morton, who, in his work on soils, has given the results of his personal examination of every part of England, with that object in view, during a period of years. From these sources, as well as the works of Davy and Liebig on Agricultural Chemistry, and all that has appeared of late in the Journal of the Royal Agricultural Society, on draining and subsoil-ploughing, Mr. Whitley's work is drawn. The volume is a compilation throughout. To this we do not object when a work is fairly announced as such, for a compilation may be more useful than the many and expensive works of which it gives an epitome, and to which, as authorities, it refers for all its statements which are not original. But when it lays claim to originality, its pretensions cannot be allowed to pass as current coin without examination. The Author of the work before us says that his is "principally compiled from notes and observations made by him in various parts of the country, and that though he is conscious of its many imperfections, he feels emboldened in laying his facts and opinions before the public, by the consideration that the subjects here treated of have not received from practical men that attention which they deserve; and by a conviction that, at the present time, when artificial manures are so extensively used, it is of especial importance that the attention of all parties connected with Agriculture should be directed to some more accurate data from which to deduce the value of land, than that which a surface view, abstractedly considered, affords. The soils which occur in the west of England are those which are most fully and particularly described." There is, as we have said, scarcely anything in the book which is the result of original observation. Even for his descriptions of the West of England, that is, of Cornwall and Devon, he has recourse to Paris and De la Beche, sometimes with, sometimes without acknowledgment. He has gleaned, industriously enough, in every field, making notes and observations, no doubt, of what he read, in whatever part of the country he happened to be, but he has not always been satisfied with legitimate gleaning, making free, occasionally, with the sheaves, and stating, as his own, the facts and opinions of others. Like most gleaned corn, too, the sample is unequal, occasionally containing a mixture of defective grain, with that which is sound—of old and new theories without attempt to discriminate between them. Thus, for instance, at p. 115, he ascribes, with Liebig, the exhausting effects of Corn-crops to the large quantity of the alkalies which they extract from the soil, and the beneficial effects of Turnips and other fallow crops, to the small quantity of inorganic food which they require; while in the Appendix A, we have a table of the constituents of plants, from which, if Mr. Whitley will take the trouble of making the calculation, he will find, that while four quarters of Wheat and 3000 lbs. of Straw take from the soil little more than five pounds of potash and about the same quantity of soda, a crop of Turnips, weighing 25 tons, or 56,000 lbs., will take up 40 lbs. of potash and 61 lbs. of soda. With silica, however, it is quite the reverse. The Wheat crop contains full 93 lbs. of it, and the Turnip crop not more than 20 lbs. Thus a bare fallow, or a fallow crop not requiring silica, may operate beneficially by the time which it affords for bringing the slowly soluble silicates of the alkalies into solution, and thus presenting the cereals with silica, not potash, in a form capable of being assimilated by them. The author is likewise involved in similar inconsistencies from attempting to adopt both of the opposing theories respecting the assimilation of carbon by plants. We are told, for instance, p. 62, that "although humus is only slightly soluble in water, humic and ulmic acids, which are modifications of humus, unite and form soluble compounds with alkalies. Alkaline earths exist in the soil in sufficient quantities to form such compounds. It is therefore probable that humus not only forms a source of carbonic acid, but also enters into plants in a liquid compound through their roots." At p. 107 it is said, that "decayed animal and vegetable matter (humus) is of the first importance in manuring. Without its presence in the soil, the application of mineral manures will be of little service. If it does not exist naturally in the soil, from the decay of vegetation, it must be supplied artificially." At p. 108 we read, "It appears that three-fourths of the substance of plants usually cultivated is derived from the air, and it is on this fact that the principle of green manuring is founded. If a crop of clover be grown, and ploughed in when it begins to flower, it will give to the soil four times the amount of humus which it extracted from it. Land which is rich in the inorganic food of plants, may, in this manner, be furnished with a proper quantity of humus."

In taking a view of this plan for improving land from a practical point, we think it would be found much more profitable, having obtained such a crop of Clover, to feed it off on the ground with sheep, than to plough it in; and that such a proceeding would be equally beneficial to the land.

Notwithstanding these defects, however, Mr. Whitley's compilation, though somewhat slight and superficial, is not badly made. We have no doubt he will find the knowledge which he has acquired from the works he has read useful to him in his profession; whether that which he has to impart was not be better learned from it Morton

on Soils," and "Johnston's Lectures on Agricultural Chemistry and Geology," admits of a question. His work, however, may fall into the hands of those who would not have purchased the above volumes, and it may induce others to commence the study of the subject of which they treat, who will not be satisfied with the taste Mr. Whitley has given them of it, but will be led to drink at the fountain head. At all events the reputation of being a geologist and a chemist will now be as advantageous to the author, in his profession, as it would, a few years ago, have been detrimental to him; and we heartily wish him success.

In the following sober and judicious summary of the benefits to be derived from Geology in the improvement and valuation of land we fully concur. We give it as a specimen of Mr. Whitley's most successful manner of treating his subject:—

"1st. Geology offers to the practical Agriculturist essential aid in affording the means of definitely describing and classifying the various soils, thereby enabling him to apply to the land he cultivates those means of improvement found by experience to be suitable to any particular soil. 2d. Geology enables us to infer, from the mineral constituents of the parent rock, the chemical composition of the soil, and hence, to select such plants as may be most adapted to it. 3d. Geology points out the causes of fertility or unproductiveness, with the manure generally adapted to any particular soil, and the means by which waste land may be effectively reclaimed. 4th. Geology is of essential importance to the land-valuer, not only furnishing him with the information stated above, but enabling him to distinguish temporary fertility or exhaustion of land from its natural productiveness, and supplying him with data from whence he may estimate with some degree of certainty the value of the unexplored mineral wealth."—*E. W.*

Miscellaneous.

Agriculture in France.—On Monday the Central Congress of Agriculture opened at the Luxembourg its first session, the duration of which is fixed by the rules at one week; the Duke Decazes presided. More than 250 Agriculturists from different parts of France, a great number of Peers and Deputies, and members of scientific societies were present at the meeting. The bureau is composed as follows:—President, the Duke Decazes; Vice-Presidents, MM. de Gasparin, de Tracy, the Marquess de Torcy, and M. de Caumont. After having agreed upon all the questions to be discussed, the Congress entered upon those of Agriculture, Education, and Experimental Farms. Several able speeches were delivered. The members then formed their committees, and adjourned at half-past four till the following day.

Caution to Farmers.—Last week, four bullocks belonging to Mr. Lee, of Neopardy Farm, Crediton, died suddenly, without apparent cause. Mr. Reed, veterinary surgeon, found, on searching their stomachs, a quantity of the common Yew, mixed with the other food. On opening the skull, the membranes of the brain appeared in a very congested state, the poison having acted on the brain and nervous system, producing symptoms resembling apoplexy. A few days before, Mr. Lee had cut down a Yew tree, and two or three of the faggots were left where the animals had free access, and having been for some time deprived of green fodder, they ate it with great avidity.—*Western Luminary.*

Guano from Africa.—We have this morning seen a private letter from Liverpool, in which is the following important information:—"The first vessel from Africa with Guano arrived here yesterday afternoon—the Levenside, with 400 tons, full cargo. She reports a great number of vessels, some loaded, some partially so, riding off the island, and from the information which I have been able to receive, we shall shortly have a very large quantity from that quarter. The Levenside's cargo is on Glasgow account, and the captain set off for Glasgow a few hours after arrival at this port." We find from the Clyde shipping-list that the Levenside sailed from the Clyde on the 20th of September, having cleared out for Valparaiso, and comes to Liverpool from the island of Angia Pequena, coast of Africa.—*Ayr Advertiser.*

Notices to Correspondents.

RURAL CHEMISTRY, By Edward Solly, Esq., F.R.S., Experimental Chemist to the Horticultural Society of London, Hon. Mem. of the Royal Agricultural Society, and Lecturer on Chemistry at the Royal Institution, has been reprinted from the *Gardeners' Chronicle*, with additions, and may be had of all booksellers, price 4*s.* 6*d.*

OUR CORRESPONDENTS will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

COMMUNICATIONS from the following CORRESPONDENTS are in type, and are only waiting till room can be found for them:—*J. J. Mechi, Woodend, D. C., A. Hurtubise, J. Steele, R. Spooner, P., F. Davies, Northumbriensis, An Old Subscriber, J. Drummond, F. Singer, W. Billington, W. B. Booth,* and *G. Anderson.*

CHEAP WATER-POWER. — *Anonymous.* — The cheapest water-power is one invented and patented by Mr. T. Burstall, manufactured at the Udey Iron Works.

CONVERSION OF SULPHATES OF POTASH AND SODA INTO CARBONATES.—*Veritas.*—It is an expensive process, requiring an apparatus of furnaces, &c., &c.

CURRAN OF CROPPING.—*J. L. T.*—We should think that one-half your farm being in Grain crop, the other half might be cropped as follows:—1-3rd Clover, 1-6th Swedes, 1-6th Carrots, 1-6th Mangold Wurtzel, 1-6th Potatoes. Supposing you have 12 fields, your rotation would then be thus:—1 Wheat, 2 Swedes, 3 Wheat or Barley, &c sown down with Clover-seeds, 4 Clover, 5 Wheat, 6 Potatoes, 7 Wheat or Barley, &c., 8 Mangold Wurtzel, 9 Wheat or Barley sown down with Clover-seeds, 10 Clover, 11 Wheat, 12 Carrots. We believe by crossing the Down ewe with the Cotswold ram you will obtain as useful a stock of sheep as any one who intends to grow *fat mutton* can obtain. Thanks for your instructive letter. The per centage of potash given in your analysis is so great as to make us doubt its accuracy.

EXTIRPATION OF THE REED.—*J. Mac., Hillsborough.*—Drain the land, and this plant will ultimately die out of it. We doubt the efficacy of specifics for particular weeds, such as the application of salt, &c. Many thanks for your voluminous paper.

FARM ACCOUNTS.—*A Beginner.*—Put the *whole real value* of everything that belongs to you, live stock among the rest, to credit. More on this subject hereafter.

FIXER OF AMMONIA.—*A Subscriber.*—Sulphuric acid. Put it by degrees into the tank till effervescence stops.

GRASSES.—*A Novice.*—Messrs. Drummond and Son recommend a bushel of Perennial Rye-grass, 6 lbs. of Timothy, 6 lbs. of Meadow Fescue, 3 lbs. of hard ditto, 3 lbs. of Meadow Foxtail, 3 lbs. of Cocksfoot, 3 lbs. of Cow-grass, 6 lbs. of White Clover, as seed for one acre.

GYPSEOUS MARL.—*A Subscriber.*—We think it would be a most valuable top-dressing for Grass. Try ten cubic yards per acre, uniformly spread.

INSECT-KILLING MANURE.—*W. Cormack.*—We will publish the well-authenticated results of experiments, but cannot insert such a general and apparently extravagant statement as that you send.

LIME.—*G. B. M.*—Lime has been applied on the siliceous soils of Whitfield-farm before scarifying the Turnip land in March for Barley, before ploughing Clover-lea in Oct. for Wheat; and on Oat, Wheat, and Barley-stubble in autumn for the fallow-crop of the following year, and in all these instances with *uniformly* good effect.

LUCERNE.—*G. B. F.*—See Home Correspondence.

MANGOLD WURTZEL.—? & J.—Mid-April is the proper seed-time. We shall refer to the subject shortly.

MANURES.—*A Beginner.*—Your compost will be benefited by being soaked with liquid manure;—what compost would not?

MARKETS FOR YEARLING CATTLE.—*J. Clark.*—Barnstaple fair, Devonshire, April 21, Sept. 19, for Devon; Steyning fair, Sussex, June 9, for Scotch cattle; Hereford fair, July 18, and Oct. 22, for Hereford; Abingdon fair, Berks, Aug. 5, Sept. 19, for various breeds; at Barnet fair, Herts, April 8, 9, 10, for Scots, or anything you wish.

MARKETS.—Thanks for your suggestion, but we cannot at present adopt it.

MURRAIN.—*Anonymous.*—Your question will be answered if you will inform us which you mean—that usually called "the epidemic," which affects the feet and mouth; or the formidable disease of the chest termed pleuro-pneumonia.

NO. OF ACRES FOR ONE MAN'S EMPLOYMENT.—*W. P.*—It depends on the soil. One man can manage with the spade, 8 or 10 acres of light soil.

POND-MUD.—*L. B. W.*—Mangold Wurtzel and Cabbage will grow luxuriantly on your land. You could hardly do better. Apply wood-ashes to the land before sowing your grain crops, in September for Wheat, and in March for Oats and Barley, previous to harrowing before the drill. 40 bushels an acre might then be applied.

PRODUCTIVE BARLEY.—*O. M.*—Your notice is an advertisement.

SALT.—*Agricola.*—With the number of yards of ditch-scourings you intend to put on an acre, mix 1 cwt. of salt. Do not attempt to kill the weeds with that, lest in your success you have to lament the death of more valuable plants also. The hoe is the true remedy for weeds.

STEEPING SEEDS.—We believe that Mr. Campbell sells a liquid for Turnip seed. We shall be glad to hear your results.

STEAMING APPARATUS.—*A Subscriber.*—Potatoes are almost the only root generally steamed. Parsnips and Carrots are very well, when steamed for pigs; and Swedes are sometimes steamed for cattle. We never advertise tradesmen; it would subject us to stamp-duty. Most machine-makers manufacture a steaming-apparatus.

SWEDES.—*C. G. Sidy.*—Though we have heard it often, yet we do not *know*, if success attends general transplantation of young plants instead of sowing; therefore we do not like to advise. Try it on half an acre this year, and if it succeeds try a larger extent next. It has the advantage of hindering attacks of fly &c.

TOLLS.—*W. C.*—We cannot advise our correspondent without seeing the local Act regulating the tolls. If he will furnish us with a copy of it we will endeavour to give him the information which he requires. We believe that local Acts universally provide that a person who has paid a toll shall not be liable to a second on the same day, but the right to claim the exemption in general depends on the wording of the particular Act.

*** As usual, many communications have been received too late for answering this week.

Markets.

SMITHFIELD, MONDAY, Feb. 26.—Per stone of 8 lbs.

Best Scot., Hereford, &c.	3s 10 to 4s 2	Best Downs & Half breds	4s 0 to 4s 6
Best Short Horns	3 6 3 8	Best Long wools	3 8 4 0
Second quality Beasts	3 0 3 2	Ewes and second quality	3 4 3 8
Calves	4 0 5 0	Pigs	3 0 4 4

Beasts, 2811; Sheep, 24,560; Calves, 83; Pigs, 327

Our supply of *Beef* to-day is very small, and there is an advance in the best qualities of 2*d* per 8 lbs.; some few Short-horns have, perhaps, made 3*s* 10*d* per 8 lbs., but cannot be quoted as a general price. The trade is still dull, but the shortness of supply causes all to be sold off. The Mutton trade is very heavy; the best small Downs support our former quotation, large Downs are a slow sale at a little less money, and Long-wools are fully 2*d* per 8 lbs. less than last week. Veal trade is steady. Pork very heavy, and it must be superior quality to make our highest quotation

FRIDAY, March 1.

Although we have a short supply to day, it is difficult to maintain Monday's prices; there is, however, no quotable difference. The trade is remarkably dull, the demand on a Friday being generally so very small through Lent. The only brightness we can at all discover is in the Veal trade—the best quality being scarce, they are readily sold at 5*s* per 8 lbs. Pork is lower.

Beasts, 437; Sheep, 2189; Calves, 124; Pigs, 280.

41, West Smithfield.

POTATOES.—SOUTHWARK WATERSIDE, Feb. 26.

THE weather during the past week has been much like the preceding one—remarkable for its changeableness. The market has been supplied from most of the shipping districts since our last Report, but by no means liberal, yet fully equal to the present demand. The information received from most of the principal shipping districts of the scarcity of Potatoes imparts firmness to holders of the best samples, but it does not ingure the retailers to purchase beyond their present wants; they considering that there are plenty of Potatoes left to supply this market, at the present languid demand, as the advance in price has ceased a decrease in the consumption.

WOOL.—BRITISH, FRIDAY, March 1.

THERE has been hardly so much business doing in our market during the past week. Those parties who have been desirous of forcing sales have been obliged to submit to a reduction in price, but, upon the whole, we think prices may be quoted the same as last week. All parties are looking forward anxiously to the approaching Wool Fair at Bristol, which will be held on the 6th and 7th March.

KINGSFORD AND LAY.

MARK LANE, FRIDAY, MARCH 1.—We had very little English Wheat fresh up for this morning's market; dry parcels, being scarce, were fully as dear; but a large proportion of that sold last week and on Monday was refused, in consequence of its bad condition, and could only be disposed of at a considerable reduction. The business in free Foreign was limited, but its value is maintained. We only heard of one sale of Bonded Wheat, in which we observe no alteration.—Barley is the turn lower.—Beans and Peas remain as last quoted.—Oats are a dull sale, and Irish 6*d.* per quarter cheaper.

KINGSFORD AND LAY.

COVENT GARDEN, MARCH 1.—Although the weather still continues changeable, the Market is well supplied, and trade begins to get a little brisker. Pine-apples have been more plentiful during the week; they are offered at nearly the same prices as quoted in our last Report. Little alteration has taken place in the prices of Grapes, which are still sufficient for the demand. The supply of foreign Apples has been well kept up during the week; but English ones are scarce. Some good dessert Pears are still offered; they bring nearly the same prices as last week. Oranges are improving in quality, and are very plentiful. Lemons are offered at from 1*s.* to 2*s.* per dozen; Chesnuts are selling at nearly the same prices as last week. A few ripe Strawberries are in the Market. Among vegetables Savoys are becoming less plentiful. Brussels Sprouts are still selling at nearly the same prices as mentioned in our last report, as are also Greens, which are plentiful. Carrots and Turnips continue to be pretty well supplied. Broccoli has been more abundant during the week; a large white variety is selling at from 2*s.* to 12*s.* per dozen. A slight alteration has taken place in the price of French Beans; they are selling at from 2*s.* 6*d.* to 3*s.* 6*d.* per 100. Asparagus, Seakale, and Rhubarb are plentiful, and are offered at nearly the same prices as last week. Celery is becoming scarcer. Cucumbers are a little reduced in price. Cut Flowers chiefly consist of Combretum purpureum, Erica Willmoreana, Burchellia capensis, Lachenalia tricolor, Acacias, Azaleas, Pelargoniums, Camellias, Primulas, Moss, Provence, and China Roses.

FRUITS.

Pine Apple, per lb., 6*s* to 10*s*	Almonds, per peck, 6*s* to 7*s*
Grapes, Portugal, per lb. 1*s* to 2*s* 6*d*	Sweet Almonds, per lb., 2*s* 6*d* to 3*s*
Apples, des., p. bush. 4*s* to 10*s*	Nuts, Spanish, per bushel, 14*s* to 15*s*

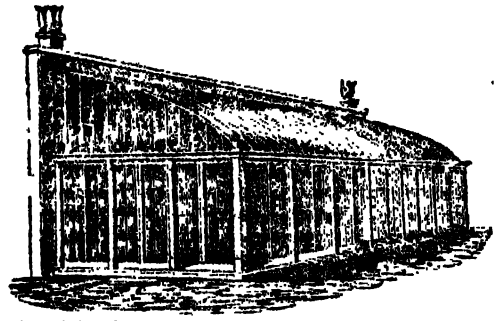
MARK POSTLETHWAITE.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, FACTORIES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal-works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.



D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

RENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance, can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of iron will be found cheaper than of any other material. MR. RENDLE, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

COTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c., &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL-ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices, in consequence of the present depressed state of the Iron Trade.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public, or Private Buildings, &c., with COTTAM'S PATENT, or ROGERS' BOILERS. After 15 years' experience, and having fixed upwards of 1000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale. For the convenience of those who wish to fix their own Apparatus, they have affixed the following low prices:—

Cottam's Patent Boiler, 18 inch . . .	£2 15s. 6d.
Rogers' Boiler, small size	1 17 0

Larger in proportion.

Hot-water Pipe, at 2, 3, and 4 inches, at reduced prices.

The TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

GARDEN ROLLERS 18 inches long, 24s.; 20, 44s.; 22, 50s.; 24 inches, 60s.; 26, 75s.; 28, 84s.; 30, 108s. each.

CAST-IRON KICKSTANDS, 2 feet six inches high, 5s. 9d. each.

Garden Engines, Mowing Machines, Garden Chairs, Superior Garden Tools of all kinds, Garden Vases and Pedestals in great variety, and every description of Horticultural Articles, Agricultural Implements, and Furnishing Ironmongery; Dr. Arnott's Stoves, Anglo-Belgian Cooking Stoves; Broiling Stoves. The above low prices being on account of the depression in the Iron Trade, are subject to future alterations.

STRONG IRON HURDLES, 3 ft. high out of the ground, 6 ft. long, with five horizontal bars, weighing about 36 lbs., 3s. 6d. each.

Light Cattle Hurdles, 3 ft. 6 in. high, weighing	42 lbs.,	4 0	,,
Strong do.	do.	do.	45 lbs., 4 4 ,,
Ox Hurdles, 4 feet high,		do.	60 lbs., 5 6 ,,

BEST WIRE, for STRAINED WIRE FENCING, at 9s. 6d. per bundle of 100 yards each. Uprights for ditto, 7d. each. The Improved continued, and every kind of Fencing, Fancy Wirework.

HAND-GLASS FRAMES for Cucumbers, &c., 18 inches square, 3s. 6d.; 20 inches, 4s. 6d.; 22 inches, 5s. 6d. each.

CAST-IRON FLOWER-STAKES, 4 ft. long out of the ground, 7s.; 4 ft. 6, 9s.; 5 ft., 11s.; 6 ft., 15s.; 7 ft., 20s. per dozen.

SHOW-ROOMS at the Manufactory, No. 2, WINSLEY-STREET, where every information may be obtained.

W. A. ROWLAND'S IMPROVED METALLIC WIRE, for WALL-TREES, VINES, and FLOWERS.

This WIRE having given great satisfaction, and its utility being, from the experience of several years, now fully established, the INVENTOR most respectively acknowledges the extensive patronage he has received, and as the season is now approaching when it will be in requisition, he respectfully begs to inform his customers that he has been enabled to reduce the List of Prices; and he assures them that no expense or exertion will be spared to render the article deserving of their continued approbation.

IMPROVED NAILS for fastening the Wire, being made so as not to cut or injure the Trees.

☞ Also, IMPROVED METALLIC LABELS and INDELIBLE INK, for naming Flowers, Trees, &c.

Observe, each article has the name of "ROWLAND" affixed to it. Sold wholesale and retail by Messrs. Dickson, Goodman, Chester, and retailed by all respectable seedsmen throughout the kingdom.

Garden Implements, Engines, Syringes, &c.—Chester, Feb. 14.

WIRE-WORK, HOT-WATER APPARATUS, GREEN-HOUSES, &c.

ST. THOMAS BAKER, MANOR-HOUSE, MANOR-PLACE, KING'S-ROAD, CHELSEA, Manufacturer of INVISIBLE WIRE-FENCE, to resist Grazing Stock, and rendered Rabbit-proof. WIRE-WORK in Trainers, Arches for Walks, Bordering, Flower-stands, Pheasantries, &c. HORTICULTURAL BUILDINGS, Green and Hothouses, Conservatories, &c. The same heated by HOT-WATER APPARATUS, on improved and economical principles.

Parties waited on in Town or Country, and Drawings and Estimates free. Work for the Trade as usual.

Ward's Cases, or Domestic Greenhouses.

GENUINE PERUVIAN & BOLIVIAN GUANO ON SALE, BY THE IMPORTERS, ANTONY GIBBS AND SONS, LONDON; GIBBS, BRIGHT, AND CO., LIVERPOOL AND BRISTOL. 47, Lime-st., Feb. 21, 1844.

ON SALE, in any quantity, PERUVIAN and BOLIVIAN GUANO, genuine as imported.—Apply to COTESWORTH, POWELL, and PRYOR, London; EDWARDS, DANSON, and Co., Liverpool; or WILLIAM J. MYERS and Co., Liverpool, the Importers.

GUANO, PERUVIAN, &c.—The above Manures, also Potter's Guano, Nitrates of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.

Lists of Prices, with Synopsis of mode of use, on applications to MARK FOTHERGILL, 40, Upper Thames-street, and 5, Railway Place, Mark-lane, London.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing a more rapid vegetation in Plants than any substance known. It may be had at Mr. LAWES' Factory, Deptford Creek, price 7s. per cwt. Phosphate of Potash, 15s. per cwt.

,,	Soda .	12s. ,,
,,	Magnesia 9s.	,,
,,	Ammonia 1s. per lb.	

MANURES FOR WHEAT, &c.

POTTER'S GUANO.—Result of an Experiment on Wheat, tried near Colchester—sown Nov. 1842, reaped August 1843. POTTER'S GUANO.—Seven bushels per acre gave 54½ bush. Grain. Daniell's Manure, 40 bush. per acre, gave 46 bush. Grain. Difference in favour of POTTER'S GUANO, 8½ bush.

Note.—The Daniell's Manure cost 3l. POTTER'S (present price) 2l.—Works 28, Upper Fore-street, Lambeth; sold by M. FOTHERGILL, 40, Upper Thames-street.

BEAUTIFUL FLOWERS.—POTTER'S CONCENTRATED LIQUID GUANO, for Flowers, Kitchen Garden Produce, &c. Sold by appointment, by SAVORY and MOORE, Chemists to the Queen, 136, New Bond-street, and 220, Regent-street, and can be had of most respectable Chemists and Seedsmen. Price 1s. 9d. the quart bottle, with directions.

DR. LINDLEY, in the *Gardeners' Chronicle* for 1843, p. 560, says—"POTTER'S GUANO will convert your desert into a paradise." And in the Number, Feb. 10, 1844—"POTTER'S GUANO is unrivalled."—Works, 28, Upper Fore-street, Lambeth.

HYACINTHS AND GROWING STOCK.

HUMPHREYS'S COMPOUND, applicable to all Greenhouse Plants, to Hyacinths and other Bulbs, and to promote the germination of Seeds. Sold in bottles 1s. 9d. each, by FLANAGAN and SON, Mansion-house-street; HURST and McMULLEN, Leadenhall-street; W. CLARK, Bishopsgate-within; SMITH, Islington Nursery; GRIMLEY and Co., Covent Garden; BATT and RUTLEY, 412, Strand; WILLIAM and JOHN NOBLE, Fleet-street; SMITH, Covent Garden; CHARLWOOD, Tavistock-row; W. J. NUTTING, 46, Cheapside; G. LAWRENCE, 18, Piccadilly; JOHN KERNAN, Great Russell-street, Covent Garden; LOCKHART, 150, Cheapside; SHUTTLEWORTH, Pantheon; MINIER, ADAMS, and NASH, 63, Strand; THATCHER and SON, Islington; J. FRYER, Clarendon-terrace, Camberwell; THOMAS ANSELL, Camden Town; THOMAS WATKINSON, Market-place, Manchester; T. S. KING, Rochester; W. E. RENDLE, Plymouth; DICKSON and Co., Edinburgh; PONTEY, Leeds; FISHER, HOLMES, and Co., Sheffield; P. LAWSON and SON, Edinburgh; J. THORNE, Shepton Mallet; and other leading SEEDSMEN in town and country. Wholesale Agents, DAVY, MACKMURDO, and Co., 100, Upper Thames-street, London.

THE NEW MANURE.

HUMPHREYS'S FARMERS' COMPOUND, presenting superior advantages to any Manure yet offered to the Public. It is rich in the Phosphates, Silicates, and Nitrogen, with certain new agents, so as to prove most economical and effective for Wheat, Barley, Pulse, Potatoes, Meadow Land, &c. Being manufactured on a new principle, this Manure *will not wash out of the soil* like Guano or the Salts, but with the mild and lasting qualities of the "Home-made" combines the most energetic fertilising chemical agents; adapted to all the purposes of Husbandry and Garden Culture, and unrivalled as a TOP-DRESSING for all Spring Crops. 12s. per cwt.—Wholesale Agents, DAVY, MACKMURDO, & Co., 100, Upper Thames street, London.

LIQUID MANURE.

PUMPS of a Superior Construction, fixed and portable, for Liquid Manure. Garden Pumps, Hydraulic ditto, and Pumps for deep wells. Also Pumps for Ships, Barges, Tanners, Soap-boilers, Brewers, &c. Well Digging and Boring executed. BENJAMIN FOWLER (late George Turner,) 63, Dorset street, Fleet-street.

HORSE POWER SUPERSEDED IN AGRICULTURAL OPERATIONS.

THE INVENTOR of a most efficient and economical SUBSTITUTE for ANIMAL and STEAM POWER, invites the attention of Capitalists to his important Discovery, particularly those interested in the prosperity of Agriculture.

A considerable amount of Capital being required, which must be obtained under great disadvantages, the advertiser is prepared to make such arrangements with any respectable party as would secure them from loss under all circumstances, and ensure to them a liberal share of the profits.

Prepaid letters, addressed Mr. ALEXANDER, No. 18, Easy-row, Birmingham.

THE URATE of the LONDON MANURE COMPANY, 5l. per Ton. It is with the greatest satisfaction, after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By promoting a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops. The Urate may be sown broadcast, or which is preferable, by the drill, at the rate of one ton to three acres, and it is desirable it should not be placed more than two inches below the surface. As a top-dressing for Wheat the Urate has been used with great advantage. Gardeners and Florists will find it very useful for Dahlias and other roots. Full particulars and Testimonials will be forwarded on application. Genuine Peruvian Guano; Phosphate and Sulphate of Ammonia; Gypsum and every other artificial Manure.

EDWARD PURKIS, Secretary, 49, New Bridge Street.

TO NOBLEMEN, AGRICULTURISTS, and OTHERS.

ANALYSES of SOILS, MANURES, &c., are conducted by Mr. MITCHELL, Analytical Chemist (late of the Royal Polytechnic Institution), No. 2, Victoria Cottages Rawley-road, Kentish-town. N.B.—A Vacancy now occurs for One House or Out-door Pupil.—Apply as above.

TO AGRICULTURISTS.—IMPORTANT DISCOVERY.

"Quid faciat lætas segetes."—VIRGIL.

THE CORN-PRODUCING LIQUIDS.—"One of the most extraordinary exhibitions in the yard (at the late Agricultural Show, Dundee), was that presented by Mr. JAMES CAMPBELL, of the Dundee Public Seminaries. It consisted of magnificent plants of Oats and Barley, grown from seed which had undergone a certain chemical preparation, and without the aid of any manure whatever.

"Such a mode of culture is at variance with all practical experience; but Mr. CAMPBELL declares that his prepared seeds, which have produced these strong, healthy plants, were sown by him on land which, to his certain knowledge, had had no manure of any kind for eleven years; and he declared himself quite ready to verify his statement by experiment, and said he was willing, at any time, to impregnate with his chemical preparations the seed which any member of the Society should send to him for that purpose, so as to enable gentlemen to satisfy themselves fully as to the efficacy of this wonderful mode of culture."—*Journal of Agriculture, October*, 1843.

In this discovery is actually realised that boast of science, which some years ago prophetically asserted, that the time would soon come when one might carry in his pocket matter sufficient to manure an acre of land.

After impregnation with these liquids, the seed possesses within itself elements which not only afford additional nourishment to the grain during the progress of germination, but communicate to the expanding vessels of the plant an aptitude to absorb food, both from the soil and the atmosphere.

Of one specimen of Oats exhibited, the average produce of 38 seeds was 1600 grains from each, or a total of 52,800 grains, weighing 48 lbs. per bushel.

The produce of Barley was an average of upwards of 500 grains from each seed sown; and of Wheat sown on 5th July, and taken up on 8th August, to be exhibited, the result was, that while the unprepared seeds gave plants with two, three, and four stems only, the impregnated grain yielded plants with nine, ten, and eleven stems.

The material for these liquids, at the following prices, may be had of the following Agents.

Wheat . . .	material for one gallon . .		2s. 6d.
Barley . . .	do.	do. . .	2 0
Oats and Grasses .	do.	do. . .	1 6
Beans and Peas .	do.	do. . .	2 0
Turnip and Rape-seed	do.	do. . .	2 6

Agents:—Messrs. GEORGE GIBBS & Co., 26, Down-street, Piccadilly, and Mr. EDWARD PURKIS, London Manure Company, 49, New Bridge-street, London; JAMES HAYDEN, Ironmonger, Warminster, Wilts; CROUCH & Co., Newcastle-on-Tyne; P. BRUCE, Hull; JOHN CAMPBELL, 5, Mersey-street, Liverpool; SAMUEL WALDIE, Carlisle; W. W. FYFE, *Agriculturist* Office, Berwick; and F. KARKEEK, Truro.

One-third, or even one-half less grain, is required for seed than is commonly used; and twelve gallons will impregnate eight bushels of grain; for the operation may be repeated in the residual liquid with additional measures of grain, as not more than one-tenth is absorbed in each operation.

Particular printed instructions for using the liquids will accompany invoices. No order under 20 gallons will be supplied.

1, Dudhope street, Dundee.

SUPERIOR SUBSTITUTE FOR TARPAULIN, &c.

C. MACINTOSH & Co. having made a considerable reduction in the price of the Patent India Rubber Covers for Carts, Waggons, Ricks, &c., beg to call the attention of Users of Tarpaulin and Oiled Sheets to the superiority of their manufacture as an effectual protection against wet, not liable to crack on being folded, and more economical than any other Waterproof cover.—22, York-street, Manchester; and 46, Cheapside, London.

THE LATE Mr. LOUDON.—The following Subscribers to the Works of the late Mr. LOUDON have been obtained since making up the List which appeared in the *Gardeners' Chronicle* of Saturday last:—

EDWARD BECK will be happy to answer any inquiries, either personally or by post.

GREAT YARMOUTH NURSERY, NORFOLK, 1844

YOUELL & CO.,

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN; HIS MAJESTY THE KING OF THE BELGIANS NURSERYMEN AND FLORISTS BY SPECIAL APPOINTMENT TO HER MAJESTY THE QUEEN DOWAGER

A SELECT CATALOGUE of the NEWEST and VERY BEST VARIETIES OF FUCHSIAS, VERBENAS, PETUNIAS, CHRYSANTHEMUMS, & ANAGALLIS, offered by YOUELL & CO.

YOUELL & Co., in submitting their Catalogue of FUCHSIAS for 1844, take this opportunity of drawing the attention of admirers of the above elegant tribe of plants, to their select and superb Collection. They have spared no expense in forming a selection of such as are really good, to the exclusion of many that are mere nominal varieties; and they will refer to the numerous testimonials of success which attended their mode of selection last season, collections for Amateurs for competition at the various Horticultural Exhibitions throughout the kingdom.

YOUELL & Co., being the parties who first sent out per post, with safety, these tribes of plants are desirous of calling attention to their advantageous method of executing orders, namely, that they will deliver them free of postage (on the receipt of a Post-office order), to any part of the United Kingdom, upon the following terms —

12 Extra Fine varieties, 12s the Selection left to Youell & Co
12 ditto ditto 21s, the Selection left to the Purchaser
50 Fine varieties . 40s, the Selection left to Youell & Co
50 Extra Fine ditto 60s, the Selection left to the Purchaser

With the exception of those marked thus *

The plants will be strong and healthy, and ready for delivery by the latter end of March, with the exception of those marked thus * (which will be ready in April), thus ensuring the Purchaser fine plants for competition in the ensuing season. Many of the varieties can be supplied now.

NEW AND SPLENDID SEEDLING FUCHSIAS

* "PUCHSIA LONDESVANA" This brilliant Fuchsia the entire stock of which is in the possession of Youell & Co is now for the first time offered to the notice of the public.

Its exceedingly large tube and sepals are of the most vivid vermillion, and excessively expansive surpassing in brilliancy any hybrid that has yet been raised. It was exhibited at the London Horticultural Society's Meeting, Regent street, and greatly admired, and was pronounced by all who saw Youell & Co's specimen plant to be the most dazzling object of this tribe they ever witnessed. The foliage and habit exceedingly fine, a most abundant bloomer, and will be found a desideratum to every collection. Plants will be ready for delivery by the first week in April, at 7s. 6d. per plant. Usual discount to the Trade, when more than six plants are ordered.

Youell & Co., in calling the notice of Amateurs and others to the following seedling Fuchsia, raised in their nursery beg to state that in the summer of 1842 they bestowed every care in hybridising the best varieties in cultivation, from which they succeeded in raising upwards of 3000 plants, to the flowering of which one house was entirely devoted last year. And although many varieties possessing superior claims to the attention of those cultivating this elegant tribe were submitted for the opinion of Dr LINDLEY, and most favourably noticed, yet Youell & Co feel that, in making a selection of the following six varieties, to which a most accurate description is affixed, will prove not only satisfactory to the purchaser but to themselves.

These will be ready for delivery in April next, and as the stock is very limited, early orders are solicited.

* "QUEEN VICTORIA" Tube and sepals smooth, of a bright vermillion, corolla stout, long, of a fine purple rose colour, forming a good contrast, and of fine texture, price 7s. 6d. per plant.

* "PRINCE OF WALES" Tube and sepals rosy vermillion the latter tipped with green, expanding well, and showing a fine purple of unique purple; price 7s. 6d. per

* "PRINCESS ROYAL" Tube and sepals bright red corolla rich and peculiarly bright in colour; price 5s. per plant.

* "MARCHIONESS OF NORMANBY" Flower large and showy flower, measuring four inches from the commencement of the pod to the termination of the petals, tube and sepals scarlet corolla open, having a tinge of purple on it; price 7s. 6d.

* "LADY ANNE PAUL" A flower of good form and substance, tube rosy red tube and sepals, the latter terminating in a decided green, corolla very large and stout, of a beautiful crimson purple; price 5s. per plant.

* "LADY WALSINGHAM" Tube and sepals smooth, of a rosy vermillion, the latter turn up and expose the white of the corolla, which is stout, and of a fine purple crimson; price 5s. per plant. When the six are ordered, they will be charged 21 10s. 6d. the set.

"FUCHSIA QUEEN" Quite new, very beautiful and not yet out, tube and sepals large and stout, of pure white showing a dark crimson corolla; price 10s. 6d. per plant ready in April next.

Fuchsia Seed, saved from the best varieties, 5s. to 10s. per packet, with Directions for sowing &c. &c.

With every other variety worthy of cultivation, that may be advertised by other parties after the publication of this list.

YOUELL & Co. are preparing a short treatise upon their successful mode of cultivation of the Fuchsia, which will be presented Gratis to Purchasers.

VERBENAS.

* "MONARCH" (Youell's) is a delicate creamy white, surpassing in its size and fragrance every other variety; the tufts of bloom measuring from 3½ to 4 inches diameter, and will be sure to give satisfaction. Price 5s. per plant.

* "BRILLIANT" (Youell's). This fine variety is of the most vivid scarlet, equal in this respect to "Melindria," the bloom, however, is three times the size and very fragrant, and will prove most desirable in any collection. Price 2s. 6d. per plant.

* "FENGANE" (Youell's) is a most interesting variety being a delicate lilac with a distinct white eye, flower large and fragrant. Price 2s. 6d. per plant.

* "SURPRISE" (Youell's) can be recommended as a variety completely novel and one that must be cultivated in every collection the colour being of the richest rosy crimson, or ruby, producing tufts of flowers of 3½ ins. in diameter, and delightfully fragrant. Price 5s. per plant.

The above four varieties have been selected from upwards of 2000 Seedlings and may be confidently relied upon as possessing superior claims and will be sure to give satisfaction; will be ready to send out in April next (post free). If the four varieties are taken, they will be charged 10s. the set.

By Order, Charles F. Green, Secretary, 27, Farringdon-st

EUCHARIDIUM GRANDIFLORUM.—A SPLENDID NEW HARDY ANNUAL.

WILLIAM MAY begs to offer the above new and beautiful flowering plant for the first time, seeds of which were kindly presented to him in 1843 by Capt. Widdrington, R.N., who introduced it from Monterey, California Territory, to St. Petersburg. It is twice the size of the Clarkia, and a brilliant dark rosy red, and very attractive in masses of that colour, blooming most part of the summer, and is remarkably hardy, the last 16 splendid in cultivation. May be had, price 2s. 6d. per packet, free by post.

William May, Seed Warehouse, Farnham, Surrey, Hampshire

WILLIAM MASTERS begs to call the attention of the Nobility, Gentry, &c., to his newly and well assorted COLLECTION OF GARDEN AND FLOWER SEEDS, which being principally grown under his immediate inspection, he can particularly recommend.

100 papers finest Annual Flower Seeds	:	24s. 0d.
50 do. do.	:	12 6
25 do. do.	:	6 6

If the selection is left to W. M.

Forwarded by Post without additional charge. POITEVIN'S ARTIFICIAL GUANO and CONCENTRATED LIQUID GUANO.

Exotic Nursery, Bayswater, near London.

Agents for Hamilton's New Pinks, (see plate in "Paxton's Magazine") "Sir Harry," "Lucretia," 2s. 6d.; President, 7s 6d Colossus, 7s 6d; Augustus, &c.; Confidence, 5s; Candidate, &c., and all the leading Varieties worth notice.

Verbenas—all the new varieties, Choice Dahlias, Carnations, Picotees, &c.; Auriculas, pollenated, Alpine granuliflora, &c. &c.; new kind, Cloth of Gold Variety of Nemophila discoidalis; New Pinks, Dahlias, Carnations—7s 6d, each. Cinerarias, all the choicest varieties. "Princess Alice Maude Strawberry, 6s per doz., this is considered the best Strawberry known. Prince Albert, 20s.; Myatt's Deptford Pine, 30s., Myatt's British Queen, 7s. per 100; and all the other well-known varieties. Agents for the sale of all the late Mr. J. C. Loudon's Works

FLOWER SEEDS—36 Packets, 10s.; 18 ditto, 5s., forwarded, postage free, to any part.—Apply to Mr. John Brown, Abbey Nursery, Stoke Newington, London. Any reference to species may be specified in the order. Payment by Post office order or stamps.

J. H. Brown has on sale an extensive collection of the most approved Plants for greenhouses and conservatories. Parties building large or small greenhouses can be well supplied.

LISIANTHUS RUSSELLIANUS.—A Packet of Seeds of this most Beautiful Plant, with Directions for Growing it successfully, sent free. The following observations are from Doctor Lindley, in the "Gardeners' Chronicle":—"This fine plant, introduced from Texas in 1838, is still unattainable in the hands of many good gardeners, yet we seem easily see no impediment on the exhibition tables near London, a succession of that the Plant may be grown well under proper management. Among the most successful cultivators of it is Mr. James Cuthill, Florist, Camberwell."

Remarks of Mr. Glendinning, the "Horticultural Cabinet":—"We visited Mr. Cuthill's establishment to see the Lisianthus Russellianus in its various stages, and the plants were in the greatest vigour, exceeding any thing we have ever seen before."

The true Beechwood Melon, sent by the Horticultural Society, 2s. 6d. Cuthill's Early Melon, 1s. 6d.; or the 2 packets of seed sent post free for 3s.

Also Cuthill's Prince of Penzance Scarlet Cloth, for Massey Carnation, 12s. per doz. "The best Magenta Geranium known."—Doctor Lindley.

Also a new broad-leaved Mauve-coloured Nemophila (Grenadier Pink), James Cuthill, Dunmore-hill, Camberwell, Surrey.

N.B. The Lisianthus plants are all sold.

NORWOOD FORESTER NURSERY.—ESTABLISHED 1818.

R. G. MARSHALL begs to submit to Noblemen, Gentlemen, and Agriculturists his GARDEN POTS, DRAIN TILES, &c., of the same excellent material which gave such general satisfaction during the long period his father had possession of the premises. They can be had as above at the lowest remunerating prices. Terms, cash or a reference.

BUSHELL'S Light Seedling Dahlia "EMMA."—Plants in May, 10s 6d Colour white, tipped with deep cherry; the petals, form, and centre, good; the largest, most constant, and free in flowering of any Dahlia yet propagated, and has obtained several prizes "Pet Rival" Plants in May, 5s Colour, purple maroon; fine cupped petal and free bloomer; exhibited in several winning stands last season. Kennington Rose, Plants in May, 5s; most constant Rose grown To be had of Messrs. Bushell, Camden Town; S. Girling, Stow market; F. and A. Smith, Hackney; and J. Bushell, 12, Hall place, Kennington-lane.

JOHN MILLER, surviving Partner of the late firm of Sweets and Miller, Nursery and Seedsmen, Bristol, begs respectfully to inform Nurserymen, the Trade, and his Friends in general, that he has commenced business as Auctioneer and Valuer of Horticultural and Agricultural Stock, &c., and hopes by strict attention to the interest of his employers, to merit their support. Letters addressed to John Miller, Portland House, Kingsdown, Bristol, will meet with immediate attention.—Bristol, May 6, 1844

TO THE NOBILITY, GENTRY, CLERGY, AMATEURS, AND OTHERS.

THE SUBSCRIBER begs to state that he is prepared to supply the undermentioned, viz.—

Cineraria, "The Queen of May,"—a beautiful sky blue, of shrubby compact growth, quite new colour, of fine form and large size, at 5s each

Cinerarias—12 of the most distinct and approved varieties for 20s

Fuchsias—25 distinct fine sorts, including his own seedlings, for 20s

Calceolarias—20 distinct and good sorts, of all shades of colour, for 20s.

Hollyhocks—fine strong one year-old plants from his best selected seed, 20s per 100.

Herbaceous Plants of the most showy varieties, correctly named, 100 sorts for 42s

Hardy Flowering, and Evergreen Shrubs, in 50 sorts, two plants of each, correctly named according to Loudon's "Arboretum Britannicum," at 42s per 100, including package

He will also have to offer in April a new Collection of beautiful Calceolarias, not yet sent out, a Descriptive Catalogue of which is in preparation, and will be forwarded to applicants. These are from his own celebrated Stock, and of the same breed as his Cal. "Lady Constable," so much in repute.

Seeds in packets of Hollyhock, Pansy, Picotee, Calceolaria, and Hybrid Fuchsia, at 1s 6d, and 3s each

TO THE TRADE, MARKET GARDENERS, AND OTHERS, he begs to state that he has yet to offer a few thousands of Gooseberries, and the large Red Antwerp Raspberries.—The Gooseberries are comprised in upwards of 100 of the most generally useful kinds in cultivation, and the Red Antwerp Raspberry is decidedly the best sort grown, for produce, size, and quality; both of which he will offer on very moderate terms, in quantity. The plants are young, clean, strong, and healthy, two and three years old.—Also Mac's new large late red "Victoria Currant," a dish of which was sent to and exhibited in 1843 at the Horticultural Society in Regent-street, London, some of the bunches of which measured 6 inches in length, and individual berries 1½ inch in circumference—12s per doz. New Black Bang-up Currants, 6s per doz. The usual allowance to the Trade on the Currants.

Woollen Net for protecting Fruit-trees from frost, of the best material, at 6d per yd.

Stove and Greenhouse Plants and Florists' Flowers of every description. Finest and Fruit Trees, Garden and Flower Seeds, of all the approved sorts. William May.

Hope Nursery, Leeming-lane, near Bradford, Yorkshire.

DAHLIAS.—KEYNES' REGISTERED BY PRESTON; DODD'S ORANGE PERFECTION, and DOWDING'S Nimia Mundi.—The Stock of these splendid DAHLIAS is in fine condition, and will be sent out after the 1st of May. A List of the Subscribers who have ordered the above splendid Plants, will be determined the 1st of April. Those who intend growing these varieties only, by giving their orders, secure the Plants the first week in May.—Salisbury, March 7, 1844.

TAPSCOTT RASPBERRY.

PATRONISED BY [illegible]

MOST [illegible]

OF [illegible]

LORD [illegible]

LORD [illegible]

TURAL SOCIETY [illegible]

YOUELL AND Co. [illegible] ing they [illegible] supply [illegible] valuable and much [illegible] extraordinary size of the fruit and [illegible]

Those to whom Y. and Co. sent it [illegible] their high admiration of its superiority over [illegible] and has been awarded several prizes from [illegible] exhibitions during the season, [illegible] rated in execution, drawing, [illegible] (see *Gardeners' Chronicle* of the 24th [illegible] opinion of it is as follows:—

"Tapscott Raspberry.—We have received [illegible] Youell, of Great Yarmouth, fruit of the Tapscott Raspberry, and we find its merits all that have been stated to [illegible] of excellence. The fruit that we have received [illegible] tately ripened, and of rich flavour, far surpassing [illegible] some other new and large varieties. The plants [illegible] and in long succession."

They also exhibited it [illegible] London Horticultural Society, [illegible] prize was awarded. It would [illegible] Youell and Co. to recommend it [illegible] confidence of the nobility, [illegible] continues in high perfection [illegible] and has maintained its pre-eminence [illegible] soils and situations, and supplies an [illegible] treatment of the old varieties.

Fine Canes are ready for delivery, and can be [illegible] to any part of the United Kingdom (on the receipt of a Post office order), upon the following terms:—

Packages containing 144 Canes	:	£2 2s. 0d.
Do. do. 72 do.	:	1 1 0
Do. do. 24 do.	:	0 10 6

Package included.

The usual discount to the Trade, when not less than [illegible] ordered.

*** Caution.—Y. and Co. beg to call the [illegible] Friends and the Public in general to the fact [illegible] pointed no Agents in London for the sale of [illegible] not be held responsible for its being [illegible] direct from their Nursery.

THE NEWEST AND VERY BEST FUCHSIAS, VERBENAS, PETUNIAS, ANAGALLIS, &c., FOR 1844.

YOUELL AND Co. beg to refer the Readers of the *Gardeners' Chronicle* to their Catalogue of the above, which appeared in this Paper of last week, and will be found to contain such varieties only as are worthy of cultivation.

Youell & Co. being the parties who first sent out, and got them with safety, these tribes of plants, are desirous of calling attention to their advantageous method of forwarding orders, namely, that they will deliver them free of postage (at the [illegible] Post office order), to any part of the United Kingdom, upon the following terms:—

12 Extra fine varieties, 12s., the Selection left to Youell & Co.
24 ditto ditto 21s., the Selection left to the Nurseryman.
50 Fine varieties 40s., the Selection left to Youell & Co.
50 Extra fine ditto 70s., the Selection left to the Nurseryman.

With the exception of Cuttings, [illegible] Plants will be strong and healthy, and ready for delivery by the latter end of March, with the exception of those marked thus * (which will be ready in April), thus ensuring the Purchaser fine plants for competition in the ensuing season. Many of the varieties can be supplied now.

YOUELL'S TOBOLSK RHUBARB, Patronised by Her Most Gracious Majesty the Queen, and many of the Nobility, 15s per dozen. For particulars of which see their Advertisement of the 16th November.

TWO NEW SEEDLING PICOTEES.—"Last Alice Pike," 10s 6d, and "Mrs. Beaton," 10s 6d. per pair.—These two splendid Picotees were raised by the Rev. J. Burroughes, of Lingwood Lodge Norfolk, and kindly presented by that gentleman to Messrs Youell & Co., for purchasing which see their Advertisement in this Paper of the 16th ult.

FINEST CARNATIONS AND PICOTEES.

YOUELL AND Co beg to refer the Readers of the *Gardeners' Chronicle* to their Extensive List, with Prices, of the above highly esteemed Flowers which appeared on the Advertising pages, 706 and 707, of this Paper, of October 12th, and will be found to contain every variety worthy of cultivation.

Fifteen best Blows		
12 pair of good Show Borts	:	£1 1s 0d
12 ditto fine ditto	:	1 10 0
25 ditto ditto	:	2 2 0
12 ditto extra fine and very superior ditto	:	3 3 0
25 ditto ditto	:	5 5 0

The selection being left to Youell & Co.

ARAUCARIA IMBRICATA.

YOUELL AND Co, possessing the most extensive stock in the country of this elegant Ornamental Tree beg to offer them on the following advantageous terms.—Fine robust 4 year old plants, 2 to 2½ inches high, 10s. per 100 or 70s. per dozen.

Fine Plants of CEDRUS DEODARA, 1ft. to 2ft. 6 in., 4s. 6d. each.

Great Yarmouth Nursery, March 7, 1844.

STANDARD CURRANTS, white and red, trained on a single stem 5 ft. high, like Standard Roses.—Any Nurserymen having any to sell may direct to A. Z., Spencer's Library, No. 314, High Holborn, post paid, stating size and price

1844.

A LIST OF CHOICE FLOWER AND VEGETABLE SEEDS, SOLD BY

WARNER AND WARNER, SEEDSMEN, No. 28, Cornhill, London.

Acacia lophantha		0s	6d
,, untimifolia		0	6
Aconitum variegatum		0	6
Achimenes rosea superba		0	6
*Alonsia grandiflora		1	0
Alstroemeria, in fine varieties		0	6
*Anagallis indubitata major		1	0
,, ,, grandiflora			
form		1	0
Anchusa, new hybrid, Russian		0	6
Antirrhinum hybridum, 24 shades of colour, mixed		0	6
Aquilegia glandulosa		0	6
Argemone grandiflora		0	6
Aster, extra fine German, 24 sorts, mixed, from imported varieties		0	6
Aster, collection of 24 varieties, as imported, most splendid		5	0
*Auricula, from fine named flowers, extra		1	0
Balsam, fine double Camellia flowered mixed		0	6
Balsam, double German, 12 splendid varieties		3	6
Blumenbachia insignis, a fine climber		0	6
*Boronia denticulata		1	0
*Brachycome iberidifolia		0	6
Cacalia aurea		0	6
*Calceolaria, shrubby and herbaceous, separate, saved from fine named vars. and newest kinds		1	0
Calempelis scaber		0	6
Calendrina grandiflora		0	6
*Calliprora, extra		1	0
Cenanthus aureus		0	6
Callopsis Drummondii, grandiflora		0	6
,, lutea		0	6
Campanula Loreii, blue and white		0	6
Campanula Trachelium fore pleno		0	6
*Campanula stricta, new and beautiful		0	6
Campanula pendula		0	6
Canterbury Bells, double blue and white		0	6
Carnation, from fine named flowers, extra fine		1	0
Catananche bicolor		0	6
Centaurea Americana		0	6
*Chorizema varium		1	0
,, spectabile		1	0
*Cineraria, from the newest and most approved varieties		0	6
Cistus helianthemum, for rockwork, mixed colours		0	6
Clarkia elegans		0	6
,, grandiflora, crimson		0	6
,, alba fimbriata		0	6
*Clerodendron speciosum		1	0
Clintonia pulchella		0	6
Collinsia bicolor		0	6
Collinsia verna		0	6
Cockscomb, new giant scarlet		0	6
Cockscomb, Brighton prize yellow		0	6
,, new dwarf		0	6
Collinsia rubra major		0	6

RANUNCULUSES, ANEMONES,
PELARGONIUMS, AURICULAS, CARNATIONS,
AND LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near Stockwell, respectfully informs Walworth, by Appointment Florist to Her Majesty, begs to inform the Nobility, Gentry, and Amateurs, that in consequence of the success he has had in the cultivation of the above flowers at his new Garden, he can offer them at very moderate prices. He would particularly recommend an early application to be made for RANUNCULUSES and ANEMONES, as they should not be planted later than the end of March to secure a good bloom. His Catalogue of PELARGONIUMS, AURICULAS, and NEW PLANTS, is now ready, and will be forwarded by post on application. The Trade supplied.

MELON SEEDS.—A very liberal Remuneration will be given for some PERFECTLY PURE AND GENUINE SEEDS of the under-named Melons, or Seeds procured the last year direct from China, Cabul, and Candahar, will be given in exchange:—Striped Roccoinan, Daree, Gorse, Gernala, Melon of Gerger, Nukshevan, Sweet Melon of Ispahan, and Italian Green-flesh.

Application to Mr. G. Mills, Gardener, Gunnersbury Park, Acton, Middlesex.

The Gardeners' Chronicle.

SATURDAY, MARCH 9, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS

Wednesday, March 13	Society of Arts	8 P.M.
Tuesday, March 19	Horticultural	3 P.M.
	Linnean	3 P.M.
Wednesday, March 20	Microscopical	8 P.M.

"With the exception stated below, trees imbibe from every part of them which is exposed to moisture, and give off (transpire) from every part of them which is exposed to drought. The root is the part which is constantly exposed to moisture, and which furnishes the constant supply of sap to the tree. That part of the root which is universally believed to imbibe no moisture, the woody part, is the only part which does imbibe moisture; *and that part of the root which is universally believed to be the only part which does imbibe moisture, the unripe ends or fibres, is the only part which does not imbibe moisture.*"

Such is the startling declaration of Colonel Greenwood, whose book on planting we noticed a fortnight since (p. 118). On the one hand, it is the opinion of a man who has evidently paid attention to practical foresting, and has indulged in the good habit of thinking for himself; on the other, it is entirely opposed to the views of preceding writers, and strikes at the root of some of the most solid observations in vegetable Physiology. It has, therefore, a double claim on our attention.

We will not stop to inquire at what time the term "spongelet" was first applied to the young and tender points of the roots of plants. It will be sufficient to state that, with the exception of a few ill-informed persons, who fancied the spongelets were special organs, everybody from the days of Duhamel up to those of Colonel Greenwood, has recognised in those spongelets the most powerful of the absorbent parts of plants. Senebier, a Swiss physiologist, proved the fact by the following experiment:—"I placed," he says, "in water, a plant of Radish, inserting only the point of the root; it remained fresh for many days. I bent the root of another Radish, without breaking it, and plunged the curved part in water, so that the leaves and the point of the root were above the edge of the vessel employed: the leaves at first flagged, but as soon as the point of the root was introduced into a tube of water, they recovered their original freshness. I repeated the same experiment, with similar results, on several other plants, having roots flexible enough to be bent, and sufficiently clear of side rootlets, to render the experiment trust-worthy."—*Physiologie Végétable*, vol. i. p. 311. Duhamel had previously remarked that many plants suffered more from being planted under old Elms when they were 4 or 5 feet off than when they were close to the trunk; "because, at the former distance the fine fibres of the Elms were able to exercise their sucking force, while, near the trunk itself, the old roots were inactive." This in fact is so well-known a circumstance, that it could hardly have escaped observation, if Senebier had never published his Physiology. Let us take a few instances about which there can be no doubt. In a fruit border the wall trees become too luxuriant; the gardener cuts off the points of the roots where the great act of absorption is going on, and so for the moment checks them. An old tree is exhausting the soil; where is manure added,—round the trunk, or by breaking up the soil at a distance from it, and introducing the manure at that place? We think there is but one answer to that question. It is true that we have seen ignorant people pouring water round the trunk of an old tree, in the summer, in the hope of reviving it; but they might almost as well have poured the water in another county. And again, we all know that plants which are growing in pots may be transplanted at those seasons with safety, when no precautions would enable the same plants to live if taken out of the ground. In that case, the preservation of the young and tender roots is undoubtedly the explanation of the uniform success attending pot-transplanting in summer.

But experiment is hardly necessary to show that the young and tender fibres of plants are the most powerful of their absorbing surfaces. It is an undoubted fact that all vegetable tissue allows water to pass through it with a facility proportioned to its youth. The younger is vegetable tissue, the thinner it also is, and the more easily penetrated by fluids. As it grows old it thickens, hardens, and even dies: and with that thickening, hardening, and dying, does its power of transmitting fluids diminish. The youngest parts of the roots of plants are the spongelets; next in age is the part behind them, or the small fibres; and the oldest are the large thick roots; therefore the most absorbent are the spongelets, next the smaller fibres, and last the large thick roots.

Let it not be supposed from these statements, that we deny all power of absorption to the surface of old roots; on the contrary they no doubt do absorb to a certain extent; and Col. Greenwood is right when he says that "trees imbibe from any part which is exposed to moisture." But the question is not, whether the roots of plants absorb by their points alone, or by their old surfaces; it is, whether they absorb fastest by the one or the other: and to that there can only be one answer. Col. Greenwood says that in transplanting "the supply must be equal to the demand; if not, scarcity will ensue." and nothing can be more true; it is the fundamental axiom of transplantation. And that being so, it is obvious that the supply of food to plants will be greatest where the most powerful absorbing parts are preserved. Those parts are the tender fibres and their spongy extremities.

It is superfluous to examine the evidence produced by Col. Greenwood to prove that all parts of plants in contact with moisture will absorb it, because nobody denies that fact. The true question is, which parts will absorb it fastest, so as to ensure a supply equal to such demand as may be made? Physiologists say the spongelets; Col. Greenwood undertakes to prove that "roots do not imbibe at all from the small sponges (spongioles) which are *supposed* to exist at their ends." Let us consider the nature of his proof.

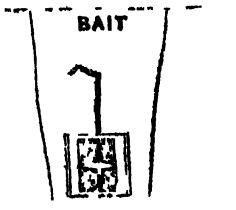
He begins, as will be seen from the passage just quoted, by denying the very existence of spongelets. But we presume that fibres must have an extremity; as they grow by additions to the extremity, that part must be the youngest; and as spongelet is merely the technical name of the young point of a root, a spongelet must have a real existence. We may therefore consider the existence of spongelets to be sufficiently proved. The next argument is founded upon the roots of Horse Chesnuts growing in water. It was found that "where the root was cut off when several inches long, the plant would still grow, and would continue to throw out fresh roots as fast as they were cut off." But this proves nothing further than that the Horse Chesnut seed, when in contact with water, is capable of absorbing fluid fast enough to live until the loss of the rootlets can be repaired. It surely does not prove that the young fibres had no action. Then it was found that "if the plant was divided from the seed, by cutting the *umbilical bands*, it died, though the root was perhaps twice the length of the plant." We are not sure whether we understand what is meant by "umbilical bands;" but if the bases of the seed leaves (cotyledons) are intended by the expression, we still find no proof in support of Col. Greenwood's theory; for we all know that seedlings are incapable of living in the absence of their cotyledons. The experiment shows that roots cannot live in the absence of leaves, or their equivalents, which the cotyledons are; but by no means that the young fibres of roots are useless.

Beyond this experiment we find nothing in Col. Greenwood's book in support of his novel views, except the well-known fact that trees may be transplanted successfully when the fibres are for the most part cut off. In those cases, however, it will be found that, in the first instance, the wounded ends themselves absorb fluid until the organisable matter lodged in the vicinity is called into action and has formed fresh fibres. And the notorious danger of trusting to the transplanting of trees with greatly mutilated roots lies in the chance that the leaves will draw upon the roots for fluid faster than the roots can provide it, and that thus the supply should *not* be equal to the demand.

Let no one therefore imagine, because it is possible, under very favourable circumstances, to transplant trees with few small fibres attached to them, that it is a practice which can be in any way recommended for adoption. We must never neglect the probable, from a blind reliance upon the possible.

BARRENNESS IN THE FIG.

Much inquiry has taken place lately about the management of Fig-trees in our moist climate, and I do not wonder at it; for of all our fruit-trees the Fig seems most difficult to bring under system. When, however, the bright and dry climate of the East, where it is indigenous, is taken into consideration, and compared with the climate of Britain, together with the rapidly-absorbing powers of both the roots and leaves of this plant, the wonder will be much diminished.



Short-jointed wood is allowed on all hands to be the criterion of fruitfulness in most fruit-trees; this is particularly so with the Fig, and of course is quite incompatible with luxuriance. Now, few persons that have any practical knowledge of its habits will venture to put manure of any kind within its reach in open-ground culture; animal manures, especially, are entirely out of the question. However, it is not enough to refrain from the use of manures; even plain loam, with liberty to range, is by far too powerful a stimulant for the average heat of our summers. I have some Fig-trees on a south wall that were old trees when the following detail of operations took place: they had grown with excessive luxuriance for many years, and seldom bore fruit; the leaves were twice as large as they should be, and the internodes between the buds on the young shoots were from four to six or eight inches in length, whereas in fruitful Figs the internode is sometimes barely perceptible. These Fig trees, in consequence of alterations, had to be removed, and when they were replanted I placed a temporary wall at two feet distance from the trees, and filled the inclosed space with maiden soil—not the turf, but taken from under the turf; and in addition to this, I formed a substratum of bricks, allowing only nine inches of soil in depth. The Figs were taken up in November, and laid in amongst some rubbish until the end of March; it had been a most severe winter, and the trees when planted were to all appearance nearly dead—the bark was much discoloured. However, they grew after some weeks, and they are now again too luxuriant, although they have borne much better since the operation.

From this, and many other observations I have made for years, I have no doubt that it would be much better for the Fig out of doors, as well as for some luxuriant Pears, to mix a very considerable portion of stone, in masses of some size, with the soil, when the border is prepared. I should think that equal portions of sound loam, rough lime-rubbish, and masses of stone, trod well together when dry, would be an excellent compost for Figs, or even for many tender Pears. The rapid action of the root must be impeded by some means—and what more in accordance with nature than acting thus on the texture of the soil? If this were done, we should not hear so much about disbudding and systems of pruning. The Thorn-tree, with its profusion of fruit, ought to teach us a lesson—growing, perchance, on a solid and shallow bank of dry soil; here the annual growth is in proportion to the light and heat of the climate, and the consequence is, extensive and perfect elaboration of the sap.—*Robert Errington.*

ON TRAPPING VERMIN DESTRUCTIVE TO GAME.

Some gardeners have to act as gamekeepers, especially those who are employed by gentlemen whose incomes are too small to allow them to keep men for the sole purpose of preserving or of killing game. Though many gardeners can kill, yet they sometimes cannot preserve game, that is to say, they do not know how to destroy vermin. To such, a few remarks on the trapping of vermin that destroy game may be useful.

They are generally taken in what gamekeepers in the north call "wears." A wear is only a few twigs stuck in or laid on the ground around a bait and a trap, so that the animal to be taken cannot reach or take away the bait without going over the trap. When a wear is against a wall, fence, tree, or bush, it is usually in the form represented in the accompanying figure. If it is made in an open field, it is oval. I have said that a wear is made of twigs, but it must be made of whatever is about the spot on which the bait is laid, whether it is Chickweed, Ragweed, Long, bushes, or rotten branches. A wear, about a foot long, 9 inches broad at the back or wall, 6 inches at the mouth where the trap is set, and 6 or 7 inches high (uncovered), is large enough for the polecat, weasel, &c.; but one to entrap a fox ought to be 2 feet long, 18 inches broad at the back, and one-third narrower at the mouth.

Almost all sorts of carrion may be used as baits, which ought to be pegged down; the traps should be covered with the same material as that amongst which they are set; that is to say, if they are placed on sand they must be covered with sand; if on Moss, with Moss; or if amongst rotten branches, with them.

The Fox is exceedingly wary and subtle, and avoids everything that has any appearance or shadow of danger. On the side of an avenue or in a strip of plantation, if there is a foot-path running from the one end to the other, it is a good place to form a wear for this animal. He may also be taken in wears near rivers, streams, standing water, spongy marshes, or Furze covers; and without wears, by hanging a bait against a wall, fence, or tree, within his reach, and setting a trap 15 or 16 inches from the wall, &c. Several traps around the mouth of his hole or "earth" may likewise take him in going in; and if it is certain that he is in, a trap ought to be set inside, and a few branches put over the mouth of his "earth," that he may come upon the trap before he is aware. If the hole is not darkened, it is probable that he will come out under the trap. When it is known which way he comes from his cover, the best plan is to fasten a bait of an animal that has been some time dead, so that the effluvia may be smelt at a distance, to a stick or string, and trail or drag it round a field, and then into the centre of it, where the bait ought to be half buried, pegged down, and three traps set around it. This plan is often attended with success. Foxes, badgers, and other vermin are sometimes taken in pitfalls, but as it requires a little time and labour to make them, and as men and cattle may fall

take them, I shall not recommend them for anything but for the domestic cat. The best places to dig pitfalls for them are near his "earth," and on a path that goes from one plantation or cover to another.

The Polecat, Stoat, and Weasel.—These vermin can be taken in wears, steeltraps, and counterfeit or false burrows. Wears should be near rivulets, large heaps of stones, old walls, or rubbish of any kind. Where two walls or fences join is an excellent place for a boxtrap. In the absence of a boxtrap, four boards, wide enough to let common traps spring, may be nailed together, and made to pass through a wall or fence, and common traps set at each end of it with a bait in the middle. Traps placed at the entrances of their holes, or against holes in stone fences through which they pass, will take them. False burrows should be made at the bottom of hedges, &c. By hanging baits against walls, banks, fences, and gateposts, and placing traps under them, they may be taken. Almost all vermin that destroy game often pass through gates.

The House or Domestic Cat will put her foot on an uncovered trap to reach a bait on a gatepost. Puss is easily taken in wears; but by using "a charm" she is much more easily captured. This charm is the root of the shop Valerian (Valeriana officinalis). One writer on British plants says that "cats, and especially rats, are fond of the roots of this plant." Another says that "cats are powerfully affected by the odour of them." This root is powerfully attractive; insomuch, that if sixpenny-worth were put into the foot of a stocking, and hung over the mouth of a pit-fall for a few nights, a great number of cats might be taken. About as much of this material as can be held between the finger and thumb, put into a box-trap, will entice a cat to go into it; and if it is placed at the bottom of a 32-sized flower-pot laid on its side, poor puss will put her head through the noose of a snare in order to reach it.

The Carrion Crow and Magpie.—These birds can be entrapped in wears. The most likely places to make them are near pools, spongy places, running water, on edges of rocky hills, and in open fields. In spring, and the beginning of summer, eggs ought to be used as baits, and carrion during the rest of the year. A very good way to take them is to fix a dead cat, rabbit, or an egg in the cleft of a stick, and put it in a pool or pond, or standing water, within 4 inches of the edge, where a trap should be placed, and well covered. If the edge of the pool does not answer well, a narrow turf-bridge 15 inches long should be made, on the extremity of which a bit of flesh or an egg ought to be laid, to entice the bird to walk over the trap. A dead sheep or lamb is excellent bait for carrion crows. This should be placed in an open field, and traps may be set within 6 inches of its belly and eyes. If it is likely that there will be more than one crow at the bait, it is advisable to place traps on the little hillocks that are near it; for when one crow is trapped the others hover above it for a little, and then alight on these hillocks. By these means may be taken all animals that are destructive to game.—*A. Pettigrew, Wrotham Park Gardens.*

FAMILIAR BOTANY.

MORPHOLOGY, No. VI.

(Continued from page 132.)

"Lift up the eye of faith and thou wilt see
The clear blue sky of the untroubled heavens."

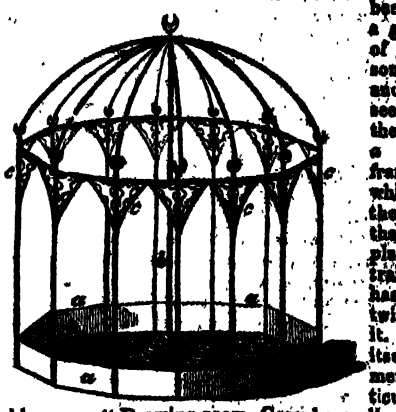
HAVING now cleared away the historical matter which seemed necessary in order to introduce Morphology to your readers, I shall henceforth discontinue all reference to the opinions of individuals, and confine myself to an explanation of what appear, at this day, to be the facts of the case; and for the better doing so I shall begin with the beginning.

Of all the prodigies with which science brings us acquainted, nothing can be compared for interest to the TRANSFORMATIONS OF ELEMENTARY matter. They are so surprising, so difficult to observe, and so entirely unlike what the untaught sense is conscious of, that they are among the last things whose truth reason and evidence succeed in impressing upon the human mind. The Pitt Diamond is valued at the sum of 100,000*l*. This mass of precious adamant is composed of the most valueless material; of nothing better than human breath, solidified by the operation of unknown forces. There is no resemblance whatever between the two substances; fancy cannot paint any two things more entirely dissimilar than human breath and diamond. Nevertheless, they are the same, and beneath the mere action of heat the gem loses its solidity, and is expanded into human breath again. What is, if possible, still more surprising, it was plants which stole from animals the matter of this gem, which, beyond all doubt, is a condensation of charcoal. It, the most brilliant, and most solid substance in creation, is a transformation of one of the most opaque, porous and uninviting materials that we know of. Charcoal itself is but a piece of wood deprived of its water. Here is one great Morphological fact. If you ask why this thing is so, and inquire where the force resides that impressed such properties on matter, the only answer is an appeal to the Most High.

Go into the laboratory of the chemist. He will show you a bottle of air or gas labelled O, and called oxygen; another labelled H, and called hydrogen; a third marked CO_2, and called carbonic acid. These are colourless to be seen, smelled, nor felt. They wholly escape our sensitive organs. You would never believe that the bottles contained anything. But you find that a match burnt brightly in O, sets H on fire, and is extinguished by CO_2. It is, therefore, evident that the bottles do contain something, although the ordinary powers of perception may fail to detect it. Out of similar colourless bottles are plants composed. [illegible] visible, fabric of a [illegible] transparent, untouchable, [illegible] in these bottles, H and O go together and form HO, which is water, the most important and [illegible] of fluid matter; by their union they become visible and touchable; their original qualities are changed; the new compound will neither catch fire like H, nor assist a match to burn like O, but is the sworn enemy of fire in every form. If you doubt this fact the Chemist will separate water for you into its original elements, and H will burn, while O will assist to burn, just as before.

In like manner CO_2 is, by the chemical processes of separation, found to consist of the O already brought on the stage, and C, which signifies charcoal (carbon), so that although soot and all such matters are both opaque and soft, yet they consist in reality of the transparent O and the adamantine matter of the diamond. What can be more strange than this metamorphosis?

But others quite as singular have to follow. The green, the red, the white, the blue of vegetation, the iron trunk of the Oak, the tender mucilage of the Starjelly, the gum, starch, and sugar that nourish us, the many vegetable products that heal our diseases, or cut us off by their poisonous qualities; the soft, the hard, the dry, the moist, fabrics that constitute the solid masses of the vegetable kingdom, are little more than compounds of the H, O, and C already mentioned. For example, 9 parts of H and O, and 12 parts of C go together and form sugar; then if two parts of H and O are added we have gum; a much smaller change produces starch; and the dry unchanging woody texture of a tree only differs from the sugar that is so soft and nutritious, in having a little less of H and O in its composition.



Metamorphoses like these—and there are hundreds of them—give rise to the whole of the infinitely varied products of the Vegetable Kingdom. When the Frenchman is sipping his *eau sucrée*, he is indulging in a feast of charcoal and water; when the laundress views with admiration the magical effects of starch upon her mistress's ruffs and laces, she only does homage to the effects of charcoal and water; the sailor, whose pride is the wooden walls of Old England, is still but a worshipper of charcoal and water; the prince who exchanges his forests for diamonds is a barterer of charcoal for charcoal, and, finally, the whole Vegetable Kingdom is little more than a metamorphosis of charcoal and water in countless masquerading forms.

Such are the elementary changes that science recognises in the matter out of which the tissue of plants is constructed. We shall next see that the many forms of tissue are again metamorphoses of but one simplest type.—*R. E.*

Home Correspondence.

Diseases of Plants.—In treating of the "Diseases of Plants," you say, at p. 99 (Feb. 7), "The medical man divides diseases into *functional* and *organic*, and under the former head places all those diseases in which he cannot detect an alteration in the structure of the diseased organ; but this arises from his want of the power of observing the minute changes of structure on which the diseased function depends. There is no such thing as function independent of structure, and there is no evidence to prove that a function can be deranged whilst the structure is quite perfect." Such a proposition as this should not be allowed to go without some qualification; and it would be well that such an authoritative dictum should not be made to prejudice your readers against one of the most useful maxims, and best rules of guidance, in the practice of their medical advisers. It is true that this useful division of diseases into two great classes is in part conventional, and standing in the stead of a more exact knowledge of the proximate cause, or to speak more popularly, the exact and essential nature of the change in the condition of an organ, which we call disorder or disease. But it is quite as gratuitous, in the present state of our knowledge, to assume, that the action (for that is function) of an organ may not vary, without change of structure; or that the simultaneous action or function of parts (for that constitutes health or disease, as the case may be) may not lose their consentaneousness without such change. Neither proposition, perhaps, is capable of direct and positive proof, and your columns are not the place for a lengthened discussion of the subject; but I will endeavour to show, by a little analogy, that the doctors have some reason on their side. The animal body is composed of many organs, the consistent and harmonious working of which constitutes healthy existence—life; in its best sense—*ease*. If this harmony is disturbed, if any, or all of these organs are unduly worked, or if any one, or some, or all are idle, the healthy current of existence is disturbed, and disease is the consequence. Now, the actions of functions of the several organs depend on certain moving powers, derivable mediately or immediately from the nerves and blood-vessels; and it may happen, and often does happen, that these moving powers are unduly and irregularly supplied, and thence comes derangement of the animal machine, loss of healthy action, and disease; just as an inanimate engine, or a part of it, may be overdone, or underdone, by its moving power, be it steam, or wind, or water, or any other, and a stoppage, or a derangement, of its ordinary or proper function follows. In such a case it is evident the stoppage, or derangement, alike does not depend on any organic change, or structural fault; the moving power, and the object to be set in motion, are exactly balanced, and the machine works badly, or is stopped. Take another analogy (for such illustrations will perhaps be better understood by [illegible] who are not apt to be very [illegible] with the physiological, or pathological [illegible] of their machines), and compare the healthy condition of the animal body to a well-tuned and well-played musical instrument. With the due and appropriate application of the moving power, all is harmony and ease; put the same instrument into the hands of an unskilful artist, let the moving power be unduly distributed, let the various parts be unduly and unartfully animated, and all is discord and disease. To bring the matter more home:—we will suppose a healthy person just about to sit down with a good appetite to his dinner; he is told that his banker, in whose hands he has a large deposit, has stopped payment, and he sends his meat away untasted. Or suppose the happy father of a family, easy in his circumstances, and in the enjoyment of excellent health, having just taken a hearty meal, is told that his eldest son, a college lad, is lying at the point of death, and the first immediate effect is, at the least, a fit of indigestion. In both these cases there is functional derangement without change of structure; reverse the picture to either of these persons, their functional powers and appetites return; or, in other words, the motive power within them operates in its proper channels, and their disease is at an end. Still more to the point:—there are innumerable cases on record where the functions of particular organs have been disturbed for years by what was called sympathy (now more correctly the reflex action of nerves), and have been immediately restored by the removal of the remote excitant cause. In such cases there could not be any structural derangement. Notwithstanding all I have said, I still concede to you, that there is no function independent of organism. I only maintain, that there may be disorder without lesion of parts, or change of structure; and that till we know more of the proximate changes of the vital actions (vital Chemistry, I might have said) we have reason to abide by a distinction as philosophical as it is convenient—so convenient, that I bet my best Melon, of the forthcoming summer, to "L. E.'s" best bunch of Grapes (the good English method of settling a dispute), that he will by-and-by, when he treats of the diseases of plants, produced by too much or too little nutriment, too much or too little warmth, and so forth, use the distinctions, and perhaps the phrases now in discussion. In the foregoing illustrations of my position, I have not overlooked the objection which will probably occur to the able writer of your "article," that a change may take place and does take place in the vascular system, and the distribution of blood in the disturbed organs; and this he will say is tantamount to structural change. I have provided against this by admitting the agency of that fluid as a motive power. More may be said to meet this objection; but your readers will probably think there is enough for the present.—*M. D.* [We must still maintain that our position is correct. "M.D.," in his own instances, shows clearly that there must be derangement of structure to produce functional disorder. The *convenience* of the term functional disease in medicine we admit, but we deny its *correctness*. We shall endeavour in all cases to point out the structural change on which the decayed functions of plants depend.—*L. E.*]

Ward's Cases.—The following is a drawing of a "Ward's case" of my own designing and making. It has been filled with a great variety of plants for some time past, and they all seem to enjoy their position. *a a a* is the frame or case which contains the soil in which the plants are placed; the central pillar, *b*, has a creeper twining round it. The house itself is ornamental, and particularly suitable as a "Drawing-room Greenhouse." It seems to require very little care except occasionally picking off decayed leaves. The shape is exceedingly light and simple, and it can be made even more so by the omission of the arches and "tracery" marked *c*.—*J. L. Knox, Swiston Gardenes.*

The Fastolff Raspberry.—I obtained in 1842 some canes of the large sort of Raspberry mentioned by "Fair Play" as growing at Filby, and at the same time canes of the Fastolff from Messrs. Youell and Co.; the latter proved far superior both in size and flavour of fruit, the canes growing to the height of nine feet and literally covered with fruit.—*Justice, Liverpool.* [We have this correspondent's name.]

Cucumbers.—For two years past I have entirely discarded the old method of growing Cucumbers on dung hot-beds, or of allowing them to grow on the surface of the soil at any time. I find that by training them to trellises I have not half the trouble with them that is required by the old plan, and that the plants continue much longer in bearing when so treated. I have had plants in this way continue in a bearing state and in perfect health for upwards of twelve months, and it is very seldom we are without Cucumbers from all the year round. We have at this place a range of pits [illegible] a hundred feet in length and nine feet wide inside, heated with two

rows of bricks on edge along the front and both ends; the water or return-pipe lies in a trough made of bricks and Roman cement; this can be filled with water as an ordinary to cover the pipe, that it may raise a constant and powerful steam in the pit when required. Besides Pine-apples, in this pit I grow Melons, Cucumbers, and various other things. Instead of brick partitions I have movable wooden ones, which I find very convenient. By this means I can easily enlarge or reduce the size of each compartment to suit exactly the purpose it may be wanted for. Suppose that in next autumn I shall have fruited off a number of Pines, and consequently have three or four lights to spare, I shall begin to prepare for a winter crop of Cucumbers. After throwing out all the tan, and fixing in a partition of boards, I next build a temporary wall of loose bricks lengthwise, about four feet from the front wall, and fill up the space with tan for bottom-heat. When the heat is risen to the proper degree for putting in the plants, the soil is put on in little hills at first, and the trellis is fixed in its place, in which is left an open space at the back, in one of the corners, about two feet square, for the purpose of going in to regulate the plants. This is very easily accomplished by pushing down the light and having a short ladder to step upon; the laps in the glass are puttied perfectly close, and for at least four months in winter no air whatever is admitted, and the plants receive very little water,—say once in a month at most,—and then only a small quantity is given them. In pruning up the centre of each light I generally take only a single shoot, which pushes out its bearing laterals throughout its whole length, and this covers the whole surface of the trellis under the light. Should any accident happen to the main shoot, a lateral brought into its place will soon fill up the vacancy. With respect to the sorts most worthy of cultivation, I have tried a good many of the most famed varieties for three years past, and I find they differ widely, both with regard to bearing and hardiness. The true Sion Cucumber is the kind that I prefer before all others for general cultivation; it is a hardy and prolific bearer, and answers either in winter or in summer for pot-culture or for planting out in beds. Of the long kinds the best I have met with is one that was sold in London two years since, under the name of the Superb White Spine; it is hardy, and a good bearer. I had three lights of it last year, which kept in bearing for 12 months, and would have borne longer if they had been allowed. It frequently grows from 22 to 26 inches long, and is a very handsome-shaped fruit. From one plant of this growing in a box standing on the footpath in a corner of the Pine-stove, I have cut, since the middle of January, seven brace, averaging 18 inches in length each. The black-spined sorts appear to require a stronger heat, and are of a more rambling habit than those that are white-spined; but I have just now in bearing three lights of Latter's Victory of England, which seems to be a very hardy sort, as well as a handsome and prolific bearer; it is the best black-spined Cucumber I have yet met with. —*Robert Reid, Noble Thorpe.*

Inscriptions.—In order to clear a stone slab of Lichens, place the stone face downwards on the ground, if convenient; but if that cannot be done, cover it with loam or soil—the richer the better. If the stone should form part of a wall, this may, nevertheless, be done by fixing a board a short distance from it, and filling up the space with soil. In Scotland, grave-stones may be frequently seen lying on the ground, face downwards, for the purpose of destroying Lichens and rendering the inscriptions legible.—*Y. G. H.*

Yeast.—We have received three recipes for making yeast, from different correspondents. One informs us that the following never fails to make light good bread:—Mash about two quarts of malt in a gallon of boiling water, and let it stand about two hours, then skim it off into another small tub, and when it is sufficiently cool, add a table-spoonful of yeast, which will produce a sufficient quantity for a large baking. Repeat this whenever you want a fresh supply, always keeping a little of the former yeast to make the next work; the process is the same as brewing, only without adding Hops, or boiling the wort. If the weather is very cold it may require to be put by the kitchen fire to make it work. What will fall to the bottom of the tub, besides that which rises to the top.——Another states that eight gallons of excellent yeast may be made as follows:—Take ten gallons of water, and half a pound of Hops, boil them for two hours, then strain the liquor into a tub, and stir in half a peck of ground malt, mix them well together and stir occasionally; let it stand until blood-warm, then take one gallon of yeast, from the brewer at first, and afterwards from the residue of your own stock, with two pounds of flour, mix all together, and let it work eight hours, then stir it up, and strain into a barrel, and keep it well corked. The yeast will be about eight gallons, which has an appearance between that of thick beer and thin yeast. The method of using this yeast for the manufacture of 35 stone of bread is as follows:—Boil one and a half peck of Potatoes, mash them well and strain them, add about one and a half gallon of soft water, mix them well together, then one pound of the above patent yeast, with two pounds of flour, stir up well, and cover down for five hours prior to setting sponge, which will be ready in seven or eight hours, according to the weather; great attention must be paid in making the sponge at the first or second rail, in order to get the bread sweet. The dough must not be allowed to lie longer than an hour in hot weather, but put into the oven as soon as possible. This will be found to produce very excellent yeast that can be made, if properly used. This receipt is on a large scale and will, of course, have to be proportionably divided for domestic use. If a smaller quantity be made, viz., a gallon or two, it will fill a stone bottle, quite corked, and put in a cool place, keep good for a long time.——A third communication says:—Boil one ounce of Hops in four quarts of water until the Hops fall to the bottom of the pan, strain it, and when milk-warm, add six ounces of flour and five of sugar; set the mixture by the fire, stirring it frequently; in 48 hours add four pounds of potatoes, boiled and bruised fine; next day bottle the yeast—it will keep a month. One-fourth of yeast, and three of warm water, is the proportion for baking.*** [We have tried this, and find it a good substitute for yeast. A fourth communication on this subject very nearly agrees with the last.]

What is the best Temperature for the Pine-Apple?—We are always best answered if the reply to our queries can be obtained from Nature; and the reply, therefore, to the above query shall be from observations made at Calcutta. In the vicinity of that city, the yellow-fleshed Pine-apples are high-flavoured, and commonly weigh between 5 and 6 lbs.; and Mr. Speede, in his "Indian Hand-Book of Gardening," says (p. 183) that, by a system of very ordinary cultivation, his brother grew them weighing 7½ lbs. This was, of course, when the plants were exposed to a climate of which the following Table shows the monthly averages of temperature taken at the hottest and coldest periods of the 24 hours. Now, although Pine-apples may be obtained nearly all the year at Calcutta, yet their period of greatest perfection is from April to September. This may be termed their ripening or stove period; and it will be found, upon referring to this Table, that the average maximum temperature of that period is above 91°, and the average minimum more than 79°:

	J.	F.	M.	A.	M.	J.	Jy	A.	S.	O.	N.	D.
Max. Temp.	84.5	90	90.8	97.	95.	91.5	88.	87.	90.	91.	85 5	81.5
Min. Temp.	60.	63.	71.	77.5	78.5	81.	80.	40.	80.	75.	64.	57.

I may just observe that the above are average temperatures, and that the Pine-apple in Bengal often has to endure such widely-differing temperatures as 129° and 53°. From these facts I conclude, that if in England the temperatures each month never ranged higher in the Pinery than the minimums in the above Table, they would not be too high in proportion to the diminished light of our latitude.—*George W. Johnson.*

Larch and other Resinous Trees.—In a late Number are some observations by "C. Wren," on an article of mine, p. 61, on the propriety of felling Larch for durability in the early part of summer. The words, "June is the best time to fell resinous trees for durability," require explanation. What I intended to say was this: "My friend—an experienced person—says they should be felled just when the sap begins to be fluid, in spring before the first buds and leaves are expanded, as the resinous fluid is more regularly dispersed in the wood" (perhaps by being more miscible, and filling up the pores—at least he said the timber was better from that circumstance.) This brings the time I intended to state for felling such trees to the period "C. W. H." proposes, viz., in March. I then inquired if such were the fact, and could it be corroborated by other experienced persons? As the sap or resinous fluid remains in Larches in a dormant state all the winter, viz., in the state in which it was deposited at the end of the previous autumn, it cannot have undergone much change, if any, before the buds and leaves have expanded; therefore there can be no doubt but early in spring is the best season for felling such trees, but whether just before or after the sap begins to be in motion, requires to be proved by accurate experiment—I am inclined to think after. The best time to prune resinous trees, to prevent bleeding, is soon after the sap is fixed, late in autumn or early in winter, or else after the first buds and leaves have expanded in spring, but by no means when the sap first begins to flow in spring.—*W. Billington.*

Preservation of Wood.—In a late *Chronicle*, "A Subscriber" asks for information about Burnett's Antiseptic Solution. This is the chloride of zinc, patented by Sir William Burnett in 1838, and which has been very successfully tried at the Woolwich Dock Yards, and is now becoming adopted in the navy. It has been found superior to Kyan's Patent Solution, the chloride of mercury. The solution of the chloride of zinc contains one pound of the chloride to five gallons of water. Another simple process for preserving wood and other substances appears to be that of Mr. John Bethell. This consists in the application of creosote, along with coal-tar, or other bituminous matter. The wood is thoroughly saturated to the centre of the log with great rapidity. A load of Fir timber will absorb as much as forty gallons, the close-grained woods less. A cubic foot of Beech usually weighs 8lbs. heavier after it has been prepared by this plan than before. The price of the creosote is 3*d.* per gallon. In some places—Liverpool, for instance—it may be had for 2½*d.* Preserved timber, by Bethell's process, is supplied to the railways at 15*s.* a load beyond the price of common timber. The use of creosote is strongly recommended by Sir John Barrow, in his "Life of Lord Anson." He states that Kyan's Patent (corrosive sublimate) does not prevent decay, neither does it prevent the Teredo navalis from penetrating the timber, as has been proved at the Dock Yards. Wood treated with creosote becomes nearly waterproof, and is not touched by the T. navalis; it requires no painting, but after exposure of some days it loses every unpleasant smell.—*J.*

Transportation of Bees.—In answer to "C. W.'s" inquiry, I beg to inform him that I secured my Bees in their boxes, by screwing each box down firmly to its box—covering the entrances with perforated wire. The boxes were then laid upon the bottom of a large deal case, at such a distance from each other and from the sides of the case, as to allow straw mats to be pushed in tightly between and around them, leaving the entrances free. The case was then laid on the floor of one of those fly-vans which are constructed with double springs, for the conveyance of musical instruments. Thus accommodated, I accompanied the Bees on their journey, travelling with them about 90 miles, and occupying nearly three days in the transit. On examining them at the end of their journey not a Bee nor a comb appeared to have sustained the slightest injury. After placing them in their new locality I gave them their liberty, when they issued forth most vigorously and joyously, and soon felt themselves at home.—*Edw. Bevan, Esgair Evan, Montgomeryshire.*

The Polyanthus.—I have been much pleased with "W.'s" remarks upon the Polyanthus, and agree with what is advanced regarding the necessity of paying more attention to the raising of new varieties; but this is not so easy a matter as may be imagined. There is so great a similarity in all the seedlings that are yearly raised, it rarely happens that a distinct variety can be obtained. It is said that attention has not been paid to collect seed from first-rate varieties; but I can assert that seedlings have been raised from one which is considered a leading one; viz., Hufton's Earl Grey, *alias* Clegg's Lord John Russell, that cannot be distinguished from the original; although only Pearson's Alexander, Buck's George IV., Nicholson's Bang Europe, Collier's Princess Royal, as well as some others equally select, were grown in the garden. Pearson's Alexander generally produces seedlings so much similar to the parent, that many now sold as Pearson's Alexander are nothing but seedlings from it. The great difficulty in seedlings is getting them distinct with respect to marking and character; and the question is, how is this to be remedied? for seed sown from first-rate sorts only has been unsuccessful, and some of the more recent new varieties have been accidentally raised by persons who grow only a few plants, and those not leading ones. Cheshire Favourite was raised by an individual who professes only to be a Gooseberry grower, and has only a straggling plant or two. There is ample room for improvement, and the only way of attaining that object is perseverance, and, occasionally, something may turn out different, which will amply repay the florist for his trouble and exertions. The cultivation of seedlings, if not attended with success, will be a source of enjoyment to the fancier, as seedlings generally are more vigorous, and bloom more freely than such as have been a long time in cultivation; and although they may not be quite equal to the parent, yet they may be planted in the borders, as they are not so tender as those that have been nursed long. With respect to the management of Polyanthuses, *I do not think they are so difficult to manage* as is represented. I am afraid the reason why they do not succeed in the south is, that proper care is not taken of them. Loudon, in his "Encyclopædia of Gardening," says, "they are very hardy, and will stand the wettest and most severe weather;" but the only varieties that will stand all weathers, are Buck's George IV., Faulkner's Black Prince, and Boardman's Victoria; the two last are not considered stage varieties at the present time. Probably, in mild winters, a collection may be wintered on a warm border; but in the north they are not risked; all are framed. I am not an advocate for their being grown in pots, although when they are raised in that way for exhibition, they can be placed in any situation, and either hastened or retarded, as required; and when the bloom is over, if is easy to have a border prepared twelve inches deep, of the following compost:—

1 barrowful of rotted cow-dung.
1 „ horse-dung (droppings are generally used.)
1 „ maiden-earth.
1 „ peat earth.

all which should be mixed up and worked for twelve months previous to using, so that it may be rendered perfectly sweet and pure. Put the plants in this, not plunging the pots, without displacing much soil. I have witnessed the superiority of the mode of growing plants in a border, and shall, until I find occasion to alter, continue that system, although the potting system is principally adopted here. The border in which I grow my plants, is bounded by a double hedge—the outer one is of Thorns, and the inner one of Beech-trees; it is again subdivided by Beech-trees every five yards, which prevents the sun's rays from acting too powerfully upon the plants, and causing them to flag; it also keeps them cool. The border has only the sun shining upon it until eleven o'clock in the morning, and the fence screens them from the mid-day heat. I put down a frame of wood eighteen inches high at the back, and nine inches at the front, and fill in the compost, which is deep enough to bloom the plants in. Glass-lights four feet by three feet are kept over them from October to the end of April, in order to protect them from all severe weather, taking especial care to take off the lights every mild day, and to give them as much air as possible during that time; but, above all things, I take care to protect them from receiving much rain from October until February, as they do not like much moisture; besides, when they are too moist, severe frosts have much greater effect upon them. Emerson says they require the same treatment as Auriculas, which coincides with my practice. In order to give them air during wet days, I have a curved flat iron, about 18 inches long, 1 inch broad, and about ⅛ of an inch thick, with 4 holes like a keyhole placed at equal distances, and fastened by a staple to the frame, being furnished with a pin having a square shank and head sufficient to go through the wide part at the top, which falls down and keeps the light perfectly fast in windy weather, and it can be elevated or lowered according to circumstances, and this mode mildew is prevented. I have taken up plants with roots from 12 to 18 inches long, and

look much healthier than when they are grown in pots. I have lost during this pleasant winter six plants in pots for one growing in the border, although the number of plants in the latter is almost six times that of the former. There is another advantage also gained, viz., the plants being more vigorous, and also much more moist, they are not so liable to be attacked in a dry summer by red spider. I have no doubt that if the above plan is followed out, the difficulty of growing Polyanthuses near London will be obviated, and this favourite flower will once more adorn the gardens of the metropolis.—*John Slater, Cheetham Hill, Manchester.*

Vineyards.—When we consider the trifling expense of cultivation, and the valueless soil in which the Vine will succeed—(it will ripen much better, and be finer flavoured, on a hot, dry, poor soil than on one rich and moist)—it is certainly very strange that this branch of our domestic and rural economy should have been neglected these last 150 years. About this time back immense quantities of wine used to be made for home consumption, and by private families; for instance, at Hatfield, Painshill, Arundle Castle, Hammersmith and many other places. On the warm gravels of Hertfordshire, the sands of Beds and the chalky hills around Brighton Dover, Deal, &c., which are exactly the localities and soils chosen in Normandy where the Vineyards are situated, it may be safely asserted that no other crop is so profitable on this description of soils The Fruit in this country, in the worst of seasons, when not sufficiently ripe to be eaten, will make wine fit for pies, tarts, &c. The following sorts are well adapted for this country—White Muscadine, Burgundy, July, Verdelho, Turner's Hardy, Esperione, and Black Cluster, and never fail of a crop. A plantation may be made with cuttings about 18 inches in length, of well-ripened wood; layers the second year, and cuttings the third year, come into bearing, and continue prolific for ages. Herewith I send you directions for making a plantation, which is the result of experience. Plant your Vines 4 feet apart every way; dig holes, and in each put a very little rotten manure; place your plant in the centre, and firmly press the soil round the plant; cut layers down the first year, cuttings the third year, leaving about six eyes only to break from; this to be performed in February; select three of the strongest shoots to remain to each plant; always retain last year's wood for bearing; the summer pruning consists in stopping each shoot when 4 feet high; at which height they must remain, and cutting away all laterals; the three shoots to be tied loosely, as Raspberry canes, to admit the light, &c; the ground to be kept clean by hoeing only. Each plant will produce, on an average, a dozen bunches; the lowest produce from one acre of poor ground, worth 10*s.*, as follows.—3,500 plants, 42,000 bunches of Grapes at one farthing per bunch, 43*l.* add.—*Vitis.* [*Good* wine cannot be made in England; and *bad* wine may be bought cheaper than it can be made.]

Pruning Forest trees.—In the *Chronicle* for Jan 13, Mr. Thackeray describes his practice on this subject That gentleman is right in "planting those trees the soil most loves," but the subject that I wish to advance a few remarks upon is, whether curtailing, mutilating, or lessening the head of a tree has a tendency to increase the bulk of its stem—that is, facilitate its growth into timber, which is what is required? Dr. T says, speaking of plantations made in 1814, "They have been pruned and thinned annually since that period, by taking off from 3 to 5 branches, as before described; and the result has been, that the sap which the cut branches would have exhausted has given vigour and increased strength to the trunk, as is evident from the healthy appearance of the trees, as well as their augmented size." This is founded on the supposition which I have endeavoured to expose from the first starting of the subject in your columns, viz., that what is taken from the head must necessarily be laid on the stem, forgetting the true principle of increase—namely, reciprocal action between roots and branches. The fallacy lies in supposing that the action of the roots will continue the same, whether the head is curtailed or left entire. I by no means disapprove of a little knife-work on young plantations, and highly approve of Dr. T.'s attention to his. Will Dr. T. allow me to ask, how long does he propose his system should be continued—or at what age or size of the trees would he alter or discontinue his practice? I live among many magnificent trees, and see, in abundance of instances around me, the evils resulting from bad management, or no management at all; but I never yet saw a magnificent stem that had not a proportionably large head. "Cut wood and have wood," which Dr. T. has adopted as a motto, has also been assented to by Mr. Hammerton; but its application as a maxim requires some degree of discretion, and Mr. Hammerton's mode of carrying out the maxim is what I should be disposed to approve of. I trust, before another pruning season arrives, those who now so strongly advocate pruning may be induced to consider the true principle of increase, viz., reciprocity between roots and branches; they will then be cautious of interrupting that principle by any system of pruning whatever, and will perceive the fallacy of indulging the idea, that what is taken from the head must necessarily be added to the stem.—*Querens.*

Wild Mistletoe.—In reference to the article on the subject of this parasite, at p. 95, I observe that your correspondent quotes the opinion of Sir John Colbatch. I presume this must be the same John Colbatch who wrote a treatise on "the Mistletoe of the Oak," London, 1719. He was a Member of the College of Physicians, and found the Mistletoe efficacious against the epilepsy, chorea Sancti Viti, and other diseases of the nervous system, giving half a drachm of the powder every three or four hours. The book contains full directions for collecting and preparing the plant, which, it appears, was then imported, he says, gathered from trees other than the Oak. Does not this tend to prove that the Oak 150 years ago was the principal support of the plant? An example on a large scale of the Mistletoe's affection for the Lime (Tilia), is to be found in Kent, at Sundridge Park, the seat of Lord De Lisle, where in the winter season the very lofty avenue of that tree has, at a little distance, the appearance of a rookery, from the undisturbed and luxuriant growth of the parasite—attributable, no doubt, to its being beyond the reach of Christmas depredators. I have some recollection of seeing it on the Elm close to the same locality, but for this I cannot at the present moment vouch.—*Anonymous.*

Mixture to Heal Wounds on Trees.—I have not found any mixture so good for this purpose as bird-lime; of course the wound of a tree must be dry when it is applied, and therefore it is requisite that a bough or limb should be cut off, one, two, or three days previous to its application, and that the wound should be pared and in readiness. I have in June cut off a limb of an Oak, four or five inches in diameter. I first saw half through the limb at about six inches from the trunk, with the saw teeth upwards. I then saw an inch or two higher up the limb downwards, until the limb drops. The stump is then cut off close to the trunk, taking care not to tear the bark, and the wound is pared clean with a draw-knife, or paring-chisel. If the weather is fine and dry the bird-lime will adhere on the second day. The bird lime is in a gallipot, and this is placed in water at the heat of 110°, the lime is spread thinly all over the wound, and just a little beyond its edge. This material dries of not a bad colour; but if desired to be very nice indeed, it may be powdered over with a mixture of powdered sumac, indigo, ivory-black, flour dried, old tanners' bark, of which or of some of them a mixture may be made to imitate the colour of the bark of any tree. I imagine pitch mixtures could not be applied unless the wound was in a dry state.—*J. C. X., Bermondsey.*

Winter-felled Oak.—Mr. Billington, in his article on this subject, in a late *Chronicle*, says that "The numerals are thus 1035, old-fashioned figures," &c If the figures are Roman numerals, the date may be correct; but if Arabic there must be some mistake, for the Arabic numerals were not used in this country till the fourteenth century. Of the superiority of winter-cut Oak, all carpenters are pretty well agreed; it seems to be an inveterate opinion, as far, at least, as the "sap Oak" timber is concerned. "Heart Oak" is so durable, cut when it may be, that the eight centuries, supposed by Mr. B for the duration of his Oak beam, are very likely. Two summers ago I met in Normandy with a well-carved inscription, in old French, thus [illegible&hout] on an Oak beam that had been a chimney lintel There can be little doubt that, if preserved from wet, it would last five centuries more The soft or sap part of Oak timber is soon eaten up by the worms, unless winter-cut. I have seen timber taken out of old buildings with the bark still on it with some worm holes in it, but I believe the prejudice in favour of such timber is founded in *fact* and experience. I have lost an authority, which some of your readers will probably help me to again, in regard to the fact, that the gates of Constantinople, which were put up by Constantine, were still hanging when it was captured by the Turks. I thought it was in a foot-note of "Gibbon," but I do not find it there But these, like the gates of Somnauth, I believe were of Cedar, or some such Oriental timber.—*P. P.*

New Heating Apparatus.—The invention described under this title at page 806 of the *Gardeners' Chronicle* for 1843, and said to be constructed on an entirely new principle, will be found to be the same as the hot-air stove known as Boyce's patent. Their mode of action is precisely similar—a current of air being admitted into a kind of chamber surrounding the furnace—which after being heated by the thick iron plate of which the furnace is composed, passes off in pipes communicating with the chamber and opening into the apartments intended to be warmed. In Boyce's patent the furnace is fixed in such a manner as to preclude the possibility of any danger arising from the fire, or from the pipes becoming overheated The latter in fact never can be the case, as the pipes are merely conductors of the heated air, and have no connection with the open fireplace. They are generally made of thin copper, and are about four or five inches diameter. The circulation is regulated by ventilators which admit of its being increased or diminished at pleasure For warming large buildings, I have reason to know that this kind of stove answers the purpose most completely; but I very much question whether it will be found so well adapted for Horticultural purposes, as the heat obtained from it is always dry compared with that derived from the circulation of hot water on the tank or open-gutter system.—*W. B. Booth.*

Budding and Inarching.—In your Paper of the 27th ult., there is an article on this subject, signed "W. G." If I understand the writer correctly, he cuts off a growing bud or shoot, when the leaves do not exceed two inches in diameter, and inserts it in the usual method of budding. Will "W. G." state how much of the bark he cuts with the young shoot?—*A Subscriber, Maidstone.*

Roses.—Mr. Pettigrew has now presented you with his animadversions on the "Honey Bee," and his remarks on Bee culture in general, and brought both to a conclusion. But I feel by no means disposed to flatter at any length upon a reply to him. It would be almost tantamount to undertaking the task of publishing a third edition of the "Honey Bee," which I must be impelled to by some stronger inducement than Mr. Pettigrew has held out to me. To my readers and well-wishers of this system of management, accustomed to their work, I might perhaps in duty, their kind confidence and the statements it contains remain unanswered by anything advanced by Mr. Pettigrew. Any inquiries, however, from whatever quarter, as to the rationale of this system, shall be attempted to be fully replied to, as they always have been. This Mr. Pettigrew, as a constant reader of the *Gardeners' Chronicle*, must be aware of.—*Edward Bevan, Regent Street, Monmouthshire.*

Societies.

HORTICULTURAL SOCIETY.

March 5.—R. W. Barchard, Esq., in the chair. Col. W. Mason, J. Dixon, G. H. Hooper, J. Bateman, and A. G. Fullerton, Esqrs., were elected Fellows. From S. Rucker, Esq., were two exceedingly handsome large-flowered varieties of the Lycaste Skinneri, differing in colour, the one being paler, with a more distinctly marked lip than the other, which was of a deeper purple. Along with these was Phalænopsis amabilis, a plant of great beauty, having a fine branching raceme of large showy white blossoms; also a specimen of Cyttochilum maculatum, having two pretty spikes of brown and white blossoms; and a plant of Cypripedium barbatum, which considerably resembles venustum. From the same collection was likewise the scarce Galeandra Devoniana, and a cut spike of Coryanthes maculata, curious, on account of having its lip gathered up into a kind of bucket, which serves in the economy of the plant to hold a sweet fluid, which slowly drops into it from two processes or secreting glands that are situated immediately above it—a large silver medal was awarded to Mr. Rucker for this collection.—Mr. Robertson, gr. to Mrs. Lawrence, sent a well-grown plant of Æschynanthus maculatus with dark fleshy leaves, among which its numerous clusters of gorgeous scarlet blossoms produced a pretty effect. Also plants of the pretty Schomburgkia undulata and S. crispa, having tall flower stems bearing rich heads of showy blossoms. From the same collection was likewise a pretty plant of Camarotis purpurea, growing in a basket, and a well-grown specimen of Styphelia tubiflora, a greenhouse plant of a gay graceful appearance—a Knightian medal was awarded for the Schomburgkias, Camarotis, and Styphelia.—From Messrs. Rollisson, of Tooting, were beautiful plants of Dendrobium densiflorum and D. Cambridgeanum, the latter with handsome racemes of bright orange blossoms, having a pretty dark velvety spot on the labellum. In the same collection was likewise Phalænopsis amabilis in good condition; also Coelogyne cristata, a scarce plant, having pretty fragrant blossoms of pure white, except the lip which, in the centre, is covered with bright yellow fringes; also a beautiful large-flowered variety of Oncidium papilio, much superior to the old one, both in point of size and colour. Messrs. Rollisson likewise sent a variety of Cattleya Mossiæ, a Maxillaria from Guatemala, and a new species of Miltonia from Brazil, having handsome brown and white blossoms; a Knightian medal was awarded for these.—Mr. Henderson, gr. to F. Cox, Esq., of Stockwell, exhibited Stanhopea quadricornis, having a fine spike of flowers; Zygopetalum rostratum, Oncidium papilio, and Dendrobium Pierardi, on a block, in good condition.—From Messrs. Veitch and Son, of Exeter, was Lycaste Skinneri, and Barkeosia squamata, with red star-like flowers, and a small hard dry foliage, that was lately introduced by Mr. Veitch's collector; a certificate was awarded for it.—From Mr. Jackson, of Kingston, was a cut specimen of Inga pulcherrima, a pretty stove plant, having charming tassels of bloom, which are formed by the long crimson filaments. C. B. Warner, Esq., sent a collection of cut flowers, among which were Dendrobium densiflorum, Camarotis purpurea, a Bletia, &c.—Mrs. Marryatt sent a cut flower of Schomburgkia marginata which, although not so showy as others of this genus, is nevertheless pretty.—Mr. Glendinning, of Chiswick Nursery, sent a beautiful plant of Eriostemon buxifolius, of which he writes as follows:—"It is one of the prettiest plants we have, and may be forced into flower at any period during the winter months. Its fine dark green foliage, and neat habit, combined with its abundant snow-white, sweet-scented blossoms, render it an object of much interest. It will stand a good deal of forcing without the least injury, and remain in blossom for a considerable period. It is, therefore, a plant not only desirable for summer exhibition; but more especially for decorating the conservatory or drawing-room in winter. Cut sprigs of it are very useful in making bouquets." Mr. Glendinning states that this plant, which is now in good health and covered with bloom, was of small size, growing in a small pot about six months ago, and in bad health; but that the large shift and a higher temperature had brought it to its present healthy and luxuriant state; a Banksian medal was awarded for this.—From Mr. Hamp, gr. to J. Thorne, Esq., was a bushy plant of Epacris nivalis, a large specimen of Phaius Tankervillii, and a small plant of Franciscea Hopeana, along with Erica transparens, which was in good condition.—Sir C. Monck, Bart., sent specimens of Forbidden Fruit for exhibition. From the same gentleman was also the following communication respecting the destruction of brown scale on Orange-trees:—"I ascertained by experiment, that an infusion of Camomile would serve to clear Orange-trees of their most baneful pest, the brown scale. I am confirmed in the opinion; my trees are cleared, and have proportionably recovered their health." The fruit exhibited were in good condition, and were stated to have been gathered from a small tree which had had no more accommodation than was afforded by a shady Winery in summer, and the same Winery in winter.—From Mr. Dunsford, gr. to W. Bennett, Esq., was a house of

Cucumbers, each 18½ inches long, that had been cut from a dung-pit six weeks after putting out.—Mr. Apted, gr. to C. L. Stephens, Esq., sent two brace of Cucumbers, the longest measuring 19 inches in length; they were grown in a pit that is heated by Rann's system. For these a certificate was granted.—Mr. Doran, gr. to T. Hanes, Esq., sent three specimens of Cucumbers.—From J. Biddulph, Esq., were six specimens of Apples, in good condition.—From the garden of the Society were Chysis bractescens, Epidendrum Stamfordianum, a charming fragrant species, sent to the Society from Guatemala, by Mr. Hartweg; also E. cinnabarinum, Rhyncha, ignea, Acacia vernicifiua, and another species, along with Arctostaphylos pungens, which is a neat little half-hardy evergreen shrub, that was introduced from Mexico, by Mr. Hartweg.—Cuttings were distributed of Knight's Monarch Pear, stated to be hardy and a good bearer, succeeding best as a standard, and bearing rich and melting fruit which keep well until January: the Dunmore Pear, also raised by Mr. Knight; it is perfectly hardy, and the fruit attains a large size, on a standard partaking of the flavour of the Brown Beurré, when the latter is perfectly ripened. There were also cuttings of the Blue Perdrigon Plum, sometimes known by the name of Brignole Violet; it is one of the varieties which furnish the Brignole Prunes; the fruit is of a purple colour, very rich, and comes into use soon after the Green Gage. Likewise the Perdrigon Violet Hâtif, which, in some respects, resembles the former, but is quite distinct, ripening much earlier; the flesh is so very rich, that, instead of decaying rapidly when ripe, the fruit will hang and become shrivelled on the tree.

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

GENISTA VIRGATA. Twiggy Broom. (*Hardy Shrub.*) Leguminosæ. Monadelphia Decandria.—Mr. Young, Nurseryman, Milford, states that with him this is a very handsome compact shrub, which resisted the hard winter of 1836-7. It was raised from the seeds sent by Mr. Webb from Madeira in 1838, was turned out in 1839 into the open border, and is now a very woody shrub. It is deserving a place in all shrubberies. In the garden of the Horticultural Society it grows about four feet high, and is capable of enduring the ordinary winters round London, if placed in a dry situation, and planted in a loamy soil. It is increased by seeds, or by cuttings of the young wood after midsummer. The cuttings should be placed in a shady situation, in light sandy soil, and covered with a hand-glass. It if were treely in May and June, and forms a loose rather spreading bush, rather thin of foliage. In the nurseries it is generally known by the name of Spartium virgatum. In such wild and cultivated specimens as we have had the opportunity of examining, the leaves were uniformly simple; in Mr. Young's specimen, however, the lowest on each twig, those, in fact, from whose axil the twigs proceeded, were trifoliolate. This is interesting, as showing an occasional passage to the 3-leaved species, even among those whose foliage is most decidedly simple.—*Botanical Register.*

LUXEMBURGIA CILIOSA. Fringe-leaved Luxemburgia. (*Stove Shrub.*) Violaceæ. Monadelphia Polyandria.—This fine plant forms a very elegant shrub, from two to four feet high; but it is said to attain a height of eight to twelve feet in Brazil, where it also bears branches. "It was first detected," says Sir W. J. Hooker, "by Martius, in the Diamond district, province of Minas Geraes; and subsequently in the year 1841, by Mr. Gardner, in moist, peaty soil, in open places, growing with species of Andromeda, on the Organ Mountains, at an elevation of 3000 feet above the level of the sea. It has been in British collections about eighteen months or two years, and flowered in several places during the season of 1841. We saw beautiful specimens from the Royal Botanic Gardens of Kew; from Messrs. Lucombe, Pince, and Co., of Exeter; at the nursery of Mr. Knight, King's-road, Chelsea; and in other large nurseries. It is through Mr. Gardner that the stock now in England appears to have been obtained. No plant can be more regular, neat, and pleasing in its mode of growth. There is a very peculiar symmetry, cleanness, and healthiness about it, which seem to attend it in all conditions, and give it a most ornamental appearance. It grows perfectly erect, with a clear stem, and, as we have seen it, to about a foot or eighteen inches in height, without at present having borne any branches. It is well clothed with leaves, from about four or six inches above the soil, and these leaves are long, narrow, very elegant, of the purest green, and delicately cut along the edges into hair-like teeth, which are remarkable for their extreme uniformity. From the top of the stem an upright spike of flowers issues, forming a sort of cone. The flowers are numerous, well disposed, large, and of a clear lively yellow. They last a considerable time, and are produced abundantly on plants not more than a foot high. The species requires a stove temperature, and a moist atmosphere, with a rather enriched loamy soil. It would most probably be benefited by a gentle bottom-heat. Were it once to branch in this country, as it may possibly be induced to do by cutting off its summit, its spikes of flowers, proceeding from the extremity of every shoot, will render it one of the very best of our stove plants.—*Paxton's Magazine of Botany.*

Miscellaneous.

A Textile Plant from China.—M. Stanislas Julien has given to the Museum of Natural History (at Paris), the seeds of a Textile plant, which M. l'Abbé Volain, one of the directors of foreign missions, obtained from China. This plant, which they call Ke-hoang-kin, Louho, and Khi-thai, is met with everywhere, but particularly in the provinces of Tche-Kiang and Tiang-Nan. M. Julien has taken its description, the details connected with its cultivation, and the preparation of the clothing that is made from it, from the "Encyclopædia of Chinese Agriculture." The seeds germinated in the Garden of Plants, and its botanical characters, will soon be ascertained. In the meantime, M. de Jussieu thinks that the plant is a Kidney-Bean, near Dolichos, and particularly D. bulbosus.—*Mag. Hort., Nov.* 1841.—T.

Pelargonium Leaves a Cure for Wounds.—The leaves of the Pelargonium are, as everybody knows, strongly scented; some smell of Rose, others of Lemons, Apples, &c.; there are also other sorts, which, when bruised, have a nauseous and rather disagreeable odour. All the species and varieties of this genus contain a large quantity of essential oil, which is usually fatty; there are several sorts which are cultivated in the open air in the south of France, and particularly at Nice, for the purpose of extracting the oil, which is sold to the perfumers. The leaves of all Pelargoniums have also the property of healing cuts, places where the skin has been grazed off, and other sores of that kind. You take one leaf or more of the Pelargonium, which you bruise upon a piece of linen; you then apply it to the sore place, and it often happens that one leaf is sufficient to heal the wound. It sticks closely to the surrounding skin, and helps to close the flesh, and heals the wound in a short time. I have often tried this method, and found it succeed well with myself, and also with others to whom I have mentioned it. The Pelargonium zonale, one of the oldest and most common in gardens, is much more efficacious than others of the same kind; its shining and fleshy leaves render it far preferable to those which are dry, ribbed, and downy. —*Rev. Hort.*, 1843, p. 464.

Plants producing Wax.—There is in Brasil, besides the well-known Corypha cerifera, two other plants remarkable for the secretion of wax in their fruit. The one is called in Brasil, Hycuiba, and grows about San Paulo; the other is called Ocuuba, and abounds in Para.—*Bot. Zeit.*

Cultivation of Onions by the Tartars.—The Tartars, who bring all sorts of vegetables to Wilna, the capital of the grand duchy of Lithuania, have a particular method of cultivating Onions. Instead of raising them from seeds, in which they do not succeed, or which appears to them too long a process, they dry and smoke in a chimney those which they wish to propagate, and in spring, when the time to plant them is arrived, they cut them diagonally into quarters, but so as not to separate the pieces entirely one from the other. They set these Onions in rows, when thus prepared, in good soil, well dug, but not freshly manured, at about 10 inches from each other, and two inches deep. These Onions increase extraordinarily, and grow large and strong.—*Rev. Hort.*, 1843, p. 449.

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSES, CONSERVATORIES, &c.

When a considerable portion of plants is potted, the stove ought to be kept pretty close for a week or two, to encourage the plants to form new roots and strike freely into the fresh soil. Many of the more robust kinds must be pruned at the roots, the old soil being first shaken from them, when they may be got into smaller pots; the larger roots will do to graft some of the same family on, or will form young plants if put in as cuttings; this is an easy way of getting a large stock of some plants, and almost any sort will grow from root-cuttings, in the spring. Plants may now be more freely watered, and the houses kept moderately moist.

Conservatory.—As a great number of spring-flowering plants are now coming into bloom, more air must be admitted; but those recently removed from the forcing-pits, and all stove plants brought in to bloom, must be arranged in the warmest parts of the house. Fresh beds of soil should now be made for all climbers that are to be planted this season, and a portion of the old soil removed, from such established ones as are known to quickly exhaust the soil, to be replaced by a fresh supply: this will be a good opportunity to cut or root-prune such climbers as have rambled over the house without flowering much for the last year or two, and where duplicates exist, this is a suitable time to cut down some of them to the surface of the ground, in order to prolong their flowering season; this is also the best way to get rid of plants infested with scales, or other troublesome insects, if care is taken to clean the remaining portion of the plants and the pillars or trellis, &c., to which they have been trained.

Greenhouse.—This is a good time to propagate greenhouse-plants by cuttings, &c., where a gentle bottom-heat can be maintained; great attention is required to keep these plants from growing too fast at this season; the least confinement is injurious to many tribes of woody plants of this department. The tops of young plants in free growth, ought occasionally to be cut off, in order to get good bushy specimens, even if their bloom is sacrificed at this stage.

Forcing-Pits.—These must now be kept more moist as the season advances. Cuttings reared in these pits ought to be potted off as soon as they are rooted. Thumb-pots are convenient for striking cuttings of favourite plants, in putting only one in each, and when they are rooted they are easily removed into larger pots with little check to the young plant. Seedlings demand all the attention you can give them now. When the least appearance of mouldiness is seen on the seed-pots, rub it off and sprinkle some dry peat or sand over the surface, and keep the pot rather dry for a day or two, when this additional covering may be shaken or blown off the pot.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

Need I ask if you have decided upon what plants the beds in the Flower-garden are to be planted with this season? If not, the sooner the decision is made the better, or you will be too late. Autumn-sown annuals may now be removed to their blooming-places, planting three or five in a patch according to the kind and size. For beds intended to be planted with half-hardy things, I plant the annuals in a line round the outside, and being pegged or clipped into shape, they form a neat and gay edging in the early part of the season, and leave the centre of the beds to be thickly planted with such plants as are intended for summer and autumn decoration. Californian annuals, such as Clarkias, Collitasias, Leptosiphons, Nemophilas, &c., sown now, will bloom almost as soon as those sown in the autumn; indeed, it is a good plan to sow a few seeds at the time of planting, as they fill up all vacancies, and prolong the season of bloom. Herbaceous borders, if not dressed over in the autumn, must be attended to immediately, and either fresh compost or manure must be added to all plants that are weakly.

Reserve Garden.—Proceed with the planting out of biennials of all kinds, and prepare a good-sized piece of ground for a sowing of Anemone coronaria, hortensis, and vitifolia. Anemones delight in a strong rich soil, and a rather shady situation in the summer season. Sow the seed, after being well rubbed in sand, in shallow drills, nine inches apart, and cover with rich soil from the compost-yard. A sowing of Ten-week Stocks must also be made on a warm sunny border; cover with litter or mats at night, until the seeds begin to vegetate. Sow likewise a general assortment of annuals for transplanting, to fill up vacancies.

Pits and Frames.—Here the work needs no pointing out; the means of providing room after the plants are potted is the greatest difficulty in most gardens. Dress dressed with Whitney's composition, at a cost of 3d. per yard, answers admirably in the gardens of Mr. Beck, of Isleworth. This is, I imagine, likely to become an exceedingly useful article, and is just the sort of material that is required after plants are first potted off. Choice annuals—such as Brachycomes, Burtonias, Vincaria ocnlata, Mesembryanthemum tricolor, Schizanthus, Clintonias, and the like—should always be potted off as soon as they are sufficiently large to handle, and afterwards be placed in a warm moist atmosphere, with plenty of air in mild weather, until they are properly established. Sow in a pan, heat Marsyna fragrans and Banksias, the different varieties of Pelargonium and Ixoneas, Convolvulus scoparius and major, and, where they are admired, the common yellow and other Lupines.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Auriculas.—Attend to directions previously given. Seed may now be sown. The best compost is sandy peat and loam. Shallow boxes or pans should be filled nearly full, and repeated well to make it settle, when the seed may be thinly strewn on the surface, covering very slightly. The blooms are now finding; mind that the trusses are not drawn by keeping the lights on too much.

Polyanthuses.—Still have a sharp look out for snails. With a very small hand-fork keep the surface of the bed loose, taking care not to disturb the fibres. If grown in pots, the soil must be occasionally stirred, keeping them moderately moist. In pruning Polyanthuses it must be borne in mind, that Mullion's Earl Grey and Clegg's Lord John Russell are one and the same flower, the former being the proper name.

Ranunculuses.—If the fine day or two last week were taken advantage of, many Ranunculus beds will have been planted; if not, the sooner the better.

Tulips.—The beds must be carefully gone over and the cracks in the soil filled up, putting it firmly round the neck or rising leaves of the flower. A blunt stick is a simple though effectual instrument to loosen the soil between the rows. Should the leaves appear cankered, the soil must be displaced and the diseased part cut away with a sharp penknife; after which operation it is necessary to keep the wound dry, which may be accomplished by placing a hand-glass over it, supported by three small forked pegs; thus ensuring a free circulation of air, and at the same time defending it from the rain. Cover the beds well on frosty nights.

Carnations.—Are now beginning to move, and diseased plants which have struggled through the winter tree-fair, are dying off. Double diligence must be directed towards the compost. The careful florist who does not mean to give a chance away, will make it all pass through his hands, so that it is almost impossible a wire-worm should escape him.

Pinks.—A few sorts worth growing are Norman's Splendid, Beauty of Weston, very fine, Creed's President, Headley's Duke of Northumberland, Kirtland's Dr. Danbeny, Pearson's Professor, Cawdrey's Lord Calthorpe, Kirtland's Gay Lad, Church's Navigator, and Bunkell's Prince Albert. All vacancies in the beds must now be made up, and the soil kept in a loose friable state on the surface. Look well to the trap for wire-worms, &c. —*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—It is now quite time that the spring shifting and regulating of Pines were finished. Where this is not the case, the plants will receive the greater check, as the roots are now active from the influence of the returning spring. The fruiting Pines should be kept at 65° or 70° by night. The whole of the Pines will now require a more moist atmosphere during the day, particularly in clear weather. It sometimes occurs that an excess of moisture in the pits causes the soil round the collar of the plants to become quite wet, and as this proves very injurious to the young roots that will be now forming at that particular point, it will be well to guard against it. Much syringing and sprinkling with the watering pot at this time has the same injurious effect. When the sun has more power, and air is more freely admitted, this otherwise useful practice may be indulged in.

Vinery.—In the early house, the leading shoots being stopped at the required length, and the laterals regularly pinched in, the fruit will be advancing fast. Keep a moist atmosphere during the day, and particularly when air is admitted. The roots in the joints of the Vines are of use in extracting nourishment from the atmosphere, and when that is kept moist during sunshine, they are longer kept in a condition to perform those functions assigned them by nature. Rub off all useless shoots from the Vines now breaking, and thin the fruitful ones, leaving the strongest and best placed, and when it can be seen which are the most promising "shows," thin them also, leaving one on each spur or side shoot. It is better to have several bunches less than the Vine could bring to perfection without injury, than one too many. Examine again the state of the heat in the outside borders, as the rains and cold weather soon chill the heating material.

Peach-house.—The roots of the Peach being numerous, and generally running near the surface, it can scarcely be too often repeated, that it is necessary to pay strict attention to the state of the border as regards moisture during the swelling of the fruit. If the border was not top-dressed during the winter, it may be done now with decayed turf and soot, or the dust from charcoal. It is quite astonishing to see how soon the roots attach themselves to the turf, if applied when the plant is growing; and perhaps this is the best time to apply it, as less of the fertilising matter is lost.

Fig house.—Those plants in pots, started in November, will be approaching maturity, and must have air on all favourable occasions. Stop the side-shoots on all the plants that have attained the desired size, above the second leaf. Keep down insects, by a free use of the syringe, till the fruit begins to ripen.

Melons.—Plants grown in pits, heated by hot water, are seldom so healthy at this season as those grown on dung beds; but by giving a little air every day—keeping at the same time a moist atmosphere, and a temperature not less than 75°, by fire-heat; on dull days—they soon become strong; and, as the season advances, they surpass in vigour those in frames. Never shade the plants till they appear to be flagging, remove the netting as soon as possible, and endeavour to get your plants to stand the heat of the sun.—*G. F.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Cutting and Raising Roots of Fruit Trees.—This may still be performed where there is a tendency to over-luxuriance. Unless in extreme cases, the roots should not be cut nearer the stem than from two to three yards. It is safer to raise the roots nearer the surface. If trees were planted shallow, in poor fresh soil, mulched with dry litter during summer, and the cropping of the borders dispensed with, the operation of cutting the roots would be seldom required.

Potatoes.—Where gardeners grow the general supply for the establishment, it is desirable to change seed with another place where soil and situation are different. A few Ash leaved Kidney may be planted on a warm border.

Protection.—Much trouble will have been requisite lately with Cucumbers, Radishes, Cauliflowers, Potatoes, Salads, &c. The chief thing to be aimed at, is not merely to keep out the frost, but to prevent the plants from being drawn up weak, by keeping them in a higher temperature when covered up, than when they are exposed to the light.

Cabbage.—Take the first opportunity to fill up all vacancies in those planted in autumn, and sow in a warm border for succession. A sort I received last summer, under the name of the "London Market," seems to be very early. For general purposes I have met with none heretofore so profitable as the Vanack. A quarter planted in the autumn of 1839 has produced plentifully to the present time.

Rantine.—In favourable circumstances, Horn Carrots, Radishes, Spinach, &c., may be sown; but, in most cases, it will be preferable to get the ground in good order, and defer sowing or planting much out of doors for a week or two to come.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—In the present state of the weather little can be done in this department.

Coppice.—While the weather is favourable, the cutting of corf rods, poles, &c., should be proceeded with; spring is the best season for such operations, as the stools make more vigorous shoots. Birch should be left until the buds and leaves are beginning to expand, on account of its being very liable to bleed.

Young Plantations.—Great injury arises to outside trees, by suffering the hedges to grow up for years before planting, or cutting them, whereby they become naked at bottom. If hedges were kept low at an early period, the outside trees would become feathered with branches to the bottom, and would form a screen

or the others. By shortening the lower outside branches in time, it would prevent them from extending to destroy the hedges, before the trees are advanced to a sufficient height above them to become ornamental as outside trees, when the lower shortened branches might be taken off if necessary. From 3 to 5 feet high, according to circumstances, is a good height for hedges. Spring is the best time to perform such work, when the weather is suitable.

Hedge-row.—Proceed with the works pointed out in the two preceding months.

Nursery Work.—Little can be done in this department, except indoor work, or trenching rough ground when the weather will permit.—*W. B.*

State of the Weather at Chiswick during the last 18 years, for the ensuing Week ending March 16, 1844.

Mar.	Aver. Highest Temp.	Aver. Lowest Temp.	Mean Temp.	No. of Years in which it Rained.	Greatest quantity of Rain.	Prevailing Winds.					
						N.	E.	S.	W.		
Sun. 10	38.0	28.6	33.3	7	0.21 in.	1	2	3	4	0	0
Mon. 11	38.1	25.5	31.8	7	0.30	2	1	3	6	1	1

March 1. Cloudy and fine; rain at night.
2. Lightly overcast with whitish hazy clouds; squally, with heavy showers.
3. Cloudy and windy; clear and fine.
4. Constant heavy rain throughout; cloudy and fine at night.
5. Overcast; cold, with heavy clouds; clear, with sharp frost at night.
6. Clear and frosty; lightly overcast; clear; slight frost.
7. Cloudy and cold throughout, very clear, with slight frost at night.
Mean temperature of the week, 3.7 deg below the average

Notices to Correspondents.

GARDENERS' CHRONICLE.—The first Number of the present year has been reprinted, and may now be had. The newspaper part has been omitted.

OUR CORRESPONDENTS will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

COMMUNICATIONS from the following CORRESPONDENTS are in type, and are only waiting till room can be found for them:—*Mr. S. S. Pettigrew, R. J., J. Wighton, W. B., W. Billingham, M. G., J. B. K. L., A Practical Man, Peter Mackenzie, C. Thompson, Gr., J. Spencer, J. M'I., R. Reid,* and *J. Alexander, J. C. S.*

APPLES.—*A Subscriber.*—Six first-rate dessert varieties in succession may be the Golden Reinette, Claygate Pearmain, Ribstone Pippin, Pearson's Plate, Herefordshire Pearmain, and Stunner Pippin.‡

ATMOSPHERIC MOISTURE.—*H. C.*—The air within your Vinehouse will be found sufficiently moist, if the soil below is kept duly watered, the wall and foliage syringed, and some warm covering drawn over the glass at night. The latter precaution will prove doubly beneficial,—1stly, on account of warmth; and 2dly, as a consequence of the glass being kept warmer, its effect in condensing moisture at the expense of that contained in the air within the frame will be diminished. The space being small, if you do not make sure of giving ventilation soon enough, you will lose your crop. ‖

BEES.—*J. W. K.*—Two of Bagster's hives were stocked with a swarm each in 1838; No. 1 on the 2nd May, and No. 2 on the 4th of June. From that time to the present No. 1 has yielded 54 lbs. of honey and one swarm, and is still strong; No. 2 yielded 30 lbs. of honey, and 3 swarms, and died during last winter. When the Bees enter the side apartments, they fasten the tin slides so securely with their propolis, that it is impossible to return them in the way directed by Mr. Bagster, and the taking of honey is effected with much difficulty and danger. The small quantity of honey obtained is not owing to a bad situation, as from a single box-hive, with a glass on the top, in the same garden, 40 lbs. of honey were taken, in 1843, leaving the Bees an abundant supply for the winter; nor was this a solitary instance.—*Beta.*

BOOKS.—*A Beginner.*—Mackintosh's Practical Gardener.

BROCCOLI.—*Rus.*—Grange's Early White and Chapple's Early Cream, if sown at three different times between the beginning of May to the end of June, will produce heads in succession from Michaelmas to Christmas. ‡

CEDARS, &c.—*S. Hl. H.*—There is little hope of recovering an old Cedar when once it is in a bad state of health, but as yours is planted in a soil which is dry and mixed with chalk, it may be improved in the following manner:—Remove the turf round the tree to the distance of about 20 feet in diameter, and then loosen the soil with a fork, so as not to injure the roots; afterwards give the exposed surface a watering with 2 gallons of sulphuric acid diluted with sixty times its quantity of water, using it when the weather is moist. When this is done the turf may be relaid. Nitrate of soda is very injurious to sickly Firs, and particularly in a light dry soil, although very beneficial to healthy young ones in a strong damp soil. A small portion of nitrate of soda may benefit your Araucaria, when it becomes well established in the open ground; but this should certainly not be applied when it is first planted, which should be done about the middle of May.¶

CHIMONANTHUS FRAGRANS.—*B. F.*—There are few plants of more easy cultivation than this. You have only to train it in an open border against a south wall, and it will take care of itself.‖

CLIMBERS.—*A Subscriber.*—The following are suitable for covering the back wall of a greenhouse: Clematis azurea grandiflora, C. Sieboldii, Cobæa scandens, Maurandya Barclayana, and Hardenbergia macrophylla. A mixture of turfy loam, peat, and sand is a suitable compost for them. On iron supports, you may train Kennedia Marryattæ and Hardenbergia monophylla.‡

CLIMBERS.—*A Gardener.*—In order to render an old root of a tree an ornament to a flower garden you may cover it with the following creepers, viz.:—Eccremocarpus scaber, Thunbergia grandiflora, T. scandens, and Convolvulus major.‡

COTYLEDONS.—*W. F. C.*—Phillyreas and Alaternus may be struck from cuttings, but it is a very uncertain way; they do much better to be layered in pots about Midsummer. In striking them from cuttings select the previous year's young wood, before the shoots begin to grow, after Midsummer, and placing them in a light sandy soil, cover them close with a hand-glass. They should be placed in a north aspect, out of the sun's rays. When the cuttings are first put in, give them a good watering; but afterwards let the glasses remain close until they are struck.¶

DOUBLE-FLOWERED ROCKET.—*A. B.*—This requires to be planted in a very large tub, or in the open pit of a conservatory. It should be allowed plenty of sunshine heat and light, but it must have age before it will bloom. The still the best it is getting into is suitable for it. The flowering of *Clerodendron Minahassæ* grows often from 6 to 12 feet before its blossoms appear. Why Stanhopea insignis does not flower we cannot tell without seeing it.‡

FABIANA IMBRICATA.—*Anon.*—This is hardy, and will flower in a north border in the neighbourhood of London.‡

FELLING.—*J. L.*—Trees which are to preserve their bark should be felled in winter.

FIR-TREES.—*W. F. C.*—The common Spruce and Scotch Fir will bear planting on a cliff near the sea, and may be kept down to 5 or 6 feet high, if the leading shoots are constantly pinched off. The Tartarian and Chinese Arbor Vitæ, or the common kinds of Cypress and Juniper, will also suit that purpose. The common Yew will likewise succeed in such a situation. These kinds will all bear cutting and clipping when young.¶

FRUIT-TREES.—*H. Palmer.*—The Marie-Louise and Bacon's Incomparable will suit you, as regards Pears; the Blue Gage Plum is not worthy of cultivation, but the Purple Gage, or Reine Claude Violette, and Royale Hâtive, are excellent. The nearest respectable nurseryman ought either to be able to supply you with the above, or procure them. ‖——*D.*—On your south aspect you may plant two Glout Morceau, two Winter Nelis, two Beurré Rance, one Passe Colmar, Elton and Knight's Early Black Cherries, and the Purple Gage Plum. On the north aspect, Marie-Louise, Comte de Lamy, two Bacon's Incomparable, the Catillac for stewing, Washington Plum, May Duke and Morello Cherries. For the east and west aspects, Knight's Monarch, Beurré Bosc, Thompson's, Louise-Bonne of Jersey, and Easter Beurré Pears; the Purple Gage, Coe's Golden Drop, and Royale Hâtive Plums; Knight's Early Black and Florence Cherries. Four good Peaches are Royale Charlotte, Barrington, Bellegarde, and Malta. ‖

GOLD FISH.—*A. C.*—Our answer was given upon the *best* authority which can be obtained. You are certainly wrong.

GOOSEBERRIES.—*H. Palmer.*—The Roaring Lion, London, Companion, Wonderful Leader, Thumper, and Eagle, are amongst the largest of prize varieties. ‖

GORSE.—*H. C.*—Your plantation of this that has an unsightly appearance, being naked at bottom, should be cut over to within 4 inches of the ground. The best season for the operation is October; but if the plants are not yet far advanced in flowering, it may be done now.‡

GRAFTING VINES.—*Z.*—The Vine may be successfully grafted either by whip or cleft grafting; but whichever mode is adopted the plant must be in leaf before the operation is performed.‖

GRASS LAWNS.—*B. D.*—Resinous sawdust is of little value as a manure for grass lawns except it is charred, when it becomes useful. Sawdust from trees that are not resinous does very well as manure when mixed with the dunghill or soaked with urine from the tank. It may also be burned, when its ashes are useful; but charring is best. ‡

HARDY SHRUBS.—*Anon.*—The following dwarf shrubs are suitable for a border:—Berberis aquifolium, Ribes sanguineum, R. aureum, Amygdalus nana, Daphne Cneorum, Calycanthus floridus, Deutzia scabra, Spiræa ariæfolia, S. tomentosa, Syringa Josikæa, Garrya elliptica, and Viburnum Tinus. In front of these the following plants will have a good effect, viz., Delphinium grandiflorum, Coreopsis lanceolata, Lupinus polyphyllus, Pentstemon ovatus, Campanula grandis, Saxifraga crassifolia, Baptisia australis, Trollius Asiaticus, and Aubrietia deltoidea. ‡

HEATING.—*X. Z.*—Use such gutters as are represented at p. 653, 1843. Two, viz., a flow and return, are sufficient for the pit of your hot house; and the same number for your other pit. For so small an amount of duty, a second-sized boiler should be quite enough.——*G. H.*—Your question demands a longer answer than we can give just now; but we will hear it in mind, and answer you soon in some detail.——*T. A. N.*—Sawdust is a bad plunging material, because it is a very bad conductor. Coarsely-sifted cinders are found by experience to be the best we have seen tried.

HYACINTHS.—*Chemical Jack.*—In order to preserve Hyacinths (which have been grown in glasses) for the next year, it is best to transfer them, after flowering, to the open air, where they can be plunged in soil, and guarded from frost, which will be sufficiently effected by mats thrown over them at night.

INSECTS.—If *A Beginner* will favour us with specimens of the Caterpillars which puncture the fruit of his Cherry-trees we shall feel obliged, but to give him any useful information without such materials is not in our power. To get rid of the Black Fly, syringing with tobacco water is considered the best remedy. To make the wash dissolve ¼-lb. of soap in a gallon of soft water, add to it one gallon of tobacco-water, and then dilute it with two gallons more of soft water. *R.*——*W. C.*—Your Pear-tree is hide-bound with the Mussel-scale (Aspidiotus conchiformis), whose history was given in last year's *Chronicle*, p. 735, to which we must refer you for a remedy. *R.*

LIME.—*Rustic Robin.*—Lime is a bad conductor of heat. All earthy substances are so. The conducting power of marble as compared with gold is as 24 to 1000. We do not like your plan. If your dung is sweetened no ill effects will arise from its vapours; but your flues will, we fear, dry it so as to injure the roots of the Cucumbers.

MANURES.—*Inquisitor.*—About 3 cwt. to an acre of Potter's guano is the quantity usually applied for kitchen-garden produce. Of this, about half of a wine-glassful to a 24-sized pot is sufficient for Pelargoniums. It should be strewed on the surface of the mould in the pot, covering it slightly with soil, and allowing it to be washed down by degrees.‡——*W. B.*—We have not seen it tried; but there can be no doubt that a good watering with liquid guano would be advantageous to fruit-trees that *require* manure. We should stir a double handful up in a pot of water.——*G. R.*—Give a wine-glassful of sup-phosphate of lime to each pot in which your Pelargoniums are to flower. Apply it as a top-dressing only allowing it to be washed down by degrees in watering the plants. ‡——*G. I. T.*—Two parts of superphosphate of lime mixed with one of charcoal, may be applied to Onions when they begin to appear above ground, or it may be mixed with a small quantity of fine soil and sown in the drills along with the seeds. It should be applied at the rate of 3 cwt. per acre. ‡——*John.*—We do not know the composition of Potter's guano. It is said to contain the same constituents as Peruvian guano, without the impurities, and with the ammonia fixed.

MORELLO CHERRIES.—*A Constant Reader.*—In pruning, leave sufficient of last year's shoots, for on such this kind of Cherry bears its fruit.‖

NAMES OF FRUITS.—*A Poor Puncher.*—1, Easter Beurré; 2, Imperfect probably, Ne plus Meurie; 3, Holland Bergamot.——*A. D.*—1, Glout Morceau; 2, Newton Pippin; 3, St. Germain. ‖

NAMES OF PLANTS.—*O.*—Double Daffodil.——*M. Y.* and a *Constant Reader.*—Pezica coccinea: not very uncommon.——*A Constant Reader.*—1, Lasiopetalum solanaceum; 2, A Clematis; 3. Apparently Clerodendrum squamatum; but what a specimen! 4, Linaria cymbalaria.——*J. W. J.*—A Clematis, and apparently the hardy C. viorna.——*Pteris.*—A small specimen of Asplenium lanceolatum.

PANSIES WITH DISEASED LEAVES.—There is nothing in your compost that would be likely to affect your plants, and the disease being confined to this particular variety (a seedling) it is fair to conclude that it arises from some constitutional defect in the plant.*

PEACH-TREES.—*M. U.*—Your Royal George Peach-tree, from which the blossom-buds drop off, is perhaps too much heated from being near the hottest part of the flue, in consequence also of which, its roots may have been too dry; or its vitality may have been weakened from the attacks of insects. You ought to shorten much the bearing-shoots, and keep the roots sufficiently moist. ‖

PEARS.—*A Subscriber.*—We have not the means of saying to whom you applied that the Pears which he sent in a box of sundry were grown as follows:—*Winter Nelis*—Chelmsford, on a wall: *Passe Colmar*, dittos: *Beurré Capiaumont*, standard: *Ne plus Meurie*, standard: *Jean de Witte*, ditto; *Marvelle d'Hiver*, wall; *Beurré Rance*, standard; *Easter Beurré*, ditto.‡——*A Subscriber.*—The following are select varieties, that are good bearers, and that will succeed well as standards:—Summary, Autumn Crassane, Flemish Beauty, Marie-Louise, Beurré Bosc, Passe-Colmar, Beurré Diel, Louise-Bonne (of Jersey), Bacon's Incomparable, Knight's Monarch, Ne Plus Meurie, Winter Nelis, and Jean de Witte.‡——*J. F. D.*—As many varieties as you can find room for, may be grafted on the same tree. In some cases, a graft of a different variety caused an improvement in the general health and bearing of the whole tree. Weak-growing kinds should be worked so as to occupy a position more upright than those that are strong.‖

POTATOES.—*Beulah.*—You will have a succession and variety enough, by planting the following:—Early Manly, Kerr's Seedling, Taylor's Forty-fold, Leathercoat, Red-coated Kidney, Irish Cup, and Bread-fruit. The old turf will assist in producing a good crop; but a little manure in addition would be repaid. For two spits 1s. 6d. and 1s. 9d. a rod is more than is generally paid. ‖——*Z.*—The Ash-leaved Kidney is one of the best varieties that can be employed for forcing, and likewise for the first crop in the open air. ‡

RASPBERRIES.—*Genys.*—You may cut down your Raspberry-canes now, leaving them about 4 feet high, and tying them neatly up to stakes of about the same height. Only 4 or 5 good canes should be left on each shoot.‡

ROCKWORK.—*A. B. C.*—Any rough materials will do, except granite and similar rocks. Near London there is little to be had except the large half-vitrified masses of bricks in the brickfields. If these are put together irregularly, in a terraced style, they look very well, and grow plants as well as anything, except masses of limestone or sandstone.

ROCK-PLANTS.—*Z.*—The following are 40 plants, that are suitable for a rockwork, viz.:—Rhododendron ferrugineum, R. hirsutum, Arctostaphylos Uva-ursi, Chamædaphne procumbens, Sedum rupestre, S. Forsterianum, S. populifolium, S. villosum, S. hexangulare, Persettia phillyreæfolia, P. pilosa, Mahonia aquifolium, Ramondia pyrenaica, Soldanella alpina, Androsace villosa, Corydalis nobilis, Phlox ovata, P. subulata, P. nivalis, Vinca minor flore pleno, Campanula pumila, Gentiana verna, Dryas octopetala, Digitalis lutea, Sibthorpia europæa, Arabis alpina, Draba aizoides, Prenanthes purpurea, P. muralis, Antennaria plantaginea, Gnaphalium arenarium, Ceterach officinarum, Polypodium vulgare cambricum, P. dryopteris, Onoclea sensibilis, Asplenium adiantum nigrum, Pteris caudata, Adiantum capillus-veneris, Aspidium rigidum, A. Lonchitis ‡.

ROOT EXCRETIONS.—*J. T.*—Since the publication of the "Theory of Horticulture" this question has received much attention, and the result is very unfavourable to the existence of such secretions. We will inquire about Beehives.

SOIL.—*J. S. J.*—As a substitute for sand, fragments of sandstone, pounded bricks, or even well-worked cinders would do, though not so well. It is probable that the silex is to a certain extent decomposed by the roots of plants; and therefore siliceous rather than aluminous or carbonaceous materials should be given them. We should also try the effect of adding bricklayers' and plasterers' rubbish, such as is obtained where old houses are pulled down.

VERBENAS.—*J. G. H.*—Procure the following 12 varieties:—Girling's Amethystina, Boule de Feu, Catleugh's Ne Plus Ultra, Youell's Princess Royal, Ivery's Purpurea perfecta, Croft's Formosa elegans, Miller's Blue Queen; Tweediana superba, Atrosanguinea, excelsa, Stewartii, and Hawardii.*

VINES.—*J. R.*—Presuming the roots of your young Vines were in good condition, the shoots, which become dried up on being readmitted into the Pine-stove, must have been injured by the severity of the frosts which occurred in autumn.‖

YEW HEDGE.—*Theresa.*—Your Yew Hedge may be very much improved by cutting it down to the height you propose; the tops should not all be cut down at once, but rather thinned out at different times; one part of each plant may be cut down this spring, another part just as the buds begin to awake in summer, and the remainder the following season, observing always to leave as many of the little twigs as possible on the old stems, and not to clip the young shoots the first season; in two years you may have the hedge quite green. Open a trench on each side of the hedge and put in some fresh loamy soil, giving the plants a good watering just as they begin to grow in summer, if the weather should prove dry at the time.¶

MISCELLANEOUS.—*Spectator.*—At the Garden of the Horticultural Society young men are received for three or four years, for improvement and final placing, at from 12s. to 14s. a week, with or without lodging, and always without board. They are received upon the recommendation of Fellows of the Society, and it is generally three years after application is made that the applicant can be received.——*O.*—Ipomœa Bona Nox will flower the first year, if sown early, and well managed; but it is usually regarded as a biennial. The Mesembryanthemum is a tender annual.——*R.*—We cannot entertain either religious or political disputes, which do not the more relate to gardening because gardeners are a party to them. If we did entertain them we should say that you are wholly wrong; for what can be more unreasonable than for a gardener to insist upon following his own religious faith, while at the same time he abuses his master for not liking men of whose faith he disapproves? If the one is free to choose, so should the other be. Would you insist upon liberty of conscience for yourself, and refuse it to your master? We hope not.——*J. W. T.*—We have had no experience with calico glazed over with Whitney's composition for shading a greenhouse. We, however, imagine that it is too transparent for that purpose. With regard to the exhibitions, see *Adv.* p. 779, 1843.‡——*H. P.*—Read the article on Cucumbers, at p. 168 in to-day's paper.‡——*Charcoal.*—The fumes from a charcoal fire are injurious to plants.——*Y. G. E.*—Respecting the spot on Camellia leaves, see p. 24 of the present year.‡——*A Subscriber.*—Whitney's transparent composition is advertised at p. 996, 1843. Respecting your Apple-trees, we recommend you to plant dwarf standards.‡——*T. H. Fenn.*—In answer to above. Toads are useful for destroying woodlice.‡——*J. W. S.*—Will find the mode of applying guano to kitchen-garden crops, given in last Number, p. 136.——*A Beginner.*—Any rough coarse cinder-siftings, for plunging material, over a tank.‡——*M. A.*—Bornett's chloride of zinc certainly preserves canvas well, and we have every reason to believe that it also answers the purpose with timber; but we have not heard of the latter being employed in the construction of hothouses.——*J. T.*—Pray say to what statement about cuttings you allude.——*B. S.*—Give your Tropæolum a good bottom-heat. ‡

ERRATUM.—In Messrs. Youell's advertisement of 2d March, FUCHSIAS should be *per plant*, and not *per pair*.

SEEDLING FLORISTS' FLOWERS.

AZALEAS.—*R. W. and Co.*—The only improvement in your seedling over the Old White, is a slight one in the general form of the flower, arising from the segments of the corolla being a little broader, consequently the divisions between them are not so deep; the surface of the flower appears to want smoothness, and the three or four irregular petals in the centre of each is a decided defect.*

CINERARIAS.—*J. C. S.*—The colour of your seedling is very bright and beautiful, but the flowers are rather small, and the petals too narrow.*

*** As usual, many communications have been received too late for answering this week.

PRESERVENCE BARLEY.

MR. CHILLINGWORTH, of Cuddesdon, near Wheatley, Oxon, planted Two Bushels of the above Barley upon 1 A. 3 R. 27 P. of Land, the produce from which was 11 C. 1 Qr. 1 lb. of Barley and 2 tons 15 cwt. 3 qr. of Straw, besides the chaff.

Persons desirous of planting any of the above wonderfully productive variety of Barley, can obtain seed of Mr. Rosser Mastery of Donnington, near Stow, Gloucestershire, at 5s. 6d. per bushel for 40 bushels and upwards, and 6s. per bushel if a less quantity is ordered. Cash Payment, or a Good Reference.

N.B.—The Barley is of good quality, and malts well. Donnington, March 9, 1844.

IMPORTANT TO AGRICULTURISTS AND OTHERS.

ANALYSES OF SOILS, MANURES, &c., are conducted by Mr. MITCHELL, Analytical Chemist (late of the Royal Polytechnic Institution), No. 3, Victoria Cottages, Stanley Road, Kentish Town.

A vacancy now occurs for one house or outdoor Pupil, for the study of Chemistry as applied to Agriculture. Apply as above.

The Agricultural Gazette.

SATURDAY, MARCH 9, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, Mar. 13 . Agricultural Society of England.
Thursday, Mar. 14 . Agric. Imp. Society of Ireland.
Wednesday, Mar. 20 . Agricultural Society of England.
Thursday, Mar. 21 . Agric. Imp. Society of Ireland.

The constituent parts of animals—the substances of which their bodies are composed—we mean the carbon, oxygen, hydrogen, nitrogen, lime, phosphorus, alkalies and acids, &c., existing in various combinations within them, are necessarily all contained in the food which they eat. In the case of herbivorous animals, therefore, it is obvious that their component elements must all exist in vegetables. With regard to plants, their constituent parts also are gathered up from certain sources. One of these is the air, the importance of which in this capacity has within the last few years been fully demonstrated by Professor Liebig; the water contained in the soil is another; all matters dissolved in that water are taken up by the plant and undergo a process of digestion within it. All the matters which a plant contains are soluble in water in certain natural conditions of their existence, and are therefore capable of being taken up by it at its root. Now, as herbivorous animals and plants consist of the same elements, the food received by them must be similar in its composition. We do not now speak of the proportion which the quantities of the various elements of that food bear to one another. In this there is doubtless a difference, and this difference is undoubtedly important in its influence on the processes of nourishment. We refer only to the fact that the same elements, unaccompanied by others, must all be present in the food both of animal and plant. Then why might not animals and plants both live on the same food—food not only the same in chemical composition but also in form and substance? There are various answers to this question, and the following is one of the reasons why this is impossible. The union of those elements which constitute the animal body is very slight; a very slight derangement of ordinary circumstances would cause a partial or entire re-arrangement of those elements, and so induce disease or death. Among the causes (poisons) which are capable of this effect are a class of substances which are not directly poisonous, but which act so in virtue of a tendency in substances that are in contact to acquire a common condition. We know that though but a little leaven be added to a batch of dough, it will spread, and the whole lump will soon acquire the condition of the small quantity which was added to it; and it is upon a similar principle that but a small quantity of matter, if in a decomposing state, whose elements may be identical with those of a living animal, may yet prove the cause of its death, if it be partaken of. The process of re-arrangement proceeding amongst its own elements, which is in fact the process of putrefaction, would communicate itself to the substance of the living body, and the leaven gradually working its way would impress its own character upon the whole mass, rendering it diseased, and ultimately depriving it of life.

The very condition, however, of food, which is thus rendered poisonous to animals, makes it peculiarly suitable for vegetables. Plants cannot consume massive food like animals; they have no mouth which can take it up in such a state, and no stomach in which to digest it. The soil answers this purpose for them, and the organic matters existing there are, under the influence of external agents, gradually losing certain of their elements, which, forming soluble compounds with others, are dissolved by water, and so introduced into the vegetable. This rotting condition—the poisonous state of food for animals—is thus the very condition in which food for plants is most valuable.

We have thus arrived at this conclusion;—there is no case in which food of an organic character, in a condition of unfitness for vegetables, can be safely administered to animals. And the point to which we wish to direct all these observations is simply this: there is, notwithstanding what has been said, an instance of daily occurrence in which such food is administered on many farms to the most valuable stock. We refer to the condition in which rotten dunghills are generally to be seen—black foetid pits, the receptacles of stables and manure heaps; and this filthy stuff is confidently asserted by many to be wholesome, and even preferable to pure water as a beverage for their cattle!

We need not quote the analyses of the various matters which thus run into many horseponds: they will be found under the head Liquid Manure, in Mr. C. Johnson's "Encyclopædia of Agriculture:" it is sufficient to remark, here, that, besides certain salts of ammonia, which are undergoing various chemical changes, and besides other soluble mineral salts, there is a considerable quantity of purely *animal matter* suspended in this water, which, under the influence of air and moisture, is necessarily undergoing a putrefactive process, and which, if introduced into the animal system in sufficient quantity, must tend to act as a leaven and to introduce that putrefactive process there, perhaps to result in death. But on this very account is this animal matter peculiarly valuable as food for plants, and united, as it is, in liquid manure with ammoniacal and phosphoric salts, it possesses the most fertilising properties. Instead, however, of being used as a manure, it is, on such farms as we allude to, suffered to run to waste; and, of all possible places to which it may run, it is allowed to select the only spot where it can be injurious.

But what a perversion of means is this! Not only is a valuable manure wasted, but it is made use of in a manner having a most dangerous tendency; that which, if applied to the crops on the land, would increase their fertility, is not only allowed to waste, but it is negligently, if not purposely, allowed to run into the very drinking-trough of the cattle—almost the only place in the wide world where it could be injurious. We say "purposely," for it is insisted on by some, that this water is preferred by cattle, nay, that it is beneficial to them. To complete the absolute foolishness of their conduct, those whom we would call *guilty* of it are, in all probability, the very parties who will cry out against what they term the want of economy displayed in erecting necessarily expensive but well-arranged buildings, calculated to hinder such waste as that we have been describing.

The prejudice, however—for if anything deserve the name of prejudice, it is this—that water, filthy from such admixture, is wholesome, seems, from the following statement received from a medical friend, to be in unison with some of the eccentricities of human nature:—"The love of filthy and disgusting remedies seems to have been by no means rare. *Album Græcum* was formerly much used in medicine; it is the white earthy remains of the bones on which dogs feed, after digestion has extracted the whole of the soluble animal matters. *Mummy* used to be a most celebrated remedy for the cure of numerous complaints, and, as it was sold at a high price, some Jews carried on a very profitable business in the manufacture of mummies for medicinal purposes; they had a regular apparatus of ovens and drying-houses for the purpose; the discovery of these, however, destroyed the public faith in the operation of what had previously been one of the most effectual remedies in the whole Materia Medica. A friend told me some years ago that there was a drawer in the shop of an old apothecary to whom he was apprenticed, labelled '*Pulvis e cranio humano*!' *Foxes' lungs* used to be highly celebrated for the cure of the asthma, the fox being a long-winded animal." Then follow remarks on the medicinal properties of matter contained in muck-water:—"The salts contained in farmyard muck-water have almost all of them a slightly purgative, and also, probably, a diuretic action. I should think that until the animals were well habituated to such potations, they would have a strong tendency to destroy or diminish the appetite, and that they would drink a less quantity than if supplied with pure and wholesome beverage. How far the decomposing animal and vegetable substances contained in this water may be capable of communicating their own process of putrefaction to living tissues I cannot tell; but I should certainly fear that such putrefying substances introduced into the stomach would increase any tendency to diseases connected with the state of the blood."

We must add to the above the following statement, received from a distinguished veterinary surgeon; it is upon the same subject—the runnings of liquid manure into horse-ponds:—"I must confess that I have not met with cases of disease that could be attributed to this cause. The urine is doubtless generally in such a state of dilution as not to be prejudicial; for it is to be borne in mind that, in its natural state, nine-tenths of this liquid is pure water. It must be given pure, and in quantity, to produce disease, unless it be in a putrefying state, when a far less proportion would be sufficient." It will be remembered, that it is because it acquires this putrefying state that we insist upon its poisonous tendency. "The effect of water rendered impure by decayed leaves is more injurious than that just mentioned. In Australia there is frequently a scarcity of this fluid, and the ponds become impure from decayed leaves, and an endemical disease of a fatal nature is the result. When water also has been in a stagnant state for some time, it abounds with myriads of minute insects; and there are instances of worms (though not of the ordinary kinds) being the result of drinking the filthy water; and inflammation of the bowels has arisen, and death has also been the consequence in a few instances. Filthy ditch-water, in a state of absolute putrefaction, is still more dangerous; but animals will not partake of it, unless suffering from extreme thirst. Disease of a low typhoid character, soon followed by death, has been the result. In all cases, animals should be provided with water as pure and as soft as can be obtained.—*W. C. S.*" Although the writer of this has never seen disease arising from the causes we refer to, yet the remarks he makes afterwards show that his opinion, valuable as the result of experience, coincides with our own, expressed above, as to the folly and danger of *thus* wasting the valuable parts of the dungheaps, and the runnings of stables and cattle stalls.

We are now busily engaged in THE PREPARATION OF LAND FOR THE CARROT CROP. That on which we intend growing Carrots this year, is a siliceous sandy soil, sufficiently rich in vegetable matter, and therefore just such as this root likes. It was broken up from old pasture four years ago, having first been efficiently drained. The first crop taken was Swedish Turnips on one part, and Potatoes on another; for both of which it was manured and limed; it was subsoil ploughed in the spring of that year; the following season it bore Wheat, along with which Clover-seeds were sown; the third year it was mown and grazed, and then broken up for Wheat, of which we had last year a heavy crop on it. All this is stated, although it involves matters unconnected with our present subject, just to show the condition in which the land is, and its suitableness for the growth of Carrots.

No principle of any importance is involved in the cultivation of this root, on which that of Turnips, Beet-root, or any other of our green crops does not also depend. There are, however, peculiarities in the cultivation of the Carrot, arising from the character of the seed, the shape of the root, and the early period at which it must be sown.

There are few soils, however severe the frosts of winter may have been, which will not, when ploughed early in March, turn up stiff, so as when harrowed to present a cloddy surface, which is not easily reduced. Now, it is important that the surface should be fine when Carrot-seed is sown; and, therefore, it is a good plan, in order to avoid the necessity of ploughing in spring, to plough in the manure before winter. We read and hear of the Carrot-crop requiring no manure, which the authorities for such statements account for by the depth to which, as it is stated, these roots descend for nourishment. It may be safely admitted, however, as universally true, that all crops require manure, and especially those which we expect to yield a weight of 20 tons and upwards per acre. The manure, which may be that of the farm-yard, should be ploughed under in October, as deep as possible, *i. e.* from 8 to 10 inches under the surface, and the land may then be left till spring. We were unable to do this at the proper time last autumn, not having sufficient on hand, and therefore we are now cross-ploughing our land before spreading the manure, after ploughing in which we shall have to harrow it repeatedly to get it ready for the seed. Had we ploughed in the manure in autumn we might have left the land till the middle of March, and then using merely the cultivator or scarifier, we should have saved the spring ploughings, and there would have been no difficulty in getting the land fine for receiving the seed.

Carrot-seed should be sown during the first week in April. About 5lbs. per acre is the usual quantity. The seeds are surrounded by stiff short hairs, so that they cling together, and in order to enable the farmer to drill them (the common Suffolk drill is used for the purpose), they must be mixed with sand. If the drill be set to sow 2 bushels per acre, 2 bushels of sand must be mixed with 5 lbs. of seed for every acre that is to be sown. It is an advantage to make the seed germinate in the land as soon as possible, and therefore it is well to mix the seed and sand together four or five days before sowing, and to damp them somewhat, so as to swell the seed, and partially to sprout it. Do not *wet* the mixture, merely damp it so that on squeezing a handful it shall preserve its form, and not crumble on opening the hand. If the sand be wet, the drilling machine will soon choke; it must be spread out as soon as damped, and turned three or four times every day before sowing; this will dry it somewhat, so as to enable it to pass easily through the drill. The seed is drilled on the flat surface in rows, from 12 to 24 inches apart. It is right to adopt such a distance as will enable the use of the horse-hoe, and 18 inches is the least at which this is practicable. We grew them in rows only one foot apart last year; but

at this distance the land could not be cultivated, and could hardly be kept clean; it became very hard, and it was probably on that account that so many roots went to seed. This year we shall adopt an average distance of 18 inches from row to row; but in order the more effectually to use the horse-hoe, we shall sow the seed in rows alternately one foot and two feet apart; the one-foot interval must be kept clean by hand-hoeing, the two feet interval we shall be able to horse-hoe; and one side at any rate of every row will thus receive the benefit of deeply stirring the land. Whenever the rows can be distinguished, the land should be hoed, and whenever the plants have come into full leaf they should be singled out. The distance at which they should be left may be 8 or 9 inches. When the land is apt to get soon covered with small weeds, not easily distinguishable from the young Carrot-plants, it is a good plan to sow a few Oats along with the seed. The Oats spring up before the Carrots, and point out the position of the future row, so that the land may be hoed when necessary, even though the Carrots are not up, without any chance of destroying the young plants. The summer cultivation of the crop consists in a repetition of the hoeing whenever necessary (this will cost at least 15*s.* per acre), and occasional horse-hoeings to stir the land. All the plants which run to seed should be pulled up whenever they are seen, and they may at once be carried to the yard for the pigs.

The best variety of Carrot for field culture is unquestionably the White Belgian. On suitable land, under good cultivation, the farmer may expect, in ordinary seasons, a crop of this root weighing from 18 to 22 tons per acre. It should be ready to harvest towards the end of October; and before then we shall return to the subject.

ON THE SOIL AND CLIMATE OF THE SHORES OF THE MORAY FRITH, IN SCOTLAND.—No. I.

From the remarks contained in the first two Numbers of your new Paper, on the necessity of a general knowledge of the soil and climate of a district, towards the right understanding of the peculiarities of its husbandry, the public, I trust, may expect soon to find in your columns a series of papers descriptive of all the principal Agricultural *districts of* the United Kingdom. Without some general notices of this sort, to which we may refer, the vast mass of detached observations accumulating in your pages may become unmanageable, and practices in one district be found quite inapplicable in others. As you will, no doubt, receive many communications from the North of Scotland, which exports a good deal of grain and fat stock to the English markets, and as throughout this district the Lothian system of husbandry is now extensively and successfully followed, it has occurred to me that a short popular account of its soil and climate may not be unacceptable to many of your English readers. In the present paper I will confine myself to the north-eastern side of Scotland, which, in fact, is also by far the most productive and important one; and in a general sense, it may be observed, that the cultivated zone in this district extends only for a few miles inland from the shores of the Moray Frith. In this district examples, yearly increasing in size and value, exist, as I have said, of a successful imitation of the best Scotch or Lothian system of husbandry, with this peculiarity, however, that throughout the Lothians the soil and subsoil have been naturally enriched by the clay and mineral alkalies resulting from the decomposition of the trap and porphyry rocks, which so universally prevail in the Southern Lowlands of Scotland, while in the northern district to which I refer, there are no secondary trap or porphyry rocks of any extent, and the clay which does occur has resulted from the disintegration of primary gneiss and granite and the older felspathic rocks, and from the breaking up of secondary shales and aluminous slates. Stiff clay loams are hence rare with us, while light sandy soils are by far the most prevalent in the Agricultural portions of the north Highlands. This results from the prevalence of sandstone rocks along the whole north-eastern shores of the country; and any deviations from this structure will be readily accounted for by attending to the following slight geological description.

The great basin of the Moray Frith appears to have been at one time filled with strata of the old red sandstone formation, having superimposed upon them members of the Lias and Oolitic series, and of other partial or local deposits as high up as the chalk, but of which latter formations only faint traces are now to be found at wide intervals along the Ross and Sutherland coasts, and in a few detached spots in Moray and Banffshires. The great sandstone pavement itself has been most extensively denuded and cut up by the ocean, so much so that it now exists only as a narrow frame-work to the primitive rocks composing the interior of the country on which it reposes—the inner boundary of the sandstone being an irregular line running generally round the whole coast at the distance of from 2 to 10 miles from the sea, except in Caithness, which county is entirely covered by this rock, whose beds are also prolonged into and constitute almost all the Orkney Islands. In many places, especially in the lower parts of the country, the rocks retain the horizontal position in which they were at first deposited, but in others they are found in undulating lines, and are often contorted and broken up by intruding masses and spurs of granite against the sides of which they are often abutted at highly inclined angles. Near Cromdale and Cawdor Castle in Nairnshire, the black rock of Inverfarikaig, and the precipices below Mealfourvonie on Loch Ness, Craigphadrick, near Inverness, the ridge from Avoch to Cromarty, the Ord of Caithness and other picturesque localities, beautiful instances of the intrusion of the amorphous granites among the sandstone layers occur, thus giving rise to much of the irregularity and boldness of our inland fastnesses, and of our projecting headlands and rocky coasts.

The sandstone, or Devonian system, and its associated beds, are divisible into three great groups:—1st. The uppermost consists chiefly of pure yellow freestones, such as those of Bishopmill and Quarrywood at Elgin, which form beautiful and durable building-stones, and which were formerly regarded as the yellow sandstones peculiar to the coal formation. 2nd. Gray and variegated sandstones, with soft bituminous and calcareous shales and flagstones; all highly charged with bituminous matter, the remains most probably of extinct marine vegetables and fishes, of which impressions and scales are still occasionally found. These beds were formerly held as occupying the place, in the north of Scotland, of the true coal formation, though not exactly identical with it; (see Murchison and Sedgwick's papers, in the Geological Society's Transactions, on the Brora Coal-field, &c., and Anderson's Highland Guide, first edition, p. 197); and many attempts have at different times been made to procure coal from the deposit, but without success. 3d. The fundamental rock of the series is the true old red sandstone, with its associated coarse conglomerate, together forming the round-backed undulating chain of hills (often presenting abrupt escarpments and finely-shaped conical summits) which encompasses the whole country, being interposed between the low plains and the high and rough primitive mountains of the interior. This sandstone, which is usually of brick-red colour and of a great diversity of texture and hardness, is by far the most abundant rock in the secondary strata; and is in general a mere agglutination of sand coloured by the red oxide of iron, though in many places it is highly micaceous and aluminous. It is the parent, so to speak, of all the superior beds, which (though at one time it was somewhat difficult to find their true geological position) have, of late, been pronounced as belonging to the same old red-sandstone formation, in consequence of the identity of the organic remains found in both the lower and the upper strata *.

In some few places, as at Linksfield, Inverugie, and Cothall, in Morayshire, and at Helmsdale, in Sutherland, irregular unstratified masses of a concretionary limestone (called cornstone), a deposit most probably from ancient hot springs, occur subordinate to the sandstones, but in general the district in question is devoid of lime; gritty quarts or sand being by far the most abundant ingredient of the rocks.

The distribution, in greater or less quantities, of the several members of the foregoing series, affects much the fertility and outward aspect of different parts of the district around the Moray Frith; and in my next paper I will shortly describe the leading features of each portion of country in which the different members respectively prevail, and then advert to the general covering of gravel which almost universally constitutes our subsoil, and will conclude with a brief sketch of our northern climate.—*G. Anderson, Secretary to the Horticultural and Farmers' Societies of Inverness.*

* The most interesting and beautiful account of the very strange organisms in these deposits occurs in Mr. Miller's "Old Red Sandstone," a work which has justly received the highest praise from the first geologists in Britain.

EXPERIMENTS WITH MANURES.

From the numerous experiments which have been made with different manures in various parts of the kingdom, on almost every variety of soil and situation, it is reasonable to hope that by a comparison of the results obtained by these means, we may arrive at something near the truth, and be enabled to form an estimate of the relative value of the substances that may have been made the subject of investigation. It is with the view of assisting in this important work, that I have received the permission of Sir Charles Lemon, Bart., M.P., to transmit you the following details of some experiments made at Carclew, in 1843, for the purpose of testing, on a small scale, the merits of certain manures, when applied as a top-dressing to growing crops; and although they are far too limited in extent for us to draw any positive conclusions from them, as to the real value or efficiency of any of the substances employed, they will probably be useful in some degree as exhibiting their fertilising powers under circumstances precisely similar in every respect.

The subjects selected for experiment were, 1, nitrate of soda; 2, sulphate of soda; 3, guano; 4, sulphate of ammonia; 5, Stott's soluble manure; and 6, drainings from the farmyard. The field considered as the most suitable for giving the whole a fair trial, was one with a high open exposure sloping to the south, where the soil is a free light loam, averaging about a foot in depth, on a yellow clayey subsoil, interspersed with spar. It had been well manured the previous season, and cropped with Turnips. After these were removed, the ground was ploughed and prepared for Barley, which was sown in the latter part of April. On the 15th May the manures were applied, the tenth part of an acre being allotted for each experiment.

1. *Nitrate of Soda.*—The quantity used was 33½ lbs., which is at the rate of about 3 cwt. per acre. It was sown by hand with the utmost care, so as to distribute it as equally as possible over the plot of ground. Little or no effect was observable for some time afterwards, owing, no doubt, to the unusually late wet weather, by which vegetation generally was very much retarded. The manure, however, did its business quietly and surely, and a change was apparent, not only in the more rapid growth of the plants, which soon outstripped those around them, but also in the colour of their leaves and leaves, which were alike remarkable, both for their greater size and the rich deep green they subsequently assumed. During the season, this plot maintained its fine healthy appearance, from which I was led to infer that nitrate of soda would prove a most valuable manure; but the result was very different to what I anticipated, the weight of the produce being, in Straw, 199 lbs., in Corn, 176 lbs., which measured 2¾ Winchester bushels, equal to 37½ bushels per acre, and less by 6½ bushels per acre than any in the series.

I was not prepared for such a difference between the weight of the Corn and Straw in this experiment, and those of the others; and I am quite at a loss to account for the deficiency. The only way in which I imagine it to have arisen, was from the plants having been stimulated by the application to become more succulent and vascular than they would have been under other circumstances; so that when they arrived at maturity, and were cut and dried, the Straw and Grain lost in weight more than their bulk and appearance would otherwise have led us to expect.

2. *Sulphate of Soda.*—The same quantity, 33½ lbs., of this salt was used as in No. 1. The large hard lumps in which form it arrived, were pounded and reduced to a fine powder. It was then sown by hand in a similar way to the preceding, and to the same cause may be ascribed the slowness of its action, no change being perceptible until warm weather made its appearance, when its effects became nearly as striking as in the previous experiment. The plants acquired a dark healthy green colour, and were upon the whole nearly as tall and luxuriant as those treated with nitrate of soda; but here again the produce was less than expected, the weight of Straw being 264 lbs., of Corn 215 lbs., measuring 4 bushels and 3 gallons, which is at the rate of 43¾ bushels per acre. In so far, therefore, as we may judge from the result of these two experiments, it would seem as if neither the nitrate nor sulphate of soda were adapted for using on this light soil. It is perfectly true that they act in some way as a stimulant to the growing plant, as shown by the places where they have been used being invariably of a dark healthy green; but I am inclined to think their beneficial effects, if any, will be found to be very transitory, and by no means so wonderful as they have been represented.

3. *Guano.*—The conflicting statements which have appeared from time to time respecting the proper quantity which ought to be applied of this manure, and the failures that have occurred from using it too bountifully, induced me to use a much smaller proportion of it than is now recommended, but, notwithstanding this, its effects were truly remarkable; for, although only 16½ lbs. were sown dry over this allotment, which is at the rate of about 1½ cwt. per acre, it could readily be distinguished during the growing season from any other part of the field. The corn tillered well, and appeared thicker than in Nos. 1 and 2, and although somewhat shorter, it was in other respects equally strong and healthy, and of a rich deep green. It deserves to be noticed that, at the time of binding up the Corn, the workmen remarked what appeared to them to be a difference in the weight of the sheaves, compared with those in the first and second plots, which they had previously bound up, and the result showed an increase over the nitrate of soda, of no less than 81 lbs. of Straw, and 74 lbs. of Corn; the weight of the Straw being 280 lbs., of Corn, 232 lbs., equal to 5 bushels, or 50 bushels per acre. Besides this experiment, I have made several others with guano in a liquid state, on vegetables in the kitchen garden, all of which have satisfied me that this manure, when unadulterated, is one of the most powerful that can possibly be employed for gardening purposes. Its effects are visible in the course of eight or ten days after its application. For Onions, Celery, and the Cabbage tribe, it surpasses anything of the kind I ever witnessed. I had portions of each of those vegetables watered with guano, without being made aware of the particular spots so treated, and at the end of a week I had no difficulty in pointing out every one of them where the guano had been used.

4.—*Sulphate of Ammonia.*—A small quantity of this salt, prepared by gas-liquor acting on sulphuric acid, produced from the roasting of copper ore, was forwarded from Bristol to Sir Charles Lemon, for the purpose of experiment, with the following directions:—"The quantity usually applied is about 2 cwt. per acre. Upon Grass-lands or growing crops it may be sown broadcast; or, in preparing the land for seeds, harrowed lightly into the ground; or it may be mixed up in any proportion with soil or any decayed vegetable matter that may be most easily procured." In the present case the quantity used was 22½ lbs., which after being reduced and made tolerably fine, was sown by hand unmixed with any other substance. A fortnight after the application I remarked a trifling difference in the colour of the young plants, which seemed to be of a paler green from those adjoining them; but this soon wore off, and was succeeded by a fine healthy green, which they retained during the rest of the season. The Corn was about the same thickness as where the guano was used, and of an average height. The produce gave of Straw, 269 lbs.; of Corn, 232 lbs., equal to 5 bush., or 47½ bushels per acre. Between this and guano there is a difference in favour of the latter of 13 lbs. in the weight of Straw, and 20 lbs. in Corn; while the difference in the cost of sulphate of ammonia is nearly double that of guano.

5.—*Stott's Soluble Manure.*—This is a preparation somewhat resembling the last, but of what it is really

…ommercial I am unable to say. It was obtained by Sir Charles Lemon, Bart., from G. L. Stott, Esq., of Ashley-hill, near Bristol, and appeared to me, from its smell, to be some putrescent urine impregnated with ammonia, on which I suppose its value as a manure principally depends. It was directed to be used at the rate of 1 cwt. to 1000 gals. of water per acre. The quantity which I applied seems to have been rather more than the right proportion, being 12 lbs. to 120 gallons of water, which was dissolved and distributed over the ground with a large watering-pot, without producing any injurious effect; on the contrary, the return of the weight of Corn and Straw proves it to have been one of the best manures in the series, although there was certainly nothing remarkable in the growth and appearance of the Corn whilst growing, to indicate its superiority over the others. It was of an average height, and dark healthy colour, but all the plots were more or less so, and from adjoining one another formed a deep green stripe down the field, which could readily be distinguished from any elevated position where the whole could be overlooked. The only difference in those cases where the return exceeded the average crop appeared to be in the plants having tillered better, and produced a greater number of stems than usual. In this instance the weight of Straw was 288lbs.; of Corn, 257lbs., which measured 5⅛ bushels, or at the rate of 53½ bushels per acre.

Drainings from the Farm-yard.—The value of liquid manure is well known to gardeners, and there is no reason why it should not become of equal importance to farmers for using on a large scale. The trial which was made of it in this instance was highly satisfactory, and confirms the opinion I have long entertained, that more attention ought to be paid to the proper formation of dung-heaps, as well as to the making and preserving of liquid manure in tanks, &c., than is the general practice. Were this the case, I am persuaded it would be far more advantageous to the farmer, than wasting his money on foreign substances whose virtues, if any, are of a questionable character; or, at all events, not more powerful than those which may be obtained, at much less cost, from other agents within reach, if the means are only adopted to secure them. Here we have the fact of the common drainings of the farm-yard giving a return equal to that obtained from the finest manure of which we have any knowledge. The quantity used was 100 gallons, or 1000 gallons per acre, not in the strong brown coloured state it appears when running from the stables, or cattle-houses, but diluted with water until it resembled what is commonly used for gardening purposes. It is difficult to make the general reader understand this, but I should think one gallon of the dark-coloured liquid, to two gallons of water, would be near about the right proportion. The appearance of the Corn was remarkably strong and healthy. The weight of Straw was 300lbs., of Corn 256lbs., which measured 5½ bushels, or 52½ bushels per acre. If the effects of guano and some of the other manures were such as to excite surprise, I think the result of this experiment will appear no less remarkable, as it supplies us with evidence in proof of the great value of liquid manure, which in too many instances, I regret to say, is either little attended to, or wholly permitted to run to waste. In this particular, I believe it will be generally admitted, there is great room for improvement; and it is to be hoped the time is not far distant when the facts derived from these and similar experiments will be the means of causing a better system of management to be introduced. A portion of equal extent to those allotted for each experiment was set apart for comparison, and found to produce in Straw 233lbs., in Corn 200lbs., which measured 4 bushels, or at the rate of 40 bushels per acre.

The subjoined Table will more readily show the results of the several experiments:—

Table showing the result of Experiments with different Manures applied as a top-dressing to Barley, 1843.

Kind of Manure.	Quantity used on one tenth of an Acre.	Price.	Produce of one tenth of an Acre.			Cost per Acre.			Rate of Produce per Acre.

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. IX.

PART III.

(*Continued from p. 139.*)

ON THE CHEMICAL COMPOSITION OF THE FOOD OF PLANTS, AND THE RELATION IT BEARS TO THAT OF THE PLANT ITSELF; FORMING THE BASIS OF THE THEORY AND PRACTICE OF MANURING LAND.

Under this head I also propose to discuss the best means of retaining or increasing the fertilizing properties of manures.

Plants having no power of locomotion must have the food by which their growth is supported and their waste supplied to them upon the spot where they grow. Now, in the proverb implies, *as sticks will not*, so from attempting to clear nothing can be more, as it is equally certain that the grain, leaves, straw, and roots of a stalk of Wheat, must have derived the material of which their fabric is composed either from the earth in which the roots are planted, or from the atmosphere in which the straw, leaves, and grain grow. Now, we have only to apply the same truth to different parts of which a plant is composed, and instead of saying that as a whole it derives its material from the earth or air, we prove that it must have carbon and the elements of water for its starch and sugar, an addition of nitrogen for its gluten or albumen, phosphate of lime and magnesia for the husk of its seed, and silicate of potash for its straw; and we have only further to prove that these elements must be present for one crop, and with variations or omissions are essential for another, and also that by the addition of individual elements, we can increase the quantity of individual produce, as azote for gluten, carbonaceous matter for starch, and we arrive at once at the foundation of Agricultural Chemistry, at the basis of those great principles which must ever guide the scientific farmer, in a judicious application of the food of plants. A moment's reflection too will convince any one who thinks it worth while to consider the subject at all, that the cause of failure, which we so constantly hear of in the application of manures, arises from the want of attention to these principles.

Let us take an example:—A farmer is anxious to try a certain manure—we will say nitrate of soda or potash; he applies it to his land according to the prescribed rules of so much per acre.

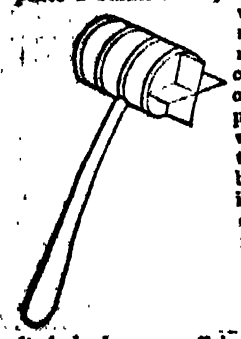
Now the nitrate acts as a manure principally, if not entirely, by supplying the alkali, soda, or potash to the soil. The Cerealia, Wheat, Barley, &c., exhaust the soil of alkali, because a union of it with silicic acid (which is formed of silicon and oxygen) is necessary for the stiffness of the stalk; and this I may observe, *en passant*, is the cause of the green, rank appearance of the corn crops to which the nitrates are applied.

But it may happen, and does frequently happen, that there is no deficiency of alkali in the soil, or that if it did exist, it has been supplied by the usual rotation of crops. Now in such a case it is obvious that the experiment must fail. Another farmer applies it where the alkali is deficient, and it succeeds; hence the discordance in experiments, of which we hear so much.

I will take a second example:—A crop of Turnips or Mangold Wurtzel, or Potatoes, is manured in part with guano and azotised manure, and with good rotten stable manure in part, and the crop from the last-named is the best. Another crop of Wheat, Barley, or Beans, shall be manured in a similar way, and that from the guano succeeds best. Now in these cases the results are strictly in accordance with chemical fact; and yet the experimenter who fails on the Turnip crop, rejects the guano as a useless increase of expenditure in his future operations. There is another source of apparent failure and consequent disappointment in the use of artificial manures, which cannot be too strongly dwelt upon: I mean the fallacy of trusting to appearances in judging of the effect of manures. If Wheat is manured with rotten stable manure and guano, or urine, the plant from the stable manure will have the freshest, greenest, and strongest appearance; but notwithstanding this, the grain from the guano or urine will be the best sample—its quality and quantity will both be superior to that in the other experiment.

Experiment—sound co-operative experiment—as Professor Henslow has so frequently urged, is the means by which these principles can be proved true or false; but no good results will ever be obtained by putting a bushel of this or that manure at random upon the first crop that comes to hand, and judging of the result from mere appearances; on the contrary, much mischief may arise, and a certain retardation of the application of one of the most interesting and important of the sciences to Agriculture. Mr. Pusey was, to a certain extent, right, when he stated that the experiment of the Duke of Richmond was the first real contribution of Chemistry to Agriculture. But this was not the fault of the science, but of those who have undertaken experiments. An experiment, as Liebig has observed, is the expression of a thought; and whether this thought is that of the chemist or the farmer, it is quite impossible to prove its soundness, unless the minutest details are attended to. Professor Henslow's schedule is an example of what ought to be done in Agricultural experiments; and even this will be improved when farmers get into the habit of making themselves acquainted with the true nature of their soils.—*C. R. Bree, Stowmarket.*

(*To be continued.*)



Home Correspondence.

Value of Green Crops.—In your last Paper it appears that Mr. Smith, of Deanstone, estimated at Bristol the value of 200 acres of Oat-straw at from 300*l.* to 400*l.* I cannot make out which sum, as the price per quarter of the Oats is not given. He estimated 100 acres of Green Crop, one-third Potatoes and two-thirds Turnips, at 1200*l.*; 100 acres of Hay at 625*l.*, and 100 acres of Old Field as pasture at 200*l.* Mr. Morton, too, in his Book on Soils has estimated that on the Whitfield Farm, consisting of 240 acres, farmed on the alternate system of green crop and white crop, he may fairly expect to make 922*l.* 5*s* 6*d.* of corn crops, and 990*l.* a-year from stock. I deny altogether that any such returns can be made from stock, and I call upon Mr. Smith to say whether he, from a farm of 600 acres, has ever realised from cattle, sheep, and pigs, any sum approaching 2424*l.*; and I call on Mr. Morton to say what actual yearly amount he has ever realised from stock on the Whitfield Farm. I have visited the Whitfield Farm twice; I was delighted with Mr. Morton's crops, both green and white Straw. His Corn crops have, I dare say, far exceeded his estimate of their amount. I have the greatest respect for Mr. Morton as a scientific man, and I feel the greatest respect for Mr. Smith, from his having introduced a system of deep draining and deep ploughing, of the advantages of which I have had practical experience; but I think they are both misleading people in putting forth the statements they have done as to the profit to be derived from stock, and I call upon them publicly to rectify their errors, or to give proof that they themselves have made their estimated profit. I farm on the alternate system of green crop and white straw crop; but with a flock of sheep, and with cattle fed in the yards on Straw and Turnips, I cannot make one-half the amount put forth by these gentlemen as the value of green crops; and I believe that for some years past, the Norfolk farmers have barely got paid for the Corn, Hay, and Oil-cake their oxen and sheep have eaten. With beef and mutton at their present prices they do not get one-half the amount put forth by Mr. Smith as the value of a Turnip-crop.—*A Subscriber.* [Did a Subscriber notice that among the expenses was that of dung for green crops—*bought*—put at 10*l.* per acre. The 12*l.*, the value of green crop per acre, is obtained by selling not only the beef or mutton made, but the dung produced also. Of course Mr. Smith did not mean that the dung should be sold or bought, either; but he estimates the total value of all sorts of produce on the one side, as well as the total amount of all expenses on the other.]

Agricultural Improvements.—As agricultural improvement is the order of the day, allow me to mention an extreme case—the expenditure of 5200*l.* on a farm of mine (Tipton Hall, near Kelvedon, Essex), that only cost 3250*l.* In due course, when the results are accurately ascertained, I shall deem it my duty to submit statistical details and drawings of the buildings to every Agricultural Society in the kingdom, in the hope it may give confidence to those who, having the means to improve their property, are doubtful as to such improvements paying a remunerating profit to both landlord and tenant. The expenditure above mentioned has been appropriated to—1st. The perfect and permanent drainage of the land with stones and pipes, 4 yards apart, and 32 inches deep—between 80 and 90 miles of drains. 2d. To the entire removal of all timber trees, which cannot be profitably grown in Corn fields. 3d. To the removing all old, crooked, and unnecessary banks, fences, and ditches. 4th. The cutting new parallel ditches and fences, so as to avoid short lands. 5th. The inclosure of waste, and conversion of useless bog into good soil. 6th. The economising time and distance by new roads, arches, and more direct communications with the extremities of the farm. 7th. The erection of well-arranged farm-buildings built of brick, iron, and slate in a continuous range, excluding all cold winds and currents of air, but open to sunny warmth. 8th. The building a substantial and genteel residence, with all due requisites for domestic comfort and economy. 9th. The erection of an efficient threshing machine, and needful apparatus for shaking the straw, dressing the Corn, cutting chaff, bruising Oats, &c., so constructed as not to injure the straw; avoiding, by its perfect action, that immense waste of grain visible in almost every truss of straw we examine. 10th. The avoidance of thatching and risk of weather, by ample barn room, with convenience for in-door horse labour at thrashing, &c., when not employable without, so as to have no idle days for man or beast. 11th. The saving of every lb. and pint of manure by a tank, (90 feet long, 6 feet deep, 8 feet wide, with slated roof facing the north, and with well and pump,) into which is received the whole drainage from the farm yard and stables. 12th. The conveyance by iron gutters and pipes of every drop of water from the roofs of each building, so as in no manner to dilute the manure in yards. 13th. The perfect drainage of the foundations of the barn, and every building on the farm. 14th. A steam-house to prepare food for cattle. I am thus particular in detail, because it is from each of the above branches of expenditure that some portion of remuneration is expected. But, during the progress of my undertaking I have been warned, entreated, and dissuaded by my farming friends, who protested that a profitable return for such an enormous expenditure was impossible; my calculations, however, were made, and mere assertions without facts and figures weighed nothing with me. Although the operations were only commenced early in 1843, the results, so far as they go, are gratifying and convincing. As one instance of success, a field of Oats sown on the 16th of May, after drainage, was harvested and stacked before another (sown two months earlier on better but undrained land) was ready to cut. Hereafter you shall have detailed statistics of every department in which saving is effected and increase produced. In a moral and social point of view, these improvements have acted beneficially. They have excited the energies of the tenant and his labourers, stimulating them to think, compare, and improve. They have awakened the attention and curiosity of the neighbouring farmers, who are watching the result, and already have they caused many undertakings in drainage, which otherwise would not have been thought of. Had I invested my money in the funds, there would have been an end of the matter; but now I have the satisfaction of having fulfilled a public duty (without injury to myself) by calling into action, temporarily and permanently, a considerable amount of labour. I conceive *that* the highest order of charity which, by providing employment to the willing labourer, confers a favour unseen, and leaves uncompromised (his most valuable privilege) his self-dependence. If every one who has the means follows my example, where requisite, there will be little need to complain of

the want of employment for our peasantry or our capital. —*J. J. Machi, 4, Leadenhall-street, London.*

On Gorse.—I can bear testimony to the merits of furze as a food for horses, as referred to by "J. Trimmer" in your Paper of the 3d, having seen it universally used in Wales by farmers; their horses are in the most excellent condition, fed on Gorse alone, and have coats as fine as carriage horses. It may be useful to those who may think it well to try the experiment, to describe the mode of preparing it; and to this end I send you a *list* of the tools used. With these the carter is expected to cut, chop, and entirely keep his two or three horses himself. They are a pair of strong gloves, a reaping-hook (or grass-hook not toothed), a chopping-block, like that of a butcher, with a raised rim of iron round the edge, and a chopper, or bruiser, of which I send you the figure. On every farm a portion of land is left for the growth of Gorse; the last year's shoots only are taken. The cattle take this food in preference to any other, except Oats. I used to buy it chopped, at the rate of three-halfpence a bushel for my riding and carriage horses, by which I gave employment to many an idle boy. On commons the poor might keep their cows during winter in capital condition by the use of this plant. In some places in Wales, where there is a water-power, they have little simple mills for bruising the Gorse; the crushing apparatus being two wooden cylinders, with iron studs of 3 inches by 1 inch square, which, in the revolutions of the cylinders intersect each other. The Gorse, being laid on the block, is chopped or pounded until it is broken up sufficiently. The head of the chopper is a cylinder of oak, of 10 inches long, and 7 inches diameter; the knives are 4 inches deep (or high) above the surface. This Gorse feeding is a matter of much more importance than may be imagined.—*Woodman.*

Pig-Feeding.—In fattening pigs I have always found a mixture of Barley and Pease-meal, moistened with milk in the best; the pigs must be rung to make them lie quiet; the sty must be warm and airy, and the sun not suffered to scorch their backs, as thin skinned white pigs are blistered by it, which not only renders them of an unsightly appearance, but retards their thriving; neither can they bear exposure to cold winds, or cold rain, or sleet, or snow, they must be kept out of all these. This is not sufficiently attended to; on many farms you see them lying in heaps shivering with the cold; in such cases thriving is out of the question; and, on the other hand, I have seen them crammed to the height of four feet with a low ceiling above them, leaving a space of a foot and a half for a current of air; in this case they looked very delicate and sickly, like consumptive subjects, and never arrived at any size or weight for their age; their constitution was undermined by being kept constantly in a pestilential atmosphere; whereas, had the door been an open-barred door, a current of fresh air would incessantly have set in and purified the place, and given the animals a vigorous habit and a doubly increased size. These extremes should be carefully avoided, and in addition too much cleanliness cannot be observed, for nothing tends more to their well-doing than dry-feet, a dry bed, and sweet air. They wallow in mud it is true in the summer, to get a coat to shield them from the sun and flies; but that only proves that they require protection from excessive heat and the teazing of flies, and all who wish their pigs to thrive will provide shelter. My pigs are never allowed to run about, as no food they can get by prowling about will compensate for the loss of flesh sustained by the continual state of motion. In a farm it may be very well to have some running about to pick up dropped offal, but where the pigs are regularly fed with a sufficient supply, it is a thriftless plan to waste by exercise the flesh that by a state of rest would make a good return for the food consumed and the expense of attendance.—*J. Steele.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A Monthly Council was held at the Society's House, in Hanover Square, on Wednesday, the 6th of March; present, the Right Hon. Earl Spencer, President, in the chair, Lord Worsley, Lord Portman, Colonel Austen, Thomas Raymond Barker, Esq., Samuel Bennett, Esq., G. T. Bonanquet, Esq., Thomas William Bramston, Esq., M.P., W. R. Browne, Esq., F. Burke, Esq., Colonel Challoner, F. C. Cherry, Esq., Henry Colman, Esq., J. C. Compton, Esq., M.P., P. Davies Cooke, Esq., Ralph Etwall, Esq., M.P., A. E. Fuller, Esq., M.P., Humphrey Gibbs, Esq., Brandreth Gibbs, Esq., Stephen Grantham, Esq., W. Goodenough Hayter, Esq., M.P., W. Fisher Hobbs, Esq., John Hudson, Esq., W. H. Hyett, Esq., Sir John V. B. Johnstone, Bart. M.P., Rev. Charles Edmund Keene, George Kimberley, Esq., John Kinder, Esq., Bickham King, Esq., Sir Charles Lemon, Bart. M.P., William Miles, Esq., M.P., Philip Pusey, Esq., M.P., Francis Pym, Esq., Professor Sewell, William Shaw, Esq., John Villiers Shelley, Esq., Edward Solly, jun. Esq., Professor Spooner, W. R. Crompton Stansfield, Esq., M.P., Charles Hampden Turner, Esq., and George Willbraham, Esq., M.P. The following gentlemen were elected Members of the Society:—

Buckling, Rev. R., Dantsbourn Abbots, Cirencester, Glouc.
Spooner, William C., V.S., Southampton.
Wharton, John Thomas, Skelton Castle, Guisborough, Yorkshire.
Wade, Rev. Albany, Elton Rectory, Stockton-on Tees, Durham.
Garland, Joseph, Woolgrot, Wareham, Dorset.
Berwick, Rt. Hon. and Rev. Lord, Cleveland Row, St. James's.
Thompson, George, Jun., Prestwood, Stourbridge, Worc.
Rous, T. B., Court-y-Rala, Cardiff, Glamorganshire.
Townshend, Lee Porchar, Wineham, Northwich, Cheshire.
Symonds, John, Broad Windsor, Beaminster, Dorset.
Samson, Thomas, Kingston-Russell, Dorchester, Dorset.
Valzey, Joseph, Whitcombe, Dorchester, Dorset.
Homer, John, Martinstown, Dorchester, Dorset.
Long, Francis Stephen, Bulford, Amesbury, Wilts.
Cantrell, Charles Seward, Jun., Old Windsor, Berks.
Loader, Caleb, Gomeldon, Salisbury.
Nockolds, I. A., Stanstead, Essex.
Havers, William, Bacon's Farm, Mountnessing, Ingatestone, Essex.
Foakes, Charles L., Ramsden-Bell-House, Billericay, Essex.

The names of twelve Candidates for election at the next meeting were then read.

Finances.—Mr. Raymond Barker, Chairman of the Finance Committee, presented the Report of the receipts and expenditure of the Society during the previous month, and of the several cases of defaulters whose subscriptions were in arrear. The Council having confirmed the preceding part of this report, proceeded to take the concluding portion into mature deliberation, and at length agreed unanimously to the following Resolution:—

"That a professional person shall be appointed to write letters demanding arrears of subscription to all such parties as shall be designated from time to time by the Finance Committee; and in the case of such applications not being successful, to take further legal steps for enforcing the payments due."

Southampton Meeting.—Mr. Miles having reported to the Council his communications with Colonel Henderson, Mayor of Southampton, in reference to the notice of motion given by Mr. Shelley, at the previous Council, of which he (Mr. Miles) had been the chairman, Mr. Shelley proceeded to state the grounds on which he had given such notice of his intention to submit to that meeting a motion for the re-consideration of the place at which the Country Meeting of the present year should be held. He detailed at considerable length the whole succession of proceedings which had taken place in reference to the arrangements which had been attempted to be made in the definitive settlement of the various points connected with the business of the Meeting, a practical difficulty having been started on almost every question regarded by the Society as finally [illegible] duly, as one of the Stewards appointed by the Council, to lay before them at their present Meeting, the whole state of the case, in reference to the points on which such difficulties had been raised. Having done that, he was happy to find that a deputation of the Authorities of Southampton was then in attendance, and prepared, in their interview with the Council, to submit such terms for their acceptance as would render the further proceedings in the arrangements for the Southampton Meeting both satisfactory and secure. Communications from his Grace the Duke of Richmond, Mr. Mayes, the chairman, and Mr. Trew, the treasurer of the committee of the town and neighbourhood of Southampton; Mr. Bulpett, late Mayor of Winchester, and Mr. Burn, high-constable of Brighton, having been laid before the Council, the following deputation from Southampton were received, namely:—

Col. Henderson, Mayor of Southampton.
Edward Mayes, Esq., late Mayor and Chairman of the Local Committee.
Geo. W. Johnson, Esq., Hon. Sec.
Thomas Trew, Esq., Treasurer.
W. C. Spooner, Esq., and
John T. Ekless, Members.
} of the Local Committee.

The deputation having been received with every mark of respect by the President and Members present, proceeded to express the regret they felt in common with the inhabitants of Southampton and its neighbourhood, that any difficulty should have arisen in the practical details connected with the arrangements for the ensuing meeting in that locality. The Mayor could assure the Council that the occasion of that meeting was the subject of the most lively interest to every person within that district, and the mere apprehension of a removal of the meeting to another place would occasion not only severe disappointment but considerable loss both to individuals and the railway and other companies, all of whom, in anticipation of the occasion, had gone to considerable outlay in providing accommodation of every kind for the numerous visitors expected to be present. The deputation, in conclusion, submitted to the Council the choice of various propositions which they were authorised to offer for their acceptance. The deputation having retired, the Council proceeded to discuss in detail the subject of the propositions then brought before them; and on the return of the deputation to the Council-room, the following stipulations were unanimously agreed to by all the parties present, viz.:—

1.—The Council accepts the 1000*l.* paid into the hands of Messrs. Drummond by the Southampton Committee, for the use of the Royal Agricultural Society of England.

2.—The Southampton Committee are to provide and prepare in a satisfactory manner, from the three sites offered, such sites as shall be determined upon by the Council for the show-yard and pavilion, free of all expense.

3.—The Southampton Committee shall guarantee the use of the Victoria Rooms and grounds; the Guildhall and its house, and other rooms; the registration of lodgings; the lands already selected for the trial of implements and experiments—free of all expense.

4.—The Directors and Directors shall proceed to-morrow to Southampton, to select the different sites, and report the same to a special council on Thursday, the 14th of March, for confirmation.

The Mayor expressed to the Council the satisfaction he felt in this final decision respecting the place of the meeting, and the stipulations then agreed to, the communication of which, on his return to Southampton, would, he knew, occasion the most lively gratification throughout every class of the inhabitants, who were fully prepared in every way to greet the Society at its ensuing meeting in the most cordial manner. The deputation having withdrawn, the Council proceeded to receive from Colonel Challoner, the vice-chairman of the General Southampton Committee (in London), the Report of their proceedings during the preceding month. The following programme, prepared by the Committee, was approved and adopted by the Council.

Programme of the Arrangements of the Society's Show at Southampton.

Thursday, July 18.—Last day of receiving Implements, Wheat, Barley, Seeds, &c. to be exhibited in the Implement-yard, and arranged by the Stewards for the Judge's inspection.

Tuesday, July 23.—The Implement-yard open to the public from eight in the morning till six in the evening, at 2*s.* 6*d.* each person. The public exhibition of the working of the Implements to take place at Mr. C. Gaters', Swathling Farm, at twelve o'clock. Cattle received in the Show-yard from eight in the morning till four in the afternoon.

Wednesday, July 24.—The Judges inspect the Stock, and award the Prizes. The Implement-yard open to the public from eight in the morning till six in the evening. Admission, 2*s.* 6*d.* Council Dinner in the Victoria Archery Rooms, at Five o'Clock; when the Judges' award of prizes (with the exception of those for Horses), will be read. Doors open at four.

Thursday, July 25.—The cattle and implement-yards open to the public from six in the morning till one o'clock in the afternoon, admission 2*s.* 6*d.*; and from one, till six in the evening at 1*s.* Dinner of the Society in the Great Pavilion at Four o'Clock. Doors open at Three.

Friday, July 26.—Cattle-yard open at seven; sale to begin at Nine for Ten o'Clock precisely.

Stewards of Departments.—*Cattle*, Hon. Capt. Spencer, Mr. Druce, Mr. H. Gibbs; *Implements*, Mr. Miles, Mr. Shelley; *Finance*, Colonel Austen; *Sale of Tickets*, Mr. Wilson; *Receipts and Admission to Show-yards*, Mr. Barker; *Pavilion and Council Dinners*, Col. Challoner; *Ladies' Gallery*, Mr. Etwall; *General Arrangement of Show*, Mr. B. Gibbs.

By order of the Council, Jas. Hudson, Sec.
London, March 6, 1844.

By the 15th Regulation of the Society, all persons admitted into the Show-yard shall be subject to the Rules, Orders, and Regulations of the Council.

N.B.—Sale of Tickets for the Pavilion Dinner to Members of the Society at the Pavilion from Nine until Four o'Clock on Wednesday, the 24th of July, and from Eight until Three o'Clock on Thursday, the 25th of July—Price 10*s.* *each!*

Implement Regulations.—Mr. Shelley, as Chairman of the Committee for taking into consideration the best mode of arranging and adapting for immediate publication the Regulations for Implements at the Southampton Meeting, proposed by Mr. Miles and Mr. Gibbs, reported to the Council the resulting schedule of regulations, unanimously agreed to by the committee. The Council adopted this report, and ordered a copy of the regulations to be sent by post to each exhibitor of implements at the Bristol and Derby Meetings.

Annual Country Meetings.—The Council resolved, on the motion of Mr. Miles, that in future all replies to queries on the subject of the capabilities afforded by any particular locality for holding the Annual Country Meeting of the Society, and required by the order of Council in December 1841, prior to the selection of any town for such place of meeting; and all applications made to the Council in favour of particular towns within the district of any particular year, shall be laid before the Council by the first Wednesday in April of the year preceding that in which the meeting is to be held, in order that the Council may be enabled to ascertain by personal reports the actual facilities and capabilities of such proposed locality before their final selection, agreeably with the bye-laws, on the first Wednesday in the May ensuing.

Mr. Miles also gave notice that he should move at the next monthly Council: "That in future the place of holding the annual country meeting shall not be decided upon until a Committee (of whom at least three shall have acted as Directors or Stewards of the yard) shall have visited and inspected the several towns and their localities, and have reported upon their respective fitness for the purposes of the Society."

Prize Essays.—The Sixty-five Essays reported by the Secretary as received by the 1st of March, in competition for the Prizes offered for the present year, were referred by the Council to the Journal Committee.

Farm-yard Manure.—Mr. Pusey, as Chairman of the Journal Committee, has reported the adjudication of the Society's Prize of 15 Sovereigns, for the best Essay on the Mode of Management and Application of Farm-yard Manure, to Mr. John Clarke, of Long Sutton, Lincolnshire.

Communications were received with thanks from Mr. Colman, Mr. Isaac Clapp, Mr. Denison, M.P., Mr. Purchas, and Mr. Falconer.

The Council then adjourned to Wednesday next.

ROYAL AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

At the meeting of the Council on the 29th ult. the Secretary stated that he had addressed a circular letter to the foremost of the different grand juries in the province of Leinster, requesting them to originate a local subscription in their different localities, for the purpose of defraying the expenses of the next great Cattle-show of the Society, in Dublin, in August, similar to the funds which were raised in the provinces of Ulster and Munster for the same purpose. His Grace the Duke of Leinster had intimated his intention of contributing 200*l.* upon the occasion, and other large proprietors had communicated their intentions of contributing liberally also. Replies were received from 40 local societies, complying with the terms of the resolution for qualifying them for the central society's premiums this year. It was expected that almost all the existing local societies, now amounting to 100, would be enabled to qualify before the 1st of May next. The committee, upon the reports on thorough draining, for the Society's gold medal, reported that they had selected the four first competitors in point of quantity, pursuant to the terms of the original article, namely, Lords Dufferin and Claneboy, Ballyleidy, 154 acres—John Andrews, Esq., Comber, 129 acres—Sir Richard A. O'Donnell, Bart., Newport, Co. Mayo, 127 acres, and the Earl of Courtown, Co. Wexford, 104 acres; and, as all these lots professed to be equally well executed, and strictly according to Mr. Smith of Deanston's principles, it was resolved to apply to that gentleman himself, to know whether he could conveniently undertake the personal inspection of these four different places, in order to ascertain whether, in his judgment, they had complied with the terms of the original resolution, and the secretary was directed to communicate with Mr. Smith for the purpose. The reports of the different competitors were most elaborate, and carefully prepared, and, it was thought, would form a foundation for a most valuable volume of the Society's Transactions for the present year. The secretary laid the balance-sheet of the receipts and expenditure of the Society, for the year 1843, on the table, as prepared by Mr. Corlett, the accountant appointed for the purpose, which was ordered to be referred to the finance committee, previous to the next half-yearly meeting of the Society, which was fixed to take place on Friday the 19th of April.

FARMERS' CLUB.

Chepstow, Feb. 26th, 1844.—The subject for the evening's discussion,—*the best manner of cultivating Sainfoin, and the land best adapted to its production*,—was introduced by Mr. C. Blunt, who said, "I consider that a great deal of the stony, hilly land in this neighbourhood ought to be cultivated with Sainfoin; I know from experience that it would pay better under that crop than any of our meadow land. To grow it successfully a dry soil is indispensable, and with that proviso it will flourish on most soils. I do not know if thorough draining will sufficiently alter the nature of Clay so as to adapt it to the growth of Sainfoin, but I think such land could never be made so congenial to the habits of this plant as the other descriptions of soil. The first step in the cultivation of Sainfoin is thoroughly to clean the land intended to be sown. The best manner of putting in the seed is with a spring crop of corn, neither too early nor too late; because I have found the young plant, just as it comes out of the ground, is too tender to bear frost; and if late, and dry weather should set in, the seed is very apt only to vegetate partially. I think it may be sown any time from the beginning of March to the middle of April. The best way of putting the seed in the ground is to drill it 6 inches wide, because when sown broadcast it is difficult to cover. I should recommend 4 bushels per acre to be drilled, and 5 bushels to be sown broadcast; and I think it better not to sow any clover or grass seeds with the Sainfoin. The crop should be allowed to stand for seed the first year, and not be cut too low. I am of opinion there cannot be a more useful grass. It is invaluable for lambs in the fall of the year, but should never be grazed in the winter or spring. It not only prevents the lambs from scouring, but I have often cured some of this complaint by putting them on the Sainfoin. It is very early at harvest, and very easily made into hay, in good weather only requiring to be turned once; and it should not be shaken more than can be avoided. It should be cut for hay when in full blossom, at which time the flowers are red, and as soon as they turn blue the hay is fit to carry. It is not liable to heat in the stack. It will last many years mowed every year, without manure, and when broken up will leave the land in much better condition for Corn than when laid down. I recommend none but new seed to be sown; the husks of old seed become so tough as to prevent it from vegetating. I consider the crop to be in its prime about the fifth year, though it will last as good for several years. I have grown about 25 bushels of seed to the acre, and have found the straw excellent to cut for horses after threshing out the seed, and sheep will eat it much better than clover, owing to the stems of the Sainfoin being sweet and the clover bitter."—Mr. R. Phillpotts recommended yellow Trefoil to be sown with the Sainfoin, because it insured a crop the first year and then died off without injury to the latter. Another member said he once sowed red Clover with Sainfoin, and had a good crop of the former the first year, but the latter never came to anything, which he attributed to being injured by the clover.—Mr. C. Townsend said he had sown the worst piece of land on his farm with Sainfoin, and had cut three waggon loads of hay per acre every year since. Mr. Blunt added in conclusion, that Sainfoin would do very well on stony land if the roots could get between the stones; but if the soil were very thin, on a flat rock, it would be likely to burn up in the summer.—*A. Hall, Sec.*

Macclesfield.—At the late annual meeting of this Club, Mr. Carbuck delivered a lecture on Organic Chemistry in its relations to Breeding and Feeding. He detailed and illustrated at considerable length Liebig's views on this subject. In the conversation which ensued at the close of the lecture, he stated his belief that there are perhaps as many good horses now as there were 50 years ago; but the number of bad ones had greatly increased. M'Culloch had stated there were 1½ million of horses in Great Britain; and he believed he should not be far wrong in affirming that two out of every ten were not worth the food they consumed. He believed also that 8 good horses would do more work than 10 bad ones. (A member called out, "More than 20.") If by an improved system of breeding, and the introduction of better horses, they could get rid of only one horse out of 10, there would be a saving to the country, in the rearing only, of more than 2,000,000*l.* a year, reckoning the cost at 5*l.*, a year; and an equal amount would be saved annually after the rearing to 3 years old, supposing the cost of keeping the horse to be 15*l.* per annum. In reply to Mr. Prater's observations, Mr. Karkeek gave it as his opinion that a two-years old filly was too young to breed from. Her powers were not properly matured. He thought they ought not to breed from a mare under three years old. With reference to the Yorkshire horses he said, that at the last meeting at Doncaster of the Breeding Society, they boasted of their having the best sheep and cattle in the world, but actually acknowledged that their breed of horses had deteriorated very considerably within the last few years.

Probus.—At the last meeting of this Club, in consequence of the absence of the member whose place it was to introduce a subject for discussion, the attention of the Club was directed to some experiments reported in this Paper by Dr. Lyon Playfair (see page 59) which had been lately instituted on "Whitfield Example Farm," by Lord Dunie, on the feeding of sheep in sheds. Mr. Doble, of Bartelver, stated his intention to test the accuracy of this experiment on his farm, and sheds will soon be erected for the purpose. There cannot be a doubt that the exposure to the cold winds abstracts the heat rapidly from the bodies of animals, and consequently a much larger supply of food is requisite to support the proper temperature, which excess of food, as Professor Playfair has plainly shown, is entirely lost to the farmer and the country at large.

Reviews.

Treatise on Alkali as a Manure, showing its Cheapness and Efficiency for increasing the Productiveness of the Soil. Dedicated by permission to the Right Hon. the Earl Spencer. By Hugh Waterton, Esq. G. Philip, South Castle-street, Dublin.

This pamphlet contains some useful ideas on the subject of manures, which we do not remember ever before to have met with. We do not allude at present to what the author states of the action of common salt on the ammonia arising from dung-heaps. He is wrong in some of his chemical statements. Ammonia is *not* a compound of hydrogen, nitrogen, and carbonic acid. This is the composition of its carbonate. And with regard to the alleged action of salt on this substance, to which a prominent place is given in this pamphlet, as we hope shortly to adduce evidence of high chemical authority upon the subject, at present we leave it. Neither do we speak of the importance which the author attaches to the alkaline bases of most of the artificial manures, to the comparative exclusion of their nitrogenous ingredients, except only when occurring as ammonia or its salts. In this we believe he is wrong—the nitrogen contained in nitrates of soda and potash contributes to the value of these manures, more or less than the alkalies united with it, according to the condition of the land to which they are applied. The relative value of the different portions of any food, whether given to plant or to animal, is not fixed, but depends upon the wants of the plant or animal, and on the nature and quantity of the food already supplied to them. But we refer to remarks made towards the close of the pamphlet, upon the economical application of manures. We all acknowledge, in the case of the tradesman, that it is his interest to turn his money over as often as possible during any given period; and though this truth is equally applicable to the farmer, yet in practice he seems to deny its applicability.

"It is a common observation amongst farmers to say, 'I have given such a field a dressing it will not forget for years.' Upon reflection it must strike any one that this is a most improvident mode of proceeding."

It is so for two reasons: 1st, because as the author immediately states, the manure, if not all absorbed by the crop to which it is applied, is liable to waste during periods when the land is not under crop; and 2nd, because that portion remaining in the soil after the first crop is so much capital lying useless till the second and third or fourth crop, before which it is not all consumed. Hear Mr. Waterton:—

"The practice of using strong and lasting manures, as they are termed, has generally been most approved; and the artificial or highly concentrated substances, which have lately been introduced, have failed to give satisfaction to the Agriculturist, from their evanescent nature, and from the supposition that they exhaust the soil. The small cost of these substances is overlooked, and, because they act but for one year, they are turned aside as new-fangled things, fit only for the experimental farmer. If is the general usage to put bones upon land in such large quantities, that they are, from the great expense thus incurred, out of the reach of the majority of our farmers, and landlords are often compelled to advance the requisite capital. If another mode of applying the bones were adopted, this would not be necessary, and the gain to the farmer would be considerably greater than it is at present. Ten or fifteen per cent. is generally given by tenants for the advance of capital to buy bone waste, and the virtue of the bones is said to last fourteen or fifteen years. Now it is quite certain that if the land derives benefit in the fifteenth year after the bones have been used, it must be that some of them have remained all that time undecomposed, and, consequently, fourteen years must have elapsed without any good result, except from the portion that has annually been absorbed by plants. If 100*l.* is laid out in bones, and fifteen acres of grass are top-dressed with them, and their effects are visible for fifteen years, the first return of profit can only result from that portion of the bones that has become immediately decomposed, and entered into the composition of the plants; and suppose that portion to be one-fifteenth part of the bones, then 6*l.* 13*s.* 4*d.*, or one fifteenth of the capital borrowed, enables the farmer to pay the interest agreed upon; the remaining fourteen parts having to wait each succeeding year till the whole quantity has been decomposed. Now if the 100*l.* worth of bones were so prepared as to come into operation all at the same time, 225 acres, or fifteen times the usual quantity, could be top-dressed, and the return for the capital would be 223*l.* However exaggerated this statement may at first appear, nevertheless it is perfectly true, and must be the consequence of employing substances that require years to convert them into food for plants. So sensible are the Dutch and Belgians of the advantage of supplying their land annually with manure ready for immediate use, that they take great pains to prepare every substance that can be used with advantage, in such a manner as to be made available by the crop intended to be sown; and where circumstances will allow them, they supply the plants themselves rather than the soil."

These are very useful remarks, and ought to be influential. We certainly should not like our land to be *wholly* dependent, for the crop it bears any year, upon the manuring we had given it that year. There must always on well cultivated farms be *a certain amount of capital* invested in cultivation, which lies dormant from year to year—which the farmer in part invested when paying his predecessor for the cultivation in the land, as it is termed, and which he expects to receive again only when he gives his farm into the hands of his successor. But there is no necessity for his investing, besides this necessary sum, an annual amount in the purchase of manures, applied in such form and quantity that the profits resulting from them shall not be fully obtained till 10 or 15 years have run their course. He has already invested a considerable sum, which is now lying idle; he surely is not anxious to add to that sum, and allow the increase to lie as long dormant as that to which it is added.

With regard to this work generally, the one prominent idea which runs throughout it, is the alleged action of common salt on the carbonate of ammonia, erroneously called "ammonia" by the author. On the subject of this action he ought to have adduced specific evidence, as he must have known that it is disputed. It was too much to suppose that farmers would wholly change their present mode of managing manures upon a statement (whether of a fact or not we do not now stop to inquire) brought forward unsupported by evidence of any kind.

Miscellaneous.

Application of Liquid Manure.—Put it into a large barrel, and sprinkle it upon the thinnest or shallowest parts of the field lying nearest to the steading, in a way similar to the plan adopted in watering the streets in large towns. The way in which I have myself applied it is as follows:—I annually carted from a moss lying on the side of the river Tweed, from 150 to 200 square yards of the moss. This I lay down in a long heap wherever most convenient, along each side of which I place lime, amounting from 60 to 80 bolls. I then mince the moss and mix it up with the lime; in that state it is allowed to lie for nearly twelve months, after which I put it into the artificial pit formerly mentioned, where it remains for about another twelve months, or until it is required for manure to the Turnip crop. During this period, the urine, which the manure cannot absorb, escapes by the covered drain, and is spread over the mass in the pit by means of wooden conductors, or small drains cut on the surface, changing them as circumstances may require, until the whole mass is thoroughly saturated. I shut up the drain of communication in the month of April, when I again turn over the moss in the pit, which has a tendency to pulverise and reduce it. For some years past the moss has been nearly exhausted, and as a substitute for it, I have been in the habit of lifting the soil from the foot ridges, these, from the constant carting on them, being of little value. The only difference of preparation is, that the earth may at once be carted to the pit, and there mixed with lime, whereas it is absolutely necessary, in the case of the moss, that its antiseptic qualities should be counteracted before being subjected to the urine, as I have found from experience, unless that is done, it neither decomposes nor absorbs one-third of the urine in the same time. Where good moss can be procured, I would give it the preference, from the facility with which it is dug out; besides, in its natural state, it is much lighter, and altogether free from stones. I also find that moss, when prepared as above, absorbs more urine in a given space than earth can. This process I repeated every year previous to the introduction of bone manure, but since then, from the great weight of the compost, I never apply it, save to the knolls or light-

land lying in the vicinity of the steading, using bones on the more distant parts, so that, generally speaking, I only empty the pit every alternate year. The mode I apply it on the steep land, is to lay it down in heaps with as much regularity as the nature of the ground will permit, then commence spreading it on the surface in the same direction I intend running the drills. The plough follows closely after the spreaders, collecting the compost into the centre of the drills by going once round them. Its application on level land is the same as other farm manures. Having accidentally mentioned bone manure, I beg to state the following as bearing upon this subject, and which was communicated to me by a farmer in this district. Last season he applied urine to his bone-dust in such quantities as not to prevent, but encourage, fermentation. In the course of three or four days he turned over the bones again, saturating them with urine. In this state they were put into the drills; the result of which was, that the bones thus prepared produced a much heavier crop of Turnips than where the same quantity was applied to land of the same quality, and sown at the same time without any preparation, so much so, that it was apparent to the most casual observer. Whether this was to be attributed entirely to the effects of the urine, or other causes combined, I shall not presume to say.—*Mr. Alexander, Easter Haprew, Peebles.*

A new Insurance Company.—A meeting was lately held for the purpose of forming a mutual insurance company, to be called "the Vale of Aylesbury Association to protect the Property of the Members from the now prevailing Distemper, the *Pleura Pneumonia*," which in the last season has become very general amongst cattle. Some graziers in the neighbourhood have suffered to an alarming extent. The society is based upon the one formed at Sudbury, and has, with a few alterations, adopted their rules. The meeting, which was numerously attended, was presided over by Mr. J. K. Fowler. A secretary was appointed at a salary of 15*l.* per annum, and the society may now be said to be in operation. The subscriptions are in accordance with the number of cattle entered by each member, which are insured by a payment of 1*s.* per head per annum, to be paid in half-yearly payments to the treasurer, Mr. Wing.—*Aylesbury News.*

Prevention of Potato Failure.—My seed-Potatoes last year (1842) were raised before they were perfectly ripe, and I have had no failure. Nearly all the seed I planted this year, however, was the small unsaleable tubers planted whole, rejecting the very smallest. The crop was very healthy and productive. Indeed I have never seen a failure where small Potatoes uncut are used for seed; and I believe this uniform success to arise from the small Potato being unripe when taken from the ground. This opinion rests on the assumption that all the small Potatoes of a crop have not reached maturity when the rest of the crop is ripe, as being the last formed. If this be so, it strengthens the common opinion that the less ripened Potato of the upland districts makes the best seed. But at the same time we see how good seed may be had without the trouble or expense of a change from a late district, if we either plant the small Potatoes of our own crops, or raise a portion for seed before they have reached maturity.—*Mr. Caird, in the Journal of Agriculture.*

Coal Tar as Manure.—A communication was read at the Bath Agricultural Society on the subject of the value of coal tar as a manure. The writer stated that in 1840 he published his experience on the subject; he had now used it as a manure for seven years, and had never found it to fail when properly applied. By means of a watercart he distributed over his Wheat-stubble 180 gallons to the acre, allowing it to remain there two or three months in the autumn before being ploughed in. Its cost was a half-penny a gallon; it was economical, and valuable for Carrots, Turnips, Potatoes, and all roots. He had tried it on seeds, but not with equal advantage on Wheat. It was very useful on a sandy loam, resting on a marl subsoil; next to that, a deep clay land was best; but its least beneficial effects had been upon soil resting on an oolite formation.

Sale of Grain by Weight.—Before the introduction of this system, the farmers were often inattentive to the degree of preparation that was necessary, in order to remove all the light grain, and the most experienced may be deceived by grain appearing plump and round, yet found deficient in weight, and consequently in real value; but the corn-merchant has more confidence to give a good price for a good sample when he is fully assured that it is not at all deceptive. I am also a farmer myself, and can state with perfect confidence that to the farmer the system has been most beneficial; it is not only a guarantee that any trouble he may be at to cultivate and prepare a good sample of grain will be rewarded, but it also induces him to adopt the best method of producing it.—*Mr. Cruickshank.—Dublin Farmers' Gazette.*

Notices to Correspondents.

Rural Chemistry, By Edward Solly, Esq., F.R.S., Experimental Chemist to the Horticultural Society of London, Hon. Mem. of the Royal Agricultural Society, and Lecturer on Chemistry at the Royal Institution, has been reprinted from the *Gardeners' Chronicle*, with additions, and may be had of all booksellers, price 4*s.* 6*d.*

Our Correspondents will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

Books.—*A Subscriber.*—Low's "Practical Agriculture," Martin Doyle's "Practical Husbandry."—*Northumbriensis.*—J. Lindley's "Introduction to Botany," Metcalfe's "Withering;" Dr. Reid's "Chemistry of Nature," Dr. Reid's "Elements of Practical Chemistry," Lyell's "Elements of Geology," De la Beche's "Manual of Geology," Morton on "Soils," and Jameson's "Mineralogy." Thanks for your suggestion.

Barren Chaff.—*Nodus.*—Spraegel states that unburnt chalk has the same effect as if burnt, only in less degree. The process is more tedious, but the larger quantity of chalk which is applicable at the same expense would probably compensate for the slowness of its action. If your land be already calcareous use burnt chalk; if it do not contain lime use unburnt in large quantity. If your land is sour from wetness, the only remedy is drainage.

Dairy Management, &c.—*A Leicestershire Man.*—Confining cows entirely to the house tends to weaken their constitution, and renders them liable to disease. The same quantity of food given under these circumstances will increase the growth of fat, but will not diminish the yield of milk. Such a diminished quantity should be given as will keep them in the same condition as they were in when feeding in the fields. Selling cows is a practice more suited to arable lands than to permanent pasture. The cheapest way of burning clay is, not in kilns, but in large heaps, as is done on the railways. See answers on this subject above.

Diarrhœa.—*A New Subscriber.*—Your statement is very curious. Give us full particulars, and describe cases, and we will lay the matter before a competent person.

Dibbling Turnips.—*Don Quix.*—We never knew an instance of the seed being dibbled. Your distance ought to be at least 18 inches. Don't know what price per acre should be given. Watch a boy at work at it for half an hour, and calculate the price per acre from what he does.

Disease amongst Young Stock.—*J. L.*—Next week.

Drainage.—*J. Cl.*—We shall notice your work as soon as possible. We propose taking up the general subject shortly.

Farmers' Capital.—*Constant Reader.*—Your request has been forwarded to Mr. Morton.

Fences.—*W. W.*—Holly will effect your purpose, but it takes a long while to grow. Furze will do, but you must keep it down, or it will spread. It is a good plan to have a close cut Quick fence round the wood, and to make it ornamental by planting Laurels, Broom, Furze, &c., irregularly a perch or two wide in the field side of the hedge.

Garlic.—*E. S. W.*—You must dig each root out; or, if there is much of it, break up the Grass, fallow it well, and lay it down again.

Guano.—*Gorsyn.*—Hoe it in between the drills of Wheat some time this month; 2 to 3 cwt. per acre is the usual quantity. English oilcakes weigh about 3 lbs. a piece.

Haymaking Machine.—*A Sussex Subscriber.*—That invented by Salmon, of Woburn, and improved by Wedlake, of Hornchurch.

Laying down Grass-land.—*Novice.*—We hardly know how to improve on your plan. Your land being near the salt-water, needs no muriate of soda. Apply guano rather. If you lay your Grass-seeds down with a crop of Corn, should it turn out wet weather, a heavy crop of Straw would spoil the Grass.

Liquid Manure.—*A. H.*—Add sulphuric acid till effervescence ceases. Any of the soluble salts commonly used in manures would, each under special circumstances, strengthen the fertilising power of the liquid. Which of them, or how many of them, it would be advisable for you to use, depends on the condition of the land. Try a patch of land with 1 cwt. per acre of common salt in the liquid. The burnt earth you speak of may be of use as a top-dressing for Grass, especially if the land be a stiff clay.

Mangold Wurtzel.—*G. P.*—Field-beet is, perhaps, a better name.

Manure.—*A Cheshire Farmer.*—Apply about 2 cwt. of guano, broadcast, over the Wheat-land as soon as it is dry, and harrow or hoe it in.—*J. White.*—Six or eight bushels of bones per acre, previously treated with sulphuric acid. Guano is the best of the new manures: it is generally applied at the rate of 3 cwt. per acre. You should depend for your Corn crop, not upon a special application of manure to it, but upon the fertility of the land consequent upon your manuring and cultivation of the previous green crop.—*Delta.*—Phosphate of ammonia is a powerful but expensive manure. With regard to Potatoe-planting—hereafter. We do not know the patent inorganic manures you speak of. It is the interest of the farmer to pay little attention to *patent* manures, and to see to the due economising and preparation of the dung of his own farm-yard. We should be sorry to say, "Don't believe half the statements purporting to be of facts, put forth by the advertisers of their patent manures;" but we may safely say, "Don't admit half the inferences they would have you draw from these statements."

Marl.—*A Subscriber.*—This will not injure dung that it is mixed with. A source of carbonic acid will not volatilise ammonia. Marl does well applied as a top-dressing.

Nitrate of Soda.—*Cler., Lancast.*—Apply it now, in wet weather, 1 to 2 cwt. per acre.

One-horse Carts.—*M. C.*—You can get working drawings from any Scotch implement-maker, and get them made at any English implement maker. We do not advertise tradesmen in our Notices to Correspondents.

Parsnip.—*Leeds.*—Next week.

Road-material.—*V.*—If your clay is calcareous, it will not do to burn for road-material. Further particulars next week.

Rotation or Crops.—*T. Ridge.*—Your plan is a good one. Guano, or Potter's guano, is our best manure. Bone-dust and sulphuric acid might answer on your clay-land. Further particulars next week.

Sparrows.—*A New Subscriber.*—Put a little bird lime, some dry day, about the holes in your roof.

As usual, a host of letters has arrived too late for answers this week.

Markets.

SMITHFIELD, Monday, March 4.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	4s 0 to 4s 4	Best Downs & Half-breds	4s 2 to 4s 6
Best Short Horns	3 8 4 0	Best Longwools	3 0 4 2
Second quality Beasts	3 2 3 8	Ewes and second quality	2 4 3 8
Calves	4 0 5 0	Pigs	3 4 4 4

Beasts, 2115; Sheep, 22,810; Calves, 50; Pigs, 338.

The continuous heavy rain we have this day experienced has checked the advance in prices which, doubtless, would otherwise have been realised, in consequence of the very short supply. Notwithstanding the thorough wet day kept away many buyers, yet the unusual shortness of numbers caused a ready sale at rather more money than last week. The best Scots, for the most part, made 4*s* 4*d* per 8 lbs, and the best Short horns from Norfolk, 4*s*; those from Lincolnshire were few, and of indifferent quality, and cannot be quoted at more than 4*s* 2*d* per 8 lbs. The larger Downs and Half-breds have been more in demand, and made fully 4*d* per 8 lbs. more than of late; but the smaller Downs scarcely exceed our former quotations.—In some instances, perhaps, 4*s* 6*d* has been realised, but 4*s* 6*d* is the more general price. Ewes are a heavy sale—so many being in lamb at this time of year, the Butchers are very shy of purchasing them. Veal and Pork remain steady.

Friday, March 8.

We have to-day a very large increase on last week's number of Beasts, owing to the arrival of some Scotch vessels with an extra quantity for Smithfield. We notice, also, a few from Holland, in very good condition. Our Monday's highest quotations can hardly be supported; the best qualities of Beef cannot be quoted at more than 4*s* 2*d* per 8 lbs., and other qualities in like proportion. Sheep trade is brisk, at Monday's prices; there are a few more, but all in demand. Calves and Pigs sold slowly, at late rates.

Beasts, 919; Sheep, 8400; Calves, 109; Pigs, 200.

J. W. 41, West Smithfield.

ENGLISH TIMBER AND BARK.—March 5, 1844.

Round Timber, per load.		Plank, per foot cube.		Inch board, p. ft. sup.

Beech	3 10 5 0	1 6	2 0	2½

Oak Bark (per load), 18*l.* to 19*l.* 10*s.*

J. B.

WOOL.—British, Friday, March 8.

During the past week the Market has been flat, and lower rates have been submitted to. The report of the Bristol West Fair by that last Mails business was done, and that at reduced prices.

	per lb.			per lb.
Long-woolled Wethers	1*s* 1*d* to 1*s* 2*d*	Southdown Wethers	1*s* 1 to 1*s* 2	
Do. Hoggetts	1 1 1 2½	Kent Fleeces	1 2 1 3	
Southdown Fleeces	1 0½ 1 2			

James Parson, Wool Broker.

Mark Lane, Friday, March 8.—The arrivals of all descriptions of Corn have been moderate during the week, and the few parcels of English Wheat fresh up for this morning's market realised fully Monday's prices. Business in free Foreign has been very limited, but we observe no depreciation in its value, with the exception of a cargo of Polish Odessa from Trieste, sold ex ship at 38*s.* per qr. in Bond. We have not heard of any transactions under lock or key. Having therefore a slow sale at our quotations.—Beans and Peas are unaltered in value.—The Oat trade is heavy, and rather lower.

Kingsford and Lay.

COVENT GARDEN, Mar. 8.—The supplies of most articles during the week have been pretty well kept up, and trade begins to get brisk. No alteration has taken place in the prices of Pine Apples since our last report; Grapes are a little advanced in price, they are offered at from 1*s.* to 4*s.* per lb. Large Kitchen Apples are becoming scarce, and are offered at higher prices. Good Dessert Pears are not plentiful; they are selling at from 4*s* to 12*s.* per bushel. Oranges are sufficient for the demand. Lemons are offered at nearly the same prices as quoted in our last report. Chesnuts are good and plentiful. A few Strawberries are still in the market, but they are only brought in small quantities. The supply of most kinds of Vegetables has been tolerably well kept up. Large White or Cornish Broccoli is selling at from 8*d.* to 12*s.* per dozen heads. Savoys have not been very plentiful during the week. Little variation has taken place in the prices of Brussels Sprouts or Greens, which continue to be pretty abundantly supplied. Carrots and Turnips are good and plentiful. Seakale is a little advanced in price since our last report. French Beans are nearly the same as last week. Asparagus and Rhubarb are good and plentiful. Celery is becoming scarcer. Cucumbers being more plentifully supplied are becoming cheaper; they are offered at from 2*s.* to 4*s.* each. Cut Flowers chiefly consist of Gardenia radicans and florida, Erica Willmoreana, Lechenaulia tricolor, Camellias, Scarlet Pelargoniums, Lily of the Valley, Acacias, Azaleas, Heliotropes, Tulips, Jonquils, Cinerarias, Moss, Province and China Roses.

Fruits.

Pine Apple, per lb., 6*s* to 10*s*	Almonds, per peck, 6*s* to 7*s*
Grapes, Portugal, per lb. 1*s* to 3*s* 6*d*	Sweet Almonds, per lb., 3*s* 6*d* to 6*s*
Apples, des., p bush. 4*s* to 12*s*	Nuts, Spanish, per bushel, 10*s*
—— Kitchen, p bus. 8*s* 6*d* to 8*s*	—— Brazil, 16*s*
Pears, per half-sieve, 4*s* to 12*s*	—— Hazel, 2*s* to 4*s*
Oranges, per dozen, 2*d* to 3*s*	—— Barcelona, 20*s* to 22*s*
—— per 100, 5*s* to 16*s*	—— Cob, per 100 lbs., 90*s* to 100*s*
Lemons, per doz. 1*s* to 3*s*	Chesnuts, per peck, 2*s* to 6*s*

	Scorzonera, per bundle, 1*s* to 1*s* 6*d*

POTATOES.—Southwark Waterside, March 4.

There has been considerable firmness in the prices during the past week, and the best samples have gone off readily; other qualities, also, have been in more request. We have had but a limited supply, generally, particularly from the northern districts, owing to a severe snow storm, which has caused a slight advance in the price of the best samples; yet this has been occasioned more by the shortness of the supply, than by any extra demand.

Trade very dull. Joshua Banks, Hay Salesman.

THE CONICAL HOT-WATER BOILERS, invented by J. Bowman, Esq., and constructed at any site from JOHN WEEKS, Horticultural Architect, &c., of Gloucester-place, Chelsea, London.

J. Bowman having had every opportunity afforded him by an extensive practice to bring this apparatus to perfection, begs to offer it to the public confidently and economically; it may be seen at Messrs. Chandler & Sons' Nursery, Vauxhall; Messrs. Loddiges', Hackney; Messrs. Henderson's, Pine Apple-place; Messrs. Veitch and Son's, Exeter; Mr. Penny's, Plymouth; the Royal Botanical Society's Gardens, Regent's Park; and at the Gardens of the Horticultural Society of London. Considerable improvements have been effected since last season; particulars of which are in course of preparation.

HORTICULTURAL BUILDING & HEATING by HOT WATER.

J. WEEKS & Co., ARCHITECTS, &c., Gloucester-place, King's-road, Chelsea, Hothouse-Builders, and Hot-water Apparatus Manufacturers, beg leave to inform the Nobility and Gentry, that their business, which has been extensive throughout the country for many years, is entirely confined to the BUILDING OF HORTICULTURAL ERECTIONS of every description, and the HEATING of them by HOT WATER.

CONICAL and other BOILERS of all sizes; their largest consumes but a small quantity of fuel, only requiring attention once in 10 hours, and will heat a range of Forcing-houses 300 feet in length.

Their improved plan of BOTTOM-HEAT FOR PITS, by means of an open trough under the bed, is now being universally adopted.

References may be had, and their works seen at most of the Nobility and Gentlemen's seats in the country, nearly the whole of the London Nurseries, and a great variety of Horticultural Erections and Hot-water Apparatus, Models, Plans, Estimates, &c., at their Horticultural Manufactory, Gloucester-place, Chelsea, near Sloane-square.

WIRE-WORK, HOT-WATER APPARATUS, GREENHOUSES, &c.

ST. THOMAS BAKER, MANOR-HOUSE, MANOR-PLACE, KING'S-ROAD, CHELSEA, Manufacturer of INVISIBLE WIRE FENCE, to resist Grazing Stock, and rendered Rabbit-proof. WIRE-WORK in Trainers, Arches for Walks, Bordering, Flower-stands, Pheasantries, &c. HORTICULTURAL BUILDINGS, Green and Hothouses, Conservatories, &c. The same heated by HOT-WATER APPARATUS, on improved and economical principles.

Parties waited on in Town or Country, and Drawings and Estimates free. Work for the Trade as usual.

Ward's Cases, or Domestic Greenhouses.

BURBIDGE AND HEALY beg respectfully to inform the Horticultural world that they are quite ready to supply their new BOILER, of every size. They have now fixed a sufficient number to warrant them in stating that what they put forth as the qualities of their Boiler and Furnace arrangement may be perfectly relied upon: they have put up one at the Horticultural Gardens, where B. and H. believe it is considered to answer as represented; they have also fixed it in connection with a new description of Iron Tank, which combines the qualities of the round pipe and the open tank, which may be pronounced the perfection of a Heating Apparatus for Horticultural purposes, particularly for Graperies, Epiphyte-houses, Melonpits, &c., &c. The arrangement is such that any gentleman or gardener may have the whole constructed so as to be put together with the greatest facility by the gardener, first sending a correct plan to 130, Fleet-street. A Prospectus may be had detailing the prices, &c.

RENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance, can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of Iron will be found cheaper than of any other material. MR. RENDLE, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing a more rapid vegetation in Plants than any substance known. It may be had at Mr. Lawes' Factory, Deptford Creek, price 7s. per cwt.

Phosphate of Potash, 14s. per cwt.		
,,	Soda .	12s. ,,
,,	Magnesia 9s.	,,
,,	Ammonia 1s. per lb.	

MANURES FOR WHEAT, &c.

POTTER'S GUANO.—Result of an Experiment on Wheat, tried near Colchester—sown Nov. 1842, reaped August 1843. POTTER'S GUANO.—Seven bushels per acre gave 54½ bush. Grain. Daniell's Manure, 40 bush. per acre, gave 46 bush. Grain. Difference in favour of POTTER'S GUANO, 8½ bush.

Note.—The Daniell's Manure cost 3l. POTTER'S (present price) 2l.—Works 28, Upper Fore-street, Lambeth; sold by M. FOTHERGILL, 40, Upper Thames-street.

BEAUTIFUL FLOWERS. — POTTER'S CONCENTRATED LIQUID GUANO, for Flowers, Kitchen Garden Produce, &c. Sold by appointment, by SAVORY and MOORE, Chemists to the Queen, 136, New Bond-street, and 220, Regent-street, and can be had of most respectable Chemists and Seedsmen. Price 3s. 6d. the quart bottle, with directions.

DR. LINDLEY, in the *Gardeners' Chronicle* for 1843, p. 560, says—"POTTER'S GUANO will convert your desert into a paradise." And in the Number, Feb. 10, 1844—"POTTER'S GUANO is unrivalled."—Works, 28, Upper Fore-street, Lambeth.

GENUINE PERUVIAN & BOLIVIAN GUANO ON SALE, BY THE IMPORTERS, ANTONY GIBBS AND SONS, LONDON; GIBBS, BRIGHT, AND CO., LIVERPOOL AND BRISTOL. 47, Lime-st., Mar. 8, 1844.

ON SALE, in any quantity, PERUVIAN and BOLIVIAN GUANO, genuine as imported.—Apply to COTESWORTH, POWELL, and PRYOR, London; EDWARDS, DAWSON, and CO., Liverpool; or WILLIAM J. MYERS and Co., Liverpool, the Importers.

GUANO, PERUVIAN, &c.—The above Manures, also Potter's Guano, Nitrates of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.

Lists of Prices, with Synopsis of mode of use, on applications to MARK FOTHERGILL, 40, Upper Thames-street, and 5, Railway Place, Mark-lane, London.

PERUVIAN GUANO, of first quality, and in any quantity, direct from the Bonded Stores. Also African Guano, and Nitrate of Soda.—Apply to H. ROUNTHWAITE and Co., 6, Cable-street, St. George's Crescent, Liverpool.

CHOICE FLOWERS AND PLANTS IN POTS.

HUMPHREYS'S COMPOUND, applicable to all Greenhouse Plants, to Hyacinths and other Bulbs, and to promote the germination of Seeds. Sold in bottles 1s. 9d. each, by FLANAGAN and SON, Mansion-house-street; WARNER and WARNER, Cornhill; HURST and MCMULLEN, Leadenhall-street; W. CLARK, Bishopsgate-within; SMITH, Islington Nursery; GRIMLEY and Co., Covent Garden; BATT and RUTLEY, 412, Strand; WILLIAM and JOHN NOBLE, Fleet-street; SMITH, Covent Garden; CHARLWOOD, Tavistock-row; W. J. NUTTING, 46, Cheapside; G. LAWRENCE, 18, Piccadilly; JOHN KERNAN, Great Russell-street, Covent Garden; LOCKHART, 155, Chespside; SHUTTLEWORTH, Pantheon; MINIER, ADAMS, and NASH, 69, Strand; THATCHER and SON, Islington; J. FRYER, Clarendon-terrace, Camberwell; THOMAS ANSELL, Camden Town; THOMAS WATKINSON, Market-place, Manchester; T. S. KING, Rochester; W. E. RENDLE, Plymouth; DICKSON and Co., Edinburgh; PONTEY, Leeds; FISHER, HOLMES, and Co., Sheffield; P. LAWSON and SON, Edinburgh; J. THORNE, Shepton Mallet; and other leading SPECIMENS in town and country. Wholesale Agents, DAVY, MACKMURDO, and Co., 100, Upper-Thames street, London.

THE URATE of the LONDON MANURE COMPANY, 5l. per Ton. It is with the greatest satisfaction, after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By promoting a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops. The Urate may be sown broadcast, or which is preferable, by the drill, at the rate of one ton to three acres, and it is desirable it should not be placed more than two inches below the surface. As a top-dressing for Wheat the Urate has been used with great advantage. Gardeners and Florists will find it very useful for Dahlias and other roots. Full particulars and Testimonials will be forwarded on application. Genuine Peruvian Guano; Phosphate and Sulphate of Ammonia; Gypsum and every other artificial Manure.

EDWARD PURSER, Secretary, 40, New Bridge Street.

THE NEW MANURE.

HUMPHREYS'S FARMERS' COMPOUND, presenting superior advantages to any Manure yet offered to the Public. It is rich in the Phosphates, Silicates, and Nitrogen, with certain new agents, so as to prove most economical and effective for Wheat, Barley, Pulse, Potators, Meadow Land, &c. Being manufactured on a new principle, this Manure *will not wash out of the soil* like Guano or the Salts, but with the mild and lasting qualities of the "Homo-made" combines the most energetic fertilising chemical agents; adapted to all the purposes of Husbandry and Garden Culture, and unrivalled as a Top-DRESSING for all Spring Crops. Quantities per acre, according to the condition of the land:—For WHEAT, from 2 to 5 cwt.; GRASS, CLOVER, &c., from 1 to 4 cwt; TURNIPS, from 2 to 4 cwt.; HOPS, from 4 to 6 cwt. 12s. per cwt.—Wholesale Agents, DAVY, MACKMURDO, & Co., 100, Upper Thames-street, London.

GLASS SUPERSEDED for HORTICULTURAL PURPOSES by WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, rendering Muslin, Calico, or Linen, for the Frames of Greenhouses, Pine, Melon, or Cucumber Stoves, &c., impervious to rain or moisture, admitting light equal to Glass, much warmer, and the plants never burn under it.

Noblemen, Gentlemen, and Gardeners will, by using this composition, have the only effectual protection for their Fruit-trees during the blooming season; it is a certain defence from frost, sleet, wind, and blight; its transparency admits the general beams of the sun, with abundance of light, which causes the bloom to expand with increased luxuriance, the fruit to set and swell more freely, much earlier, and a crop of fruit to any extent may be warranted. The covering not to be moved by day (except to thin the Fruit, which will be necessary), till the month of June. It is recommended that the Calico be prepared early, so as to be thoroughly dry before using.

Sold in Bottles, with directions for use, pints, 2s. 6d., quarts, 4s. 6d. each. One pint is sufficient to coat four Frames twice over, each Frame to be 5ft. by 3ft. 3in., or thereabouts. Prepared by GEORGE WHITNEY, Chemist, Shrewsbury. Seedsmen, Florists, and Merchants supplied by Mr. W. BAILEY, Chemist, North-street, Wolverhampton. Appointed Agents:—Messrs. BUTLER and MUCKLEY, Covent Garden, where a sample of prepared calico may be seen; Mr. WATKINSON, Market-place, Manchester; PAGE and SON, Southampton; T. and C. WHALLEY, Nurserymen, Liverpool.

Agents wanted for London and the country.

ASPHALTUM in its pure state, with all the material and instruction how to prepare, or if required, the labour performed at a moderate charge.—Apply to J. A. HUSSARD and SON, 20, Harp-lane, Tower-street. All Letters prepaid.

KEENE'S PATENT MARBLE CEMENT.—This CEMENT is particularly adapted for the Walls and Floors of Conservatories and Greenhouses, being calculated, from its extreme hardness, to resist the wear incident to ordinary Plastering. For Floors it has a threefold advantage over Stone-paving: 1st, in its lightness; one inch in thickness of KEENE'S CEMENT sufficing where 2 to 3 inch flagging would be employed. Next, in its appearance, combining as it does the hardness of stone with an uniform colour and even surface free from joints; and lastly, in economy, being one-third the price of Portland paving.

The most conclusive evidence can be given of the utility of KEENE'S CEMENT for these purposes by the Patentees and Manufacturers,—JOHN BAILEY WHITE & SONS, Millbank-st., Westminster.

TO AGRICULTURISTS.

THE Dry Material for making CAMPBELL'S CORN-PRODUCING LIQUID, or FERTILISING STEEPS, which have arrested the attention of Agriculturists in all parts of the United Kingdom, is now to be had in Boxes containing quantities for 5 Gallons and upwards, at the following prices, viz.:—

For WHEAT, Material per Gallon	2s. 6d.
,, OATS and GRASSES, ...	1 6
,, BARLEY, ...	2 0
,, BEANS and PEASE, ...	2 6
,, TURNIPS and RAPE SEED	2 6

Agents in London:—Mr. EDWARD PURSER, 40, New Bridge-st.; Messrs. GEO. GIBBS and Co., 26, Down-st., Piccadilly; and Messrs. THOMAS GIBBS and Co., Corner of Half-moon-street, Piccadilly.

SUPERIOR SUBSTITUTE FOR TARPAULIN, &c.

C. MACINTOSH & Co., having made a considerable reduction in the price of the Patent India Rubber Covers for Carts, Waggons, Ricks, &c., beg to call the attention of Users of Tarpaulin and Oiled Sheets to the superiority of their manufacture as an effectual protection against wet, not liable to crack on being folded, and more economical than any other Waterproof Cover.—22, York-street, Manchester; and 46, Cheapside, London.

GREAT ECONOMY.—*Much time and a great deal* of labour will be saved by the use of the SUSSEX CHURN. ATTWOOD, WIMBLE, and WARNER, Manufacturers, Lewes. This Churn being made entirely of block tin, the necessary degree of temperature can be given to the cream, by placing it in a pan of cold or hot water, which ensures the butter coming in 10 or 12 minutes at all seasons of the year. The simplicity of its construction, and the facility with which it may be cleaned, are no inconsiderable advantages over those now in common use.

Sizes.	Nos. 00.	0.	1.	2.	3.
Churn	2½ lbs.	4 lbs.	7 lbs.	14 lbs.	28 lbs. of butter.
Price with pans complete,	18s.	20s.	28s.	33s.	40s.

Delivered, carriage paid, to any part of London.

London Agents.—BENHAM, 19, Wigmore-street, Cavendish-square; LIVERMORE, 30, Oxford-street; BAILY, 71, Gracechurch-street; WRIGHT'S Range Warehouse, near the Monument.

Export Agent.—BARNES & Co., 109, Fenchurch street.

N.B.—To be seen at the Polytechnic, and Adelaide Gallery.

Observe.—The Improved Water Pail, 4s. and 5s. each.

A SINGLE BOTTLE OF BETTS'S PATENT BRANDY may now be obtained in a perfectly genuine state. This convenient arrangement for both vendor and purchaser, and their mutual security against deception, is effected by the use of BETTS'S PATENT METALLIC CAPSULE, made of pure and SOLID METAL, (not Tin Foil) which completely encloses the cork and mouth of the bottle, and is embossed with the words "BETTS'S PATENT BRANDY, 7, SMITHFIELD BARS," the *fac-simile* of which is engraved on a label affixed to each bottle.

In the present day it is impossible to produce anything new and useful without exciting the cupidity of imitators. Already attempts are made to mystify the identity of the original and genuine article, by trusting upon the public the contents of bottles having a Tin Foil covering, falsely denominated "a neat metallic capsule." J. T. BETTS & Co. therefore deem it essential to impress upon purchasers the absolute necessity of comparing the embossed Capsules with the Labels, as an infallible mode of detecting fraudulent substitutions.

BETTS'S PATENT BRANDY, thus protected, may be obtained of the undermentioned Wine and Spirit Merchants, at 9s. 6d. per Bottle, Bottles included, or at 10s. per Gallon, as heretofore, at

GARNER'S STAFFORDSHIRE—Just Published,

THE NATURAL HISTORY, ANTIQUITIES, MANUFACTURES, &c., of the County of Stafford. By ROBERT GARNER, F.L.S., 8vo., with many Illustrations. Price One Guinea. JOHN VAN VOORST, 1, Paternoster-row.

In fcap. 8vo., with Illustrative Diagrams, price 9s.,

ANATOMICAL MANIPULATION; or, the Method of Pursuing Practical Investigations in Comparative Anatomy and Physiology. Also an Introduction to the Use of the Microscope, &c., and an Appendix. By ALFRED TULK, M.R.C.S. M.M.S., and ARTHUR HEPFREY, A.L.S. M.Mic.S. JOHN VAN VOORST, 1, Paternoster-row.

BEE HIVE.—THE BEE AND FRAME HIVE.

Early in April will be published, by Mr. JOHN VAN VOORST, of Paternoster row, in the Horticultural Establishment, for the convenience of transmission through the Post Office,

A DESCRIPTION of the BEE and FRAME BEE-HIVE, invented by T. W. [illegible], Esq., with some short Directions for the Management of an Apiary.

A Bee and Frame Hive may be seen at Mr. JOHN MEEKIN'S, No 10 Great Marylebone street, London.

SECOND EDITION

MILLS'S TREATISE ON THE CULTURE OF THE CUCUMBER, MELON, SEA KALE, AND ASPARAGUS. Published by WILLIAM SMITH, 113, Fleet street

The truth of Dr. LINDLEY'S statement in his review of the above work was strictly verified at the late Great Exhibition of Cucumbers at Ipswich, viz., "Any person having Mills's book, whether a gardener or not, can grow Cucumbers"

By the report of the above exhibition to the *Gardeners' Chronicle* the first prize was won by an almost one, Edward Leather, Esq., on Mills's system

THE LANCET, greatly Enlarged, and the price changed from THREEPENCE to SIXPENCE. *Stamped* for free postage

Mr WAKLEY, Surgeon, M.P., EDITOR,
HENRY BENNET, M.D., Sub Editor

LIEBIG (Giessen)—Lectures on Chemistry. Applicable to Animal and Vegetable Physiology, Health, Diet, Disease, Agriculture

LISTON (London)—Lectures on all the Operations of Surgery

SCHONLEIN (Berlin)—Lectures on Clinical Medicine

BAILLARGER (Paris)—Lectures on Diseases of the Brain and Insanity

At the conclusion of the current volume of THE LANCET, 16th March, 1844, that Journal will be PERMANENTLY ENLARGED more than one THIRD beyond its present size, and *Stamped* for universal delivery by *Post*. The future price of the Journal will be *eightpence* instead of *eightpence* the Number, thus at the same time *adding* to the size of the Work *more than a third* and *reducing the charge one fourth*—events, probably, which are unprecedented in the history of any useful periodical literature. Nothing but the now certain enormous increase of the sale and circulation of the Work could justify the presentation of these advantages to its readers

THE ENLARGED LANCET

will commence with the celebrated Lectures on CHEMISTRY, as that science is applicable to Medicine, Animal and Vegetable Physiology, Diet, Health, the Cure of Disease and scientific Agriculture delivered at Giessen, by the renowned PROFESSOR LIEBIG. These invaluable Lectures have been expressly composed for publication in England, and are furnished to THE LANCET by PROFESSOR LIEBIG HIMSELF.

A complete course of Lectures on all the OPERATIONS OF SURGERY, delivered by the distinguished PROFESSOR LISTON, who, as an operative surgeon stands without an equal in Europe.

A course of Lectures on CLINICAL MEDICINE, delivered at the GREAT CHARITY HOSPITAL, Berlin by PROFESSOR SCHONLEIN, first Physician to the King of Prussia

A course of Lectures on those DISEASES of the BRAIN which produce Insanity, delivered in Paris by M. BAILLARGER, Physician to the gigantic HOPITAL DE LA SALPETRIERE, an Institution which contains 1500 insane persons. These Lectures will embrace the whole subject of Mental Diseases

In addition to the above Lectures, some of which, in point of value, will be unsurpassed by productions of a like character in any language, the ENLARGED SIZE OF THE LANCET will furnish it with space for containing:—ORIGINAL COMMUNICATIONS,—ample REVIEWS of Medical Works; Reports of DISCUSSIONS IN MEDICAL SOCIETIES; CRITICAL ANALYSES of the original Communications published in the other British Medical Journals, Analyses, and Reports of Papers devoted to Chemistry and Pharmacy.—TRANSLATIONS from the Foreign Journals. REPORTS of the most interesting Cases and Operations in all the great Hospitals of London

Reports of all Public MEETINGS of the PROFESSION, and of the Speeches on Medical Law delivered in PARLIAMENT; all the general Medical Regulations of the POOR LAW UNIONS;—ARMY AND NAVY Medical Intelligence;—Medical Appointments, and Medical News of every description, occurring in all parts of the civilized world

THE LANCET, which has long maintained the largest sale and circulation of any medical Journal in the kingdom, will now be printed in a form to admit of its general transmission by post, at the cost of A PENNY STAMP. Mr Church fully expects that orders for the Work, to this date including the *stamped* or the *unstamped* Numbers, will be given to Booksellers or News men without delay

London: The Lancet office, 18 Princes street Cavendish square

THE IRISH FARMERS' GAZETTE and HORTICULTURAL JOURNAL. Edited by LAWRENCE MEREDYTH, A.B., T.C.D. Landscape Gardener and Improver of Estates &c

This Paper was commenced in May 1843 and having been adapted to the circumstances of Irish Farmers, is now in a transition state from the worst to the best system—it daily points out the best practice, but gives no rules how every operation should be performed, nor recommends the ORGAN OF AGRICULTURAL IMPROVEMENT IN IRELAND where the advantages which have already resulted from it are universally recognised. The result of practical communications and experiments on all subjects connected with the improvement of land and the increase of its produce, are freely communicated to the Editor and records. Selections of the most practically useful articles are made from the various works on farming with which the press now teems, and utterly exclusion rejection—as none, the bane of the Irish Farmer and devoting its columns exclusively to Agricultural and Horticultural improvement

THE FARMERS GAZETTE has the distinguished honour to be strongly supported by the approbation of the eminent individuals, Wm Blacker, Esq., James Smith, Esq. of Deanston and the late Mr Tuke, and is received with such confidence that the practice of having its contents read at stated periods to assembled farmers is becoming general. The circulation of the IRISH FARMERS GAZETTE has of late been extending even in England and Scotland, where, up to this period no effort has been made to bring it under notice, but where the principles of good husbandry (by every where the same, it is calculated to be equally useful as it has been found to be in Ireland. The most practically useful essays on Farming are from time to time, struck off for distribution in the shape of TRACTS FOR FARMERS, and have been very extensively circulated, viz:—On the Dairy—A Catechism of Thorough Draining and Subsoiling—The Culture of Flax—Management of Manure and Green-Cropping and House Feeding, are nearly ready. Also, on the 1st Jan. was published, the 'Irish Farmers', Gardeners', and Foresters' Almanac"

THE IRISH FARMERS' GAZETTE is published every Friday, at 23, Bachelor's Walk, Dublin, and goes free by post. Annual subscription, 10s., half-yearly, 5s., payable in advance; and orders directed to the publisher are immediately attended to.

THE LATE Mr. LOUDON.—The following Subscribers to the Works of the late Mr. Loudon have been obtained since making up the List which appeared in the *Gardeners' Chronicle & Agricultural Gazette*

ARBORETUM BRITANNICUM.—10*l*.

GARDENERS' BENEVOLENT INSTITUTION.—Notice is hereby given, that an Election for three Pensioners on the Funds of this Charity will take place in June next. All persons desirous of becoming Candidates, are requested to forward their testimonials and certificates to the Secretary on or before the 26th inst. (after which time they will not be received), and of whom printed forms of application may be had.

By Order, Edwd. R. Cutler, Secretary, 97, Farringdon-st.

ENTOMOLOGICAL SOCIETY OF LONDON.—PRIZE ESSAYS.—A Prize of 5*l.* has been offered by the Rev. F. W. Hope, F.R.S., for the best Essay on the Natural History, Habits, and Peculiar Properties of VESICATORY INSECTS, with reference chiefly to their practical utility, an account of all species hitherto employed as Vesicants, their relative value in respect to the quantity of Cantharidin they contain, and notices of the Monographs and other Works in which their properties are described. The Essays to be delivered at the Society's Rooms, 170, Old Bond-street, London, addressed to the President, with a sealed letter and motto, on or before the 2d Dec., 1844. A second Prize of 5*l.* has also been offered by the Rev. F. W. Hope, for the best Memoir on the Natural History of STYLOPS, to be drawn up from personal observation, with especial reference to the distinction of the sexes, mode of propagation, and early states of the insects of that genus. TRANSACTIONS. A new Part, completing the Third Volume, with Plates, Indexes, &c. Price 6*s.* 6*d.* PROCEEDINGS, Part V., and the last ANNIVERSARY ADDRESS, delivered by the President, are also ready for delivery. London: Longman and Co.; and Baillière.

GRAND CARNATION and PICOTEE SHOW, at the COPPICE, near NOTTINGHAM, on Tuesday, August 6, 1844, open to all England.—Two Silver Cups, value Five Guineas each, will be presented by I. F. Wood, Nurseryman and Florist; one for the best stand of 10 dissimilar Carnations, consisting of two Scarlet Bizarres, two Crimson Bizarres, two Scarlet Flakes, two Purple Flakes, and two Rose Flakes. Also, one for the best stand of 10 dissimilar Picotees—two Heavy and two Light-edged Red, two Heavy and two Light-edged Purple, and one Heavy and one Light-edged Rose.

Conditions of Exhibition.—1. Entrance, 5*s.* to each Cup, which sums will be apportioned by the committee in numerous other prizes; also a certain sum will be given for the best seedling in each class. 2. No seedlings to be exhibited in any pans for the cups. 3. The Flowers to be staged by 12 o'clock in the forenoon—none admitted after that period. 4. All Flowers must be *bond fide* the growing and property of each Exhibitor for two months previous to the day of show, and bloomed in his own garden. Each Exhibitor must sign a declaration to this effect, previous to staging. 5. All Flowers exhibited must be labelled and properly named. 6. The Subscriptions to each Cup must be paid, either in cash or post order, to Mr. G. I. Robinson, Office, 4, Ram Inn Yard, Long Row, Nottingham, Honorary Secretary to the Committee, on or before the last day of April next.

EUCHARIDIUM GRANDIFLORUM—A SPLENDID NEW HARDY ANNUAL.

WILLIAM MAY begs to offer the above new and beautiful Annual for the first time, seeds of which were kindly presented to him in 1842 by Capt. Widdrington, R.N., who introduced it from the Royal Botanic Garden of St. Petersburg. It is twice the size of E. concinnum, of a brilliant dark rosy red, and very appropriate for masses or beds, blooming most part of the summer, and is decidedly one of the best of annuals in cultivation. May be had in packets, at 2*s.* 6*d.* each, Post-paid.

William May, Hope Nursery, Leeming-lane, Bedale, Yorkshire.

SEEDLING VERBENAS.

E. H. FULLER respectfully informs the Public that he intends sending out in April the following new and distinct Varieties of VERBENAS, which have been universally admired, and submitted to Dr. Lindley.—Vide *Gardeners' Chronicle*, Oct. 14, 1843, page 721.

E. H. Fuller, No. 2, (Incomparable), "brilliant rich purple, with a white eye, the best of its colour we have seen."—Plants in April, 5*s.* each.

No. 3, Lucasii, "delicate pink, clear and good."—2*s.* 6*d.* each.

No. 4, Louis-Philippe, rosy-purple, clear and steady in colour, a good Variety."—Plants 2*s.* 6*d.* each.

"These flowers are characterised by having the colours very clean, not dirty nor uncertain, as it frequently happens. The flowers are rather small, but this may arise from want of better cultivation."

The usual trade allowance if three or more Plants are ordered. All Orders will be sent post-free, or by coach, paid to London. A Catalogue of Fuchsias, Geraniums, &c., &c., will be forwarded by post on application.—Worthing, March 14, 1844.

FLORIST TO HER MAJESTY THE QUEEN.

"PETUNIA PUNCTATA."

WILLIAM MILLER, in bringing this extraordinary and beautiful production into public notice, does so without the slightest diffidence, being fully assured of its giving the most entire satisfaction. It is of a dwarf habit, and dark green foliage. The reason it was not exhibited at the London Shows was its not flowering till October. It has been submitted three times to Dr. Lindley, whose opinion will be found as follows (pages 721, 774, 777)—"M. R.: Your Seedling, No. 25, is quite a novelty; it is a beautiful, distinct, and desirable variety; the colour is a soft, decided blue, mottled with white, and spotted with Rose; these gradually disappear, and leave the flower a beautiful blue mottled with white; in this state the flower dies; it will be an acceptable addition to this beautiful class."

Plants have already been ordered for the Queen's Garden, Claremont; plants in April at 7*s.* 6*d.* each, including case and postage; the usual allowance to the Trade when three or more are taken at once.

W. M. has also two Splendid Seedling Verbenas.

"BLUE QUEEN," and "ZEUXES."

"Blue Queen," the best blue Verbena yet out (see Dr. Lindley's opinion in *Gardeners' Chronicle*, July 15, page 721)—"M. R.: Your Sweet scented Seedling, No. 105, is the best we have seen of its colour—bright blue Lilac; the flower is large, smooth, glossy, and perfectly free from crumples." Price per plant, 5*s.*

"Zeuxes," beautiful novel Rosy vermilion, with large light eye (see Dr. Lindley's opinion in *Gardeners' Chronicle*, September 30, page 681)—"*J. Miller:* Your Seedling named Zeuxes is large and very brilliant." Price per plant, 3*s.* 6*d.*; plants in April; the usual allowance when three or more are taken at once.

W. M. has plants of rich coloured scarlet Geranium, "Fire ball," now ready, at 5*s.* each, post free.

N.B.—The above new plants may also be had of the following Agents:—Warner and Warner, 28, Cornhill; Hurst and Mac-Mullen, Leadenhall-street; Noble and Sons, 132, Fleet-street; Flanagan and Sons, 9, Mansion-house-street; Kernan, Seedsman, Great Russell-street, Covent Garden; and Corsten, Seedsman, St. James's-street, Covent Garden.

Plants can be sent post free, or in pots, as requested. A remittance requested from unknown correspondents. Providence Nursery, Ramsgate, March 12th, 1844.

DILLISTONE'S APPLE, the STURMER PIPPIN.—From the satisfaction given last season by the mode of transmitting by post scions of the above most valuable Apple, to distant parts of England, Scotland, and Ireland, S. & J. Dillistone are again induced to offer it in packets (true from the original tree), post-free upon receipt of a Post-office order, payable at Halstead, for 3*s.* 6*d.*, or the amount in stamps.

The Editor of the *Gardeners' Chronicle*, in "Notices to Correspondents," Nov. 25, 1843, says—"The Sturmer Pippin deserves the character given of it."

Mr. Rivers, in the Supplement to his Fruit Catalogue, says—"The Sturmer Pippin again deserves noticing, for its excellent qualities; it seems to grow and bear well in all soils and situations, and will supply the desert or kitchen from March till July. It can be grafted with success till middle of May."

A choice Collection of Roses, Dahlias, Pansies, &c. &c. Nursery Stock in general.—Sturmer Nurseries, March 11, 1844.

DAHLIAS.

J. KEYNES, Florist, Salisbury.—"Standard of Perfection," (Keynes).—The finest self-coloured Dahlia in the World! gained the 1st class prizes at Stonehenge, Windsor, Kingston, Surrey Zoological Gardens, and Crown and Anchor, Stockwell; also the 1st prize specimen at Stonehenge Floricultural Society, Stockwell. "It is as round as any Dahlia in cultivation; as complete an unbroken circle as could be drawn with the compasses; and as globular in front as possible. It is symmetrical to a hair, and as double as a Ranunculus. It is so remarkable as to be instantly recognised among a thousand. Colour, deep crimson. It is the flower of the season, and must be had."—*Gardeners' Gazette*, Oct. 14. "The best-grown flower we ever saw, without exception, every requisite to meet the taste of a connoisseur being complied with; good colour, a honeycomb, regularity of growth and disposition in the leaves, and above all, as complete a rotundity of shape as if it had been cast in a mould."—*Salisbury Herald*, Sept. 2, 1843. Plants in May, 1844, 10*s.* 6*d.* "Orange Superb," (Dodd's) first-rate show-flower, 10*s.* 6*d.* "The specimen sent would grace any stand."—*Glenny.* "Emma Noke," (Dowding's) bluish white, extra fine, indispensable to a first-rate stand, 10*s.* 6*d.* Catalogues containing all the fine old varieties and new flowers for the season may be had on application. Salisbury, March 15, 1844.

WILLIAM MASTERS begs to call the attention of the Nobility, Gentry, &c., to his newly and well assorted COLLECTION OF GARDEN AND FLOWER SEEDS, which being principally grown under his immediate inspection, he can particularly recommend.

100 papers finest Annual Flower Seeds			24*s.* 0*d.*
50	do.	do.	12 6
25	do.	do.	6 6

[If the selection is left to W. M.]

RANUNCULUSES, ANEMONES, PELARGONIUMS, AURICULAS, CARNATIONS, AND LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by Appointment Florist to Her Majesty, begs to inform the Nobility, Gentry, and Amateurs, that, in consequence of the success he has had in the cultivation of the above flowers at his new Garden, he can offer them at very moderate prices. He would particularly recommend an early application to be made for RANUNCULUSES and ANEMONES, as they should not be planted later than the end of March to ensure a good bloom. His Catalogue of PELARGONIUMS, AURICULAS, and NEW PLANTS, is now ready, and will be forwarded by post on application. The Trade supplied.

SEEDLING FUCHSIAS.

W. PAWLEY, of the White Hart Hotel, Bromley, Kent, begs to inform the Nobility and Gentry that he has purchased the entire Stock of three splendid Fuchsias, which he intends sending out in April next, at 10*s.* 6*d.* per plant. They are considered by competent and practical men to be the best known, and twice the size of any yet in cultivation.

Queen.—A large Flower, a very free bloomer, and of good habits. Colour, a delicate light Pink, and a beautiful Rosy Vermillion Corolla.

Prince of Wales.—A very large bold Flower, and good substance. Colour, a bright Crimson, with an extraordinary large Violet Corolla. Magnet is also a large long Flower, good substance, habit, and a free bloomer.

To prevent disappointment, which is too often the case with new Flowers, the public are requested to come and see them before purchasing. Early orders are solicited, as the stock is limited, having broke very sparingly. A specimen of each will be open to any three Seedlings of 1843, grown from young plants, for the sum of 5*l.* To be exhibited at the West Kent Exhibition, held at Blackheath, in June next. N.B.—If accepted, notice to be given this month.—Bromley, March 12, 1844.

FUCHSIA.—MARNOCK'S Princess Sophia.—This beautiful FUCHSIA, which was raised by an Amateur, and purchased by Messrs. Marnock and Manley, is a dazzling vermillion; thick, glossy, substance; large tube, and, excessively brilliant; corolla, dark purplish rose, well expanding and forming a beautiful contrast from the sepals. Plants in April, 10*s.* 6*d.* each; an allowance to the trade if three or more plants are taken at a time. Their Catalogue of Fuchsias, Verbenas, Cinerarias, &c., containing every variety worthy of cultivation, with many new varieties of Cinerarias, &c., not yet let out, is in the Press, and will be ready in a few days, and may be had on application at their Nursery, Hackney, near London.

N.B.—Every description of choice Flower-seeds, at advertised prices.—March 13, 1844.

NEW DAHLIAS.—SPARY'S "LADY ANTROBUS" and "AURANTIA."

E. SPARY begs respectfully to call the attention of Florists and Amateurs to the above new and distinct Seedlings, which have received prizes at the following first-rate Exhibitions, viz.:—Salthill (1st), Portsea, Salisbury Plain, Chippenham, London Floricultural Society, Stockwell, Surrey, &c. For description, notices of the Press, &c., vide *Gardeners' Gazette*, 4th Nov., *Gardeners' Chronicle*, 11th Nov., also the November Number of the "Gardener and Practical Florist," for Mr. Glenny's opinion. As the number of dry roots would not allow all orders to be executed, strong healthy plants will be sent out by the first week in May. Lady Antrobus, 10*s.* 6*d.*, Aurantia, 7*s.* 6*d.*, with the usual discount per dozen. Also the select new and old varieties, at Catalogue prices.—Hungerford, March 12.

FUCHSIA AND DAHLIAS.

J. JONES, Florist, Ackworth, near Wakefield.—Fuchsia Bellissima is a delicate and pretty variety, of moderate size, Tube light-pink, Sepals tipped with green, and expanding freely, showing a well-formed Corolla, of a deep rose colour, which forms a good contrast to the other parts of the Flower; it appears to be of good habit, blooming freely.—See Dr. Lindley's opinion, Nov. 25, 1843.

DAHLIAS.—Delectus (Jones's), good form, dark purple, height, 4ft., 7*s.* 6*d.*

Imperator (Jonks's), fine crimson, scarlet, well up in the eye, fine form, 4ft., Plants, 5*s.*

Zechin (Jonks's), dark velvetty-maroon, good form, rather coarse in the petals, 5ft., Plants, 5*s.*

Dyson's Vanquisher—fine rose, good size and form; has taken several first Prizes, height, 5ft., Plants, 7*s.* 6*d.*

J. J.'s list of Dahlias, Geraniums, Fuchsias, &c., containing a full description of the above, may be had on application.

CHARLES DALY & SON, Nursery & Seedsmen, Coleraine, beg to inform the Trade that they have a quantity of One year Seedling Thorns, at 1*s.* 6*d.* per 1000. Also upright Irish Yews, 1 to 1½ ft., at 4*d.* each. Bays, 3 years in pots, 25*s.* per 100. Portugal Laurels, good Plants, at 6*s.* per 100. Laurels, 1½ to 2ft., 20*s.* per 1000. Some Hollyberries, at 5*s.* 6*d.* per bushel. Also a quantity of fine Pine apple Plants, fruiting and successive, warranted clean, from 1*s.* to 3*s.* each, delivered free in Glasgow, Fleetwood, and Liverpool.

TRUE HIGHLAND PINE.

JAMES GRIGOR begs to announce to the Land Proprietors of England, that he has received a supply of the true HIGHLAND PINE PLANTS, raised from Seeds collected on the Mountains of Strathspey, in the North of Scotland, where the tree is indigenous. These plants are of the variety so highly prized for producing hard and durable timber, known as the *Red Deal*, and formed part of the stock for which Mr. John Grigor was awarded the Premiums of the Highland and Agricultural Society of Scotland. It has been also strongly recommended by Sir Walter Scott, Mr. Don, of Forfar, and others, as far preferable to the common Scotch Pine, both as to the quality of its timber, and as a picturesque object. It will grow on almost all soils—clay, peat, sand, gravel, and even chalk—so that it is peculiarly fitted for all waste lands. It is worthy of a place, too, as an ornamental tree, for in old age it assumes much of the bold and contorted figure of the Oak. To the Landscape Gardener, who has to clothe the bold declivities of distant scenes, it is invaluable; and, indeed, whether viewed as an ornament, or simply as a forest tree to be cut down for railway sleepers, or blocks for wood pavement, or with regard to civil architecture generally, it is without a rival among the trees of Britain. Two-year-old picked plants, carefully packed, at 2*s.* 6*d.* per hundred. If taken in thousands, a considerable abatement will be made in price.

Old Lakenham, Norwich, March 15, 1844.

NEW HARDY ANNUAL.

VISCARIA OCULATA—DARK-EYED VISCARIA.

T. AND J. BACKHOUSE, Nursery and Seedsmen, York, have the pleasure of offering to the Public the above new and beautiful Annual, which is figured at page 59, (No. 10), of the "Botanical Register" for 1843. The blossoms are of a bright rose-colour, with a deep crimson eye, and changing to a pale purple. It flowers very abundantly through the greater part of the summer and autumn. It is a native of Algiers, and may be sown either in the open ground in spring, or raised on pots and planted out.

Packets, 2*s.* 6*d.* each, will be sent, on the receipt of a Post-office order, postage free, to any part of the Kingdom.

SLOUGH NURSERY, NEAR WINDSOR.
CHOICE SELECTION OF NEW DAHLIAS, 1844.

THOMAS BROWN directs attention to his beautiful DAHLIAS, particularly that unrivalled light flower, "LADY ST. MAUR," the superiority of which over every other of its class is too well known to need further comment. Strong and healthy plants will be ready for delivery early in May.

AURANTIA (Spary's)—Orange buff; fine form and petal. A very desirable show flower; obtained numerous prizes; 3 ft. 10s 6d

ALEXANDER (Brown's)—Maroon and crimson mottled; full and constant, centre well up, and a very useful show flower; 3 ft. 7 6

DELIGHT (Brown's)—Cream, veined and tipped with purple; petal of fine substance and high centre; very distinct to any in cultivation; 4 ft. 7 6

DESIRABLE (Brown's)—Shaded buff, quite new in colour; a good show flower; 3 ft. 7 6

LADY ST. MAUR (Brown's)—White, delicately tipped with violet purple; very deep and full, high centre, forming a beautiful outline; the petals are round, and smooth at the edge; habit of Perpetual Grand: it is decidedly the finest light flower ever offered. It attracted great admiration at Windsor, and was universally acknowledged to be the finest flower in the Exhibition; 4 to 5 ft. 10 6

NUBYTA (Brown's)—Bright crimson; a fine open-cupped petal, and a good show flower; 4 ft. 7 6

RAPHAEL (Brown's)—Dark maroon, beautifully shaded with light crimson; superior petal, of excellent form: a very novel and striking variety, and will be an acquisition to any stand; 4 ft. 10 6

REMBRANDT (Brown's)—Dark purple, very round and double, rising well in the centre, and a constant show flower. It was very successfully exhibited; 3 to 4 ft. . 10 6

EMMA NOKE (Dowding's)—Blush white, good general form and centre: a good useful show flower; 4 ft. . 10 6

ESSEX BRIDE (Turville's)—Delicate peach lilac, of excellent petal and form; 3 ft. . . . . (no discount) 10 6

LADY ANTRODUS (Spary's)—White and lilac, mottled; good form, constant, and very useful show flower; 3 ft. 10 6

NONPAREIL (Proctor's)—Ruby scarlet, of first-rate properties; extra show flower; 4 ft. . (no discount) 10 6

STANDARD OF PERFECTION (Keynes')—Crimson; of very superior form; 4 ft. . . . . (no discount) 10 6

MRS J. STEWART RICHARDSON (Union)—Brown ruby, great depth, and excellent show flower; 4 ft. (no discount) 10 6

T. B. has also Selections of fine Carnations, Picotees, and all other Florists' Flowers; Plants, Fruit trees, Shrubs, and general Nursery Stock.

A general Catalogue of Dahlias, with a List of Superb New Pansies, to be had on application.

NEWEST, CHEAPEST, AND VERY BEST FUCHSIAS AND VERBENAS.

FUCHSIAS.—12 fine choice distinct sorts, for . 7s. 6d.
12 extra very superior, selected from all new kinds sent out last season for the first time, for . 15 0

Such as Exoniensis, Enchantress, Balloonflora, Toddiana, Spyall, Cormackii, Deaniana, Prince Albert, Lancii, Frostii, Grenvillii, Fairy Queen (Bell's), Ivery ana, Gem (Ivery's), Nobilissima (Smith's), Majestica (Smith's), Defiance (Smith's), Robusta (Smith's), Stanwelliana, Transparens (Youell's), Deansii (Dean's,) Recurva (Dean's), Alice Maude Mary (Bell's), Princess Royal (Bell's), Brockmanii, Prince of Wales (Bell's), Lowryii, &c.

VERBENAS.—12 fine distinct varieties, for . . 3s. 6d.
" 12 extra and very superior, for . . 6 0

Such as Duke of Cornwall (Knight's), Speciosa (Kyle's), Princess Royal (Youell's), Howardiana (Low's), Prince of Wales (Wood's), Cærulea (Harrison's), Boule-de-Feu (Girling's), Tweediana picta, Minstrel Boy (Girling's), Rosy Queen (Halley's), &c. &c. &c.

Purchasers are requested to send the names of those kinds they already possess; and Mr. MILLER pledges to send them entirely different, and sorts such as will add beauty as well as novelty to their collections. Mr. M. is enabled to do this satisfactorily, having bloomed every new kind sent out last season. —See extensive list in this Paper of Feb. 17, 1844.

100 fine Hybridised Fuchsia Seeds, 7s. 6d; fifty, 4s.; Geranium Firefall, 5s.; Black Nemophylla discoidalis (plants) 1s. each.

The above will be sent post free, packed in stout tin cases, so as to warrant their arrival to any part in safety; or may be had in pots, carriage paid to London, and no charge for packing or hamper.—W. MILLER, Providence Nursery, Ramsgate, Mar. 15.

SPLENDID SEEDLING FUCHSIAS, PANSY, and AQUILEGIA.

W. ROGERS AND SON, SEEDSMEN and FLORISTS, beg to offer the *following*, which they can with the greatest confidence recommend.

SEEDLING FUCHSIAS.

No. 1, ROGERS'S UTTOXETER BEAUTY.—"*W. R. & Son.*—Your seedling is a flower of good substance, tube and sepals of a bright rosy red, corolla purple veination, petal very long and erect; *a very large and showy variety.*"—*Gardeners' Chronicle*, August 5, 1843. Plants 10s. 6d. each.

No. 2, ROGERS'S UTTOXETER RIVAL.—"*W. R. & Son.*—In the seedling now sent the tube is stout, with sepals of a rosy carmine, broad and tipped with green: they expand freely, showing the corolla, which is of a rosy purple. *This is a very large and bold flower.*"—*Gardeners' Chronicle*, August 19, 1843. Plants 10s. 6d. each.

No. 3, ROGERS'S PENDULA ELEGANS.—"Stout tube and sepals, which are broad and slightly tipped with green, which expand freely; corolla shaded purple."—*Hare's on's Floricultural Cabinet*, August 1843. A very good one Plants, 5s each.

In addition to the above opinions, W. R. & Son beg to state No. 1 is a variety of immense size and substance; the colour has a very rich glossy appearance, while the extraordinary length of the plaill forms one of the most distinct and splendid kinds ever offered. A fine plant was exhibited at the Uttoxeter Royal Horticultural Society, with branches extending from the main stem 12 to 18 inches, in full bloom, which shows it to be a free bloomer, and not merely blooming at the ends of the branches. It gained the first prize, and was much admired. The same remarks are applicable to No. 2, except that this gained the first prize for the best seedling, and allowed by the judges to be a superior variety. No. 3 is a fine variety, and very free bloomer; gained the first prize at the Lichfield Horticultural Society.

FUCHSIA ROGERSIANA, 2s. 6d. each.

The usual discount to the Trade on the above, when not less than six plants are ordered at one time, and on the following when not less than three are ordered.

PANSY—ROGERS'S LORD VERNON.—Upper petals crimson purple, lower petals laced with same, centre pale yellow, with an extremely large eye; this is of immense size and good form; a very distinct and fine sort. Plants 5s. each.

AQUILEGIA GRANDIFLORA.—This is a beautiful plant (a hybrid), flowers the colour of A. glandulosa, but twice the size. It has been several times exhibited at the Uttoxeter Royal Horticultural Society, and invariably won the first prize for Herbaceous plants, and particularly admired by all who saw it. Plants 5s. each.

Strong plants of the above will be ready to send out by post or otherwise the first week in April. A reference or remittance requested from unknown correspondents.

W. R. & Son's Catalogue of Dahlias, Pansies, Phloxes, Pelargoniums, Cinerarias, Verbenas, &c. &c., including many new varieties, may be had prepaid, on a prepaid application.

Agents for the above, Messrs. HURST and MCMULLEN, Seedsmen, 6, Leadenhall-st., London.—Uttoxeter, Staffordshire, Mar. 11.

GENUINE BEECHWOOD MELON SEED.

R. GLENDINNING respectfully begs to inform the Cultivators of the MELON that he has had presented to him by Sir JOHN E. SWINBURNE, Bart., Heads of the fruit variety of his delicious MELON; for besides being one of the very best sorts known, it is of easy cultivation and a good bearer. This opportunity will enable gentlemen to procure it *quite genuine*, which is rarely the case, as the following note will testify:—

"Beechwood, Feb. 5, 1844.

"*Sir*,—I send you a small parcel of the Beechwood Melon Seed. None that I have seen exhibited under that name, nor any that I have seen grown from Seed that has been bought, are of the true sort, but have obviously been intermixed with other varieties. I have grown no other for many years.

"Your obedient servant,

"To Mr. Glendinning. J. S. SWAINEY."

R. G. has also a few Seeds of the true SION FREE-BEARING CUCUMBER, a splendid variety which has been nearly lost.

Packets of the above sent by post free.

Beechwood Melon per packet . . . 5s.
Sion Free-bearing Cucumber per packet . 5s.

R. G.'s Kitchen garden and Flower-seeds have been selected with great care, and embrace all the new and good kinds.

Chiswick Nursery, near London, Feb. 16, 1844.

CHOICE PANSIES.

J. HENCHMAN begs to inform cultivators of the PANSY that he is now sending out healthy plants of six good seedling varieties, for 21s. the set. Also a few choice kinds at 15s. and 18s. per dozen.—Edmonton, March 1844.

NEW CAMELLIAS, FUCHSIAS, and CINERARIA.

J. HALLY, NURSERYMAN and FLORIST, Blackheath, begs to offer for sale the following SEEDLING CAMELLIAS, which have been highly approved of by all who have seen them:

PULCHELLA ROSEA.—Figured and described in the "Florist's Journal" for July last; a finely formed delicate rose-coloured Flower, perfect in shape, rising well up in the centre. Good Plants, each, 5*l.* 5*s.*

ALBA MULTIFLORA.—Colour very pure white, with sometimes a delicate pink stripe; petals thick, cupped, and round. The chief novelty and merit of this variety consists in the abundance with which it blossoms, the flowers appearing at every joint throughout the young wood, so as when in bloom to give the plant the appearance of bearing racemes of flowers. Strong plants, 1*l.* 11*s.* 6*d.*

J. HALLY can confidently recommend the following 6 SEEDLING FUCHSIAS, which he intends sending out early in April; they are all very distinct and beautiful varieties.

1. SANGUINIVEA.—Tube and sepals clear delicate white, with crimson corolla; of excellent close habit. This very distinct variety gained the seedling prize at the West Kent Floricultural Exhibition, Sept. 6, 1843. For its character see *Gardeners' Gazette*, Sept. 9th, in the account of the said exhibition, described as shown by Mr Branscombe. Price 7*s.* 6*d.*

2. FAIR HELEN.—Tube and sepals white, corolla scarlet; a very neat Flower, of good habit, exhibited at the Surrey Zoological Gardens, at the September show, and universally admired. 5*s*

3. BOYDII.—Fine thick scarlet tube and sepals, corolla large and bright crimson; of bold habit. 5*s.*

4. WAT TYLER.—Tube and sepals very large, light rose; corolla large and scarlet. A large flower, and most abundant bloomer. 5*s.*

5. KING JOHN.—Habit of plant and colour of flower like Chandlerii, but twice the strength and size. A noble variety. 5*s.*

6. MARGINATA.—Very large flower; tube and sepals scarlet, corolla (large and expanding well) crimson, having a scarlet margin round each petal. Plant of particular fine habit. 5*s.*

The above collection of Fuchsias may be had, by taking the whole, for 30*s.* The usual allowance to the trade on the above.

Also will be ready for delivery at the same time with the Fuchsias, PIPER'S "PRINCESS ROYAL" CINERARIA (not yet sent out). This beautiful variety obtained the seedling Certificate at Chiswick, and first prize at the Regent's Park last season. Price 7*s.* 6*d.* each, with the usual allowance to the trade, when four plants or more are taken

A general Collection of Camellias, Fuchsias, Azaleas, Ericas, Cinerarias, &c. Veronica speciosa, 21*s.* each; Rosa Devoniensis, from 18*s.* per dozen.

WM. JOHN CORMACK, AGRICULTURAL SEEDSMAN by Appointment to His Royal Highness PRINCE ALBERT, New Cross, Surrey, and Bedford Conservatory, Covent Garden, beg to call the attention of the Nobility, Gentry, and Agriculturists in general to his combinations of GRASS SEEDS for Permanent Pasture, the Alternate Husbandry, Parks, Lawns, &c. (as recommended and practised by his partner, the late Mr. GEORGE SINCLAIR, Author of the "Hortus Gramineus Woburnensis.") Upwards of 2500 acres have been converted to permanent pasture by this establishment with the greatest success. Parties requiring Seeds are respectfully requested to state the nature of the soils. Mangold Wurtzel, Carrot, and Turnip-seed of excellent sorts, saved from transplanted bulbs. Garden and Agricultural Seeds of the best quality and most approved kinds.

N.B.—Cormack's British Queen and Prince Albert Peas, at 3*s.* 6*d* per quart.

AGRICULTURAL SEEDS.

WHITE BELGIUM GREEN-TOP CARROT, 1*s.* per lb.; Altringham Carrot, 1*s.* per lb.; Large Green-top Orange Carrot, very thick shouldered, and well adapted for shallow soils, 1*s.* 6*d.* per lb.; Long Red Mangel Wurtzel, grows well out of the ground, 1*s.* per lb.; Fine long Yellow Mangel, produces roots as large as the red, 1*s.* 6*d.* per lb.; Yellow Globe Mangel, 1*s.* per lb., Lucerne, 1*s.* per lb.; Italian Rye Grass, 8*s.* per bushel; Pasture Grasses of all kinds, fine mixed Grasses for Lawns; Skirving's improved Swede Turnip, 1*s.* per lb.; Laing's do. 1*s.* per lb.—W. J. SAUNDERS, Seedsman, 48, Cheapside, London.

Garden and Flower Seeds of every kind, as advertised by other houses.

GREEN GLOBE TURNIP SEED.—A Grower of Turnip Seed has 150 bushels of fine Green Globe Turnip Seed. Samples and price sent to order by applying to W. STENT, Nurseryman, Stockwith, near Gainsborough.

SEEDS.—Belgium Large White Carrot, 1*s.* per lb.; Mangold Wurtzel, Long Red, Orange Globe, and Red Globe, 1*s.* per lb. each; Le Couteur's Belle Vue Talavera Wheat, 11*s.* per bushel; Kinbury Skinless Barley, 8*s.* 6*d.* per bushel; Meadow and Pasture Grass Seeds in Mixtures, suited to soils, &c., at 32*s.* per acre: Mixed Sorts for improving old Grass Land, 1*s.* 3*d.* per lb.; Lime Sorts for forming Lawns, &c., 1*s.* 6*d.* per lb. Price Catalogues of Turnips and other Seeds are ready. Kitchen Garden and Flower Seeds.—GEORGE GIBBS AND CO., Seed-smen, &c. 615 the Agri. Soc., 26, Down-street, Piccadilly.

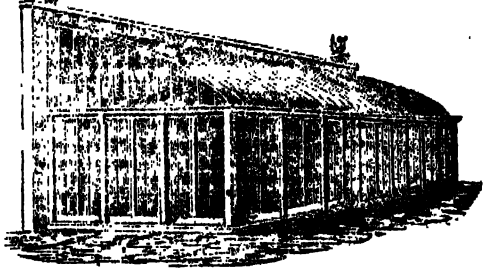
TO GENTLEMEN, FLORISTS, AND OTHERS.

TO BE SOLD BY AUCTION.—By Mr. IZOD, at the Auction Mart, Bartholomew-lane, on Tuesday, March 19, at 12 for 1. A Choice Stock, the entire property of Mr. W. Alexander, of Lamb Farm, Kingsland, comprising a FINE COLLECTION of CARNATION PICOTEES, ROSE TREES, GERANIUMS, and other choice plants. The Carnations comprise Twitchet's Don John; Martin's Splendid; Puxley's Prince Albert; Hepworth's Brilliant True Briton; Lowe's Grand Sultan, Marchioness of Westminster, Lord Palmerston; Maudsley's Beauty of Woodhouse, Romny Bess, &c. Picotees—Nelli Secundus, Williams' Mrs. Hamilton; Robinson's Nottingham Hero; Ely's North Midland; with a choice stock of Geraniums, comprising the leading varieties, 200 Dwarf Roses, and other miscellaneous plants. May be viewed on the morning of sale, and catalogues had at the Mart, and of Mr. IZOD, at his offices, 2, Warnford-court, Throgmorton-street, City.

TO GENTLEMEN, FLORISTS, and OTHERS.

MESSRS. PROTHEROE AND MORRIS will submit to public competition, at the Auction Mart, Bartholomew-lane, on THURSDAY, MARCH 21st, 1844, FRIDAY 22nd, and TUESDAY, 26th, at 12 o'clock, about 2000 Standard and Dwarf ROSES, consisting of Bourbons, Perpetuals, Hybrids, Chinas, &c. CAMELLIAS, well set with bloom, DAHLIAS in dry roots, &c.—May be viewed the morning of sale; Catalogues may be had at the Mart, and of the Auctioneers, American Nursery, Leytonstone.

TO BE SOLD, a Quantity of VINE PLANTS—all PRUNED SORTS: One-year old Cuttings now ready for Planting, raised under the directions of Mr. Stafford, late of Willersley Gardens.—Direct to Mr. JAMES RAWLINSON, Belle Vue, Matlock Bath, Derbyshire.



TO BE SOLD, about 1000 clean, robust, well-grown Succession QUEEN PINE PLANTS, from 2*s.* 6*d.*, 3*s.* 6*d.*, to 5*s.* per plant; those at 5*s.* will fruit this autumn, delivered free in London. Gentlemen in want of such will find this an advantageous opportunity of supplying themselves. Application to be sent to Mr. KERNAN, Seedsman, 4, Great Russell-street, Covent-garden, or to Mr. TRUDGEN, the Grower, Forest-hill, London.

For Particulars and to treat for Lease apply to Messrs. H. and R. B. SEWELL, Newport, Isle of Wight.—Mar. 15, 1844.

COTTAM AND HALLEN, ENGINEERS, IRON FOUNDERS, &c. &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL-ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices, in consequence of the present depressed state of the Iron Trade.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public, or Private Buildings, &c., with COTTAM'S PATENT, or ROGERS' BOILERS. After 15 years' experience, and having fixed upwards of 1500 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale. For the convenience of those who wish to fix their own Apparatus, they have affixed the following low prices:—

Cottam's Patent Boiler, 18 Inch . . . £2 15*s.* 0*d.*
Rogers' Boiler, small size 1 17 0
Larger in proportion.

Hot-water Pipe, at 2, 3, and 4 inches, at reduced prices.

The TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

GARDEN ROLLERS 18 inches long, 34*s.*; 20, 44*s.*; 22, 50*s.*; 24 inches, 60*s.*; 26, 75*s.*; 28, 84*s.*; 30, 105*s.* each.

CAST-IRON RICKSTANDS, 2 feet six inches high, 5*s.* 9*d.* each. Garden Engines, Mowing Machines, Garden Chairs, Superior Garden Tools of all kinds, Garden Vases and Pedestals in great variety, and every description of Horticultural Articles, Agricultural Implements, and Furnishing Ironmongery; Dr. Arnott's Stoves, Anglo-Belgian Cooking Stoves; Broiling Stoves. The above low prices being on account of the depression in the Iron Trade, are subject to future alterations.

STRONG IRON HURDLES, 2 ft. high out of the ground, 6 ft. long, with five horizontal bars, weighing about 36 lbs., 3*s.* 6*d.* each. Light Cattle Hurdles, 3 ft. 6 in. high, weighing 42 lbs., 4 0 ,,
Strong do. do. do. 45 lbs., 4 4 ,,
Ox Hurdles, 4 feet high, do. do. 60 lbs., 5 5 ,,

BEST WIRE, for STRAINED WIRE FENCING, at 9*s.* 6*d.* per bundle of 150 yards each. Uprights for ditto, 7*d.* each. The Improved continued, and every kind of Fencing, Fancy Wirework.

HAND-GLASS FRAMES for Cucumbers, &c., 18 inches square, 3*s.* 6*d.*; 20 inches, 4*s.* 6*d.*; 22 inches, 5*s.* 6*d.* each.

CAST-IRON FLOWER-STAKES, 4 ft. long out of the ground, 7*s.*; 4 ft. 6, 8*s.*; 5 ft., 11*s.*; 6 ft., 15*s.*; 7 ft., 20*s.* per dozen.

SHOW-ROOMS at the Manufactory, No. 2, WINSLEY-STREET, where every information may be obtained.

RENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance, can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of Iron will be found cheaper than of any other material. MR. RENDLE, of Plymouth, has kindly undertaken to receive Orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

MELON SEEDS.—A very liberal Remuneration will be given for some PERFECTLY PURE AND GENUINE SEEDS of the under-named Melons; or Seeds procured the last year direct from China, Cabul, and Candahar, will be given in exchange:—Striped Hoosainee, Daree, Geree, Garmek, Melon of Gerger, Nukshevan, Sweet Melon of Ispahan, and Italian Green Seed.

Application to Mr. G. MILLS, Gardener, Gunnersbury Park, Acton, Middlesex.

The Gardeners' Chronicle.

SATURDAY, MARCH 16, 1844.

MEETINGS FOR THE FOLLOWING WEEK.

TUESDAY, March 19	Horticultural	3 P.M.
	Linnean	8 P.M.
WEDNESDAY, March 20	Meteorological	8 P.M.
	Society of Arts	8 P.M.

A WORK has lately been published by Dr. Von Martius, on the EPIDEMIC DISEASES OF POTATOES, and to this work we shall again have occasion to refer. He enumerates all the diseases that have been observed from time to time in Potatoes, and describes more particularly two forms which did extensive damage to the Potato-crops of Germany in 1841. These he calls, in German, Stock-fäule, and Räude—in literal English, Stem-rot, and Scab. It is to the first of these diseases, stem-rot, that we wish to draw attention as resembling, in many of its symptoms, the *moist gangrene* we spoke of in our last article. There is, however, this difference between that disease and the one we are about to mention, that the former attacked only leaves and fruits, and was accompanied by the presence of a large quantity of moisture, whilst this attacks the tuber, an underground stem, and is characterised by a diminution of water in the tissues of the plant. It is, in fact, a form of *dry gangrene*; and Martius calls it, Gangræna tuberum Solani.

When Potatoes are attacked with this disease, the first thing that is observed is a drying-up or shriveling of the tuber. The skin loses its ordinary lustre, becomes wrinkled, and shows at last little irregular spots, of a dark-brown colour, which, as the disease progresses, run together into larger spots. In these places the skin seems thicker, and has the appearance of having been rubbed against something. Subsequently the tissue of which the skin is composed becomes loosened and torn; and by the breaking-up of its continuity it assumes the appearance of the bark of an old tree. Sometimes the skin is split up into distinct patches, like scales. At the commencement of the disease, the interior of the tuber does not suffer; but, at last, a change of colour takes place in the tissue under the spots on the skin. Patches of a yellow or brown colour are observed, which are at first isolated, but at last run one into the other. These patches are drier than the surrounding tissue; but up to this period in the appearances of the disease, no changes have taken place that render the tuber unfit to eat.

As the disease advances, little warts or excrescences form on the skin, which are of a dark colour inside; they are at first small, but keep on extending, and at last run one into the other. From the surface of these warts a fungus, belonging to the mould tribe, is observed to project. The Potato now begins to emit a disagreeable odour, and its physical character is generally changed. Its specific gravity, which in a state of health is 1.163, becomes successively reduced as the disease proceeds, and at last is about 0.9. When in this state, it is frequently attacked by a species of Acarus, the A. farinæ, which feeds upon the grains of starch. If the Potatoes are planted with this disease, in no case do they put forth healthy shoots. In the commencing stages, the eyes put forth shoots which rise above the ground, but soon perish. In the latter stages, the whole tissue of the Potato is involved in the disease, and on cutting into it, it presents a dark-coloured disorganised mass, very dry, and not unlike the appearance of a truffle. The attempt at putting forth shoots now results in the formation of little knobs, varying in size from a quarter of an inch to an inch in circumference, and having a red or rose colour on the outside.

On examining the tissues under a microscope, it will be found that the cellular tissue of the skin has lost its transparency and become of a brown colour, and that of the interior has lost its brightness, as well as its moisture and whiteness. The starch grains gradually disappear, and cells filled with air and a yellow fluid occupy their place. Many of the cells are torn, and the intercellular passages are filled with a brown fluid.

Scattered between the cells in all directions will be seen dark-coloured, opaque grains, of varying form and size. These grains do not develop any further, but at last burst, and in their appearance and history resemble the Protomyces, or primitive Fungus germs of Unger. On cutting into the little knobs, masses of the fibres of a Fungus are observed, which at last make their way to the surface, and there either fructify or become shrivelled into a whitish layer. Sometimes the fibres of this Fungus, which are very delicate and transparent, are found throughout the whole mass of the diseased tuber. On examining these fibres, they present two distinct forms, the one being probably a variety of the other. Martius has named it *Fusisporium solani*.

Potatoes thus diseased have been chemically examined by Dr. Buchner. The starch of the Potato does not appear to undergo much change as long as the tubers are kept from the influence of moisture, or that the dry form of the gangrene does not give way to a moist one, which is sometimes the case. The albumen of the Potato entirely disappears. The greatest alteration is in the water, which is reduced to half the quantity that exists in healthy Potatoes.

In healthy Potatoes, the water is	.	73 parts.
In diseased ,, ,,	.	35 ,,
In healthy Potatoes, the dry matter is		26 ,,
In diseased ,, ,,	.	64 ,,

The lignin becomes of a brown colour, and is converted into humus. A more accurate analysis than the above has not at present been obtained. The following, however, is an analysis of healthy Potatoes by Pfaff:—

Water	76.6
Starch	11.2
Ligain	7.8
Mucus and Salts . .	3.7
Albumen	0.7

These figures are the mean of nineteen analyses:—

We are not aware that this form of disease has prevailed extensively in England; but we have lately received communications from correspondents complaining of their Potatoes, and in some instances we make little doubt that they are suffering from the disease we have just described. We wish our correspondents would be more particular in their descriptions of the diseases of plants, or, which is far better, send us up specimens for our own examination.

With regard to the causes of this disease, nothing certain is at present known. In Germany it has occurred in all soils and in all weathers. It has occurred to almost all sorts of Potatoes, and after all modes of planting and gathering, so that many have been inclined to attribute it to the influence of contagion; whilst those who are advocates of the doctrine that all diseases spring from the sporules of fungi, will at once conclude that the existence of the fungus in this disease is a proof of its having originated in their presence. We shall, however, consider the subject of contagion and infection in their relation to the propagation of disease amongst plants, in a future article.

For the present we can only say, that for the prevention of the dry gangrene in Potatoes every precaution should be taken in planting them, to secure their healthful growth. The conclusions of Von Martius are as follows:—The newer the variety is the better. The Potatoes intended for seed should be grown separate from the rest. The seed-Potatoes should not be kept heaped up in damp cellars, and allowed to shoot before they are planted, and they should never be cut for sowing till they are brought into the field.—*L. E.*

We are sure that all sensible gardeners who are striving after eminence in their art, will have read with interest the various papers by Mr. W. Wood, which have from time to time appeared in our columns. We would now invite their very particular attention to a communication, nominally on FUCHSIAS: but really on the whole *rationale* of potting plants, the commencement of which appears in our columns of to-day. They may not, perhaps, entirely agree in all the views of Mr. Wood, but they will find in the principles which he inculcates, much that they cannot reflect upon without advantage.

We are too well aware that many gardeners disregard first principles, and rely entirely upon what *they* call experience, but what *should* be named blind chance. It is not, however, the intelligent men among them who do this; and we trust that the day is near when no one will care to avow it. For however reluctant cultivators may be to apply the first principles of Horticulture to practice; whatever success may attend the attempts of the ignorant, jealous, or crafty, to throw obloquy upon the advocates of a rational system of gardening; and however difficult it may appear to apply theory to practice; we may rest assured that the day is near at hand when first principles, though last learned, will be universally recognised as the only guide to be safely followed.

Gardeners are, as a body, far better informed and more intelligent than any men in their own condition of life; and it is only necessary for them to turn their attention steadily to an examination of the causes that produce the results with which they are familiar, to win for themselves a really high station in the estimation of the world. It is an earnest striving after perfection that alone leads to distinction. For attempting to inculcate those truths, ourselves, Mr. Wood, and others, have been assailed in the most unworthy manner. The attacks made by a disreputable portion of the press upon the course we have seen fit to take on this subject have been unjust, false, virulent, and vulgar; discreditable to the taste and temper, and disgraceful to the character of their writers.

A popular authoress, when speaking of her hero, has happily observed that—"The more he learned to see, the more afraid of darkness he became. He was very much afraid of ghosts; yet the ghosts which he feared have been known among men from time immemorial. *Ignorance*, a wonderfully large lady, clothed in glittering white texture; *Selfconceit*, her long-necked child, who always treads in the footsteps of her dear mamma; and *Boasting*, which must be the ghost of an old French language-teacher, who in his lifetime had been connected with these ladies, and often been seen in their company." Let all Gardeners be as much afraid of ghosts as Cornet Charles, and, like him, take for their motto "FORWARD! MARCH!"

FUCHSIAS.

For easy culture, elegance, and long continuance of bloom, the Fuchsia is probably unequalled. Its fitness for growth in pots or open borders, for portable specimens, or for permanent effect, and, above all, its adaptation to almost every kind of soil (under proper treatment,) give it more than ordinary attraction. Though Nature has omitted to endue it with her most spiritual attribute of odour, she has so mantled it with the "perfection of beauty," that the most fastidious taste could not imagine a more graceful and brilliant form of vegetable structure. There is scarcely, however, another race so generally grown respecting whose cultivation such opposite opinions are entertained. Whilst one man recommends exclusively the annual growth from the root, directing each preceding season's shoots to be removed, a second as strenuously maintains the value of the previous year's growth, as the best means of ensuring prolific bloom from the exhausted, but partially renovated source of by-gone vigour.

As the permanent character of plants may, to a great extent, be determined by their capability of accumulating such an annual supply of sap as may be sufficient to maintain their fertility unimpaired in successive seasons, it may be confidently assumed that the constitutional vigour of all plants is impaired in proportion to their excessive fertility, which being the ultimate function of vegetable life, can only be continued by the reproduction of the organs (or buds) essential to the formation of bloom. The Fuchsia is one of the most striking instances of fertility in plants; and, apart from other objections to the modes of cultivation just mentioned, which however will be productive of favourable results by good management, it may be stated as certain, that a better method is to be expected for managing all plants whose tendency to bloom is strictly commensurate with their annual amount of growth; a habit which is strongly characteristic of the present genus. The management of Fuchsias, to which the present remarks are introductory, commenced from their first stage of growth in the 2d and 3d weeks in March 1843.

To successful cultivation the following qualifications appear requisite:—A knowledge, 1st, of the constitutional habits of the plants to be grown; 2d, of the nature of the materials (soils, &c.), best adapted for their growth; 3d, of the extent to which such soils, &c., can be applied; 4th, skill to maintain the means essential for growth by a due regulation of light, air, heat, and moisture.

Before proceeding to practical remarks, it will be as well to refer the reader to opinions given in a previous Paper, viz., that 1st,—"It is the elementary condition of an organised being, which favours the ultimate development of its parts. 2d, That a uniform circulation of the fluids necessary for the highest objects in Horticulture, is the result of adapting the arrangement, proportions, textures, and qualities, of the materials employed in cultivation, to the organic structure of plants, and to the external agencies which operate upon them throughout their entire growth."—(*Gardeners' Chronicle*, 1843, p. 820.)

Admitting the correctness of these conclusions, the following inference is clearly to be drawn from them, namely: that there is no arrangement of soil essential to the perfect condition of a plant, which is not proportionately essential throughout its whole period of growth. That the fertility of plants is regulated by the modified action of atmospheric and solar agencies upon other elements in Nature, is too well known to require proof; but it is equally certain that the most fit medium by which such agencies can be applied is not equally well understood; or why is it that opinions are still given, that the condition of certain plants has been caused by the presence or absence of some single substance? Why is it that we hear of such various combinations of matter for the conveyance or suspension of the elements of food for plants? Why is it that so many ingenious external contrivances are sought out and applied as attracting influences and channels to convey the vital elements of Nature to every organised being, however diversified its structure?—as though a perfect system of cultivation would be found in connexion with the greatest extent and influence of atmospheric agency. The next generation will smile at the fact that their predecessors, with all their skill, were advocates of such internal materials for the growth of plants as would most readily imbibe the vivifying influence of atmospheric and solar agency, in connexion with external structures which would be the least pervious to them.

The first general truth in the department of Horticulture, to which the present subject refers, is, that every operation of art implies a limitation of the agencies of Nature; the successful application of the former being exactly in proportion to the correct recognition of the laws of the latter.

In illustrating these remarks I must once more advert to the primary truths upon which a correct arrangement of soils depends in artificial cultivation; and the reader is particularly requested to compare the principles stated at p. 848, (1843), with the following:—

§ 1. The particles of which all matter consists being subject, by the law of attraction, to form solid bodies, are, in the absence of a modifying agent, unfavourable to that condition which admits the action of other essential agencies to growth. The soils employed for plants in pots being circumscribed, are subject to the force of attraction, by the increased pressure of their parts towards and upon each other.

§ 2. As the force of attraction in matter, implies a division of its parts to be attracted (*or vice versa*), it also implies an agent capable of acting singly upon its parts.

§ 3. The force of attraction, by the pressure or cohesion of matter, being in proportion to the number and closeness of its parts in any given body, it follows that any arrangement by which such parts are diminished or increased, must necessarily be a modifying power, or agent, whereby the force of attraction is governed.

§ 4. The primary agent in Nature, which operates upon the form or arrangement of matter, previous to its decomposition, or affinity, is mechanical *force*.—(Herschel).

§ 5. If the attraction or cohesion of matter may be modified (§§ 3 and 4) by *mechanical* agency, it may be inferred that such a modifying *power* or agent is essential to the condition of other agencies acting upon matter. The proportions of soils in pots being subject to attraction by pressure, increase the force of attraction by lessening the distances of the individual parts, and diminish the force of attraction by increasing the distances of such parts (§ 3.)

§ 6. As matter, when circumscribed, is subject to an undue attraction of its parts (§ 1), and as mechanical agency is a modifying cause of attraction (§§ 3 and 4), it may be assumed that a just mechanical arrangement is essential in all soils employed in growing plants.

§ 7. As the force of attraction is in proportion to the number of parts in any given body, (§ 3), and is inversely as the distances between such parts, it follows that mechanical agency should be strictly in proportion to the number of such parts.

§ 8. All elementary substances are capable of entering into combination with each other only in fixed or definite proportions, and not arbitrarily. (Herschel.)

§ 9. What is thus true of combinations may be assumed to be true of mixtures; and therefore the proportions of soil in which plants are potted should also bear a strict relation to each other.

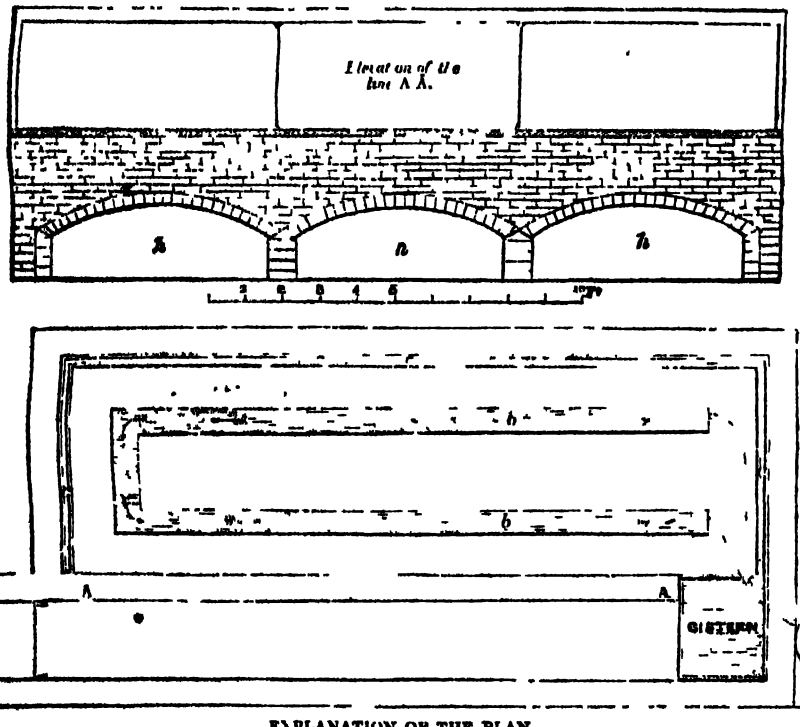
§ 10. As the soils in which plants are potted may be acted upon by other agencies, only according to their uniform condition,—1st, mechanically (§ 7); and 2d, chemically (§ 8); it may be assumed that a law of mutual relation is the only true basis of a perfect arrangement of soils for the growth of plants.

§ 11. The fitness of pots for a perfect arrangement of soil, will be in proportion to their uniform admission (externally and internally) of the mechanical, chemical, atmospherical, and solar agencies, essential to the support of plants (§ 9).

§ 12. As the mechanical and chemical properties of soils are modified by atmospheric and solar action, the latter exerting an opposing tendency upon the former, it may be assumed that the mutual relation or counterbalance of these opposing agencies to the growth of plants constitutes the law of equilibrium, by which the vital elements of support to plants are held in solution for such period as their organic structure, or assimilative power demands.

§ 13. As all plants are sustained by agencies peculiar to their organic structure, and possessing a mutual relation and dependency, it is shown by § 8, that the absence of one agent cannot be supplied by the excess or modification of another.—*William Wood, Pine-apple Place.*

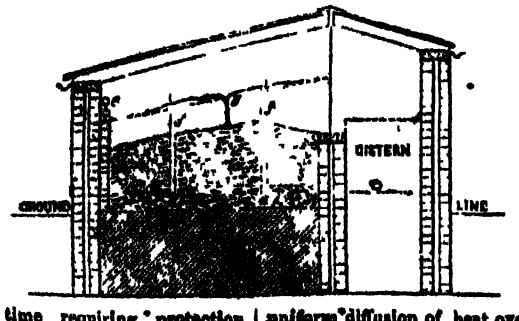
(To be continued.)



PLAN OF A MELON PIT.

By Mr. R. Glendenning, Nurseries, Turnham green.

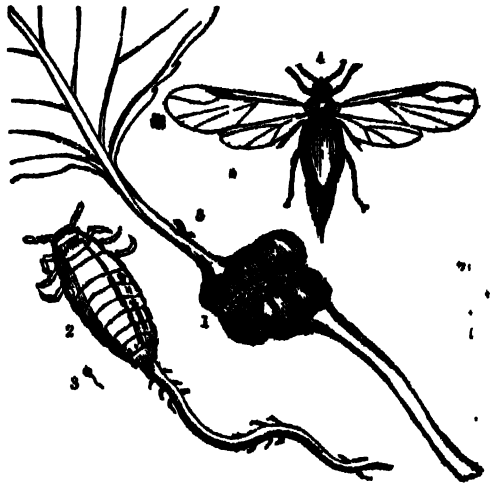
Mr. Knight has very justly remarked that "there is not any species of fruit at present cultivated in this country which so rarely acquires the greatest degree of perfection which it is capable of acquiring in our climate as the Melon." *



One of the great evils attending the common mode of producing the Melon in this country is the practice of raising them on dung-beds, where the roots are permitted to descend into the rank decomposing material under them; the plants, of course, grow very luxuriantly, in consequence of receiving an immense supply of impure and improper food, which is a fact well known by all practical gardeners. In order to obviate this evil, I have been employed by a scientific gentleman in this neighbourhood to design a pit for the culture of the Persian varieties of Melons; his object is to produce them in the highest possible perfection, which I am quite sure cannot be accomplished on a common hot-bed, for Persian Melons are much more difficult to manage than the kinds in general cultivation.

* Knight's Hort. Papers, p. 191.

EXPLANATION OF THE PLAN.



A, Burbidge and Healy's Boiler.
b b, Iron troughs *c c*, Pipes.
d d, Iron troughs as at *b b*, in Plan.
e e, Pipes as at *c c* in Plan.
f, f, Copper tubes fastened to the troughs to admit steam when required.
g, Wire-trellis on which to train the plants.
h, h, h, Convenient places for the growth of Seakale, Rhubarb, or Asparagus, or keeping tubers of any kind during winter.

This pit is intended for Melons in summer, and to preserve Pelargoniums, or other plants in winter. As the object in constructing it is more for the purpose of experiment than the permanent culture of Melons, I have designed it so that Vines may be substituted without any alteration whatever; indeed, any kind of plant, which such a structure is capable of resolving, and at the same time requiring protection and a warm temperature, may be very advantageously introduced, the hot-water apparatus being so contrived as to command both bottom and surface-heat, either separately or conjointly. For the purpose of supplying soft water for the plants, I have placed a slate cistern at one end of the pit, in order to collect the rain-water from the roof. The soil, if permitted to come in contact with the iron troughs, would, of necessity, become dried, and totally unfit for the roots of any plant. With a view to obviate this, I have placed rough flint, or other stones, over the bottom of the bed, and around the troughs, to prevent immediate contact, and at the same time, to admit of a more uniform diffusion of heat over the bottom of the pit, so that the soil which rests upon it may be more regularly heated. The other advantages and conveniences of this pit will be apparent from the above plan and section, without further remark.

ENTOMOLOGY.—No. LVI.

The Poplar-gall Aphis (*Eriosoma lanuginosa, Lindley*).—Having recently given the histories of the Elm-tree-gall Aphis and the American Blight, the economy of another species, which is a genuine Eriosoma, may not prove uninteresting, especially as it is the animal which led to the destruction of the Poplars at Bresham. In the early part of August and September, I have frequently observed excrescences upon the midrib and stalks of the Poplar leaves (fig. 1), which are invariably at the back; if the seeds of the foot-stalk be twisted in contrary directions, the suture in these galls will readily open, and the contents will be exposed to view. The galls are green with a rosy tint, more or less convex, with an irregular surface, and very thick comparatively; they generally contain a very considerable number of wingless individuals, varying in size; and I have seldom found more than four or five winged ones in them. The inner surface is covered with liquid globules, powdered over and resembling a vast number of eggs of all sizes, which soon dry up and disappear on being exposed to the air and light; the old exuviæ are also scattered about, and amongst them I detected some young Eriosomas with remarkably long tails (fig. 3), which were white, and appeared to be of a cottony substance; and it seemed as if the skins on moulting had been strung upon this appendage, for I have little doubt that the six minute claws visible at short distances are the skins from the six legs, in which case there is evidence of the specimen represented having moulted at least thrice (fig. 2). These little apterous Eriosomas were very pale-green, with black eyes and short 4-jointed horns. The winged specimens (fig. 5) were also very pale-green, the head and thorax dusky, the eyes black, the horns rather short and 6-jointed, with a seventh joint or minute tubercle at the inside of the apex; they were powdered over with pearly white, and the apex of the abdomen was woolly and destitute of tubes (fig. 4); the wings were colourless, with a large pale fuscous stigmatic spot, a large marginal cell, with three oblique nervures beyond, the first not forked at the apex (*), and the second and third uniting at the base; in the inferior wings the basal nervure forms a trident; the legs are short, especially the anterior, and slender, the feet are two-jointed, the basal joint minute, the other terminated by two claws.

The Poplar and Elm-tree galls are formed by a wingless female, which in the spring fixes upon a bud or stalk, and, piercing it, the extravasation of the sap causes the vegetable matter to assume an unnatural and distorted shape, and gradually expanding as the insect buries itself deeper in the tender tissue, it is at last completely enveloped. There she becomes the parent of a large family, sometimes producing eight daily; and by giving birth to young Eriosomas instead of laying eggs, the brood increases at a prodigious rate; for they grow rapidly, undergo their moultings at very short intervals, each one speedily becoming a mother in its turn; and at a later period of the year winged females appear: so that before the original founder of the colony dies she is surrounded by a numerous offspring, removed by many generations. Here, as, indeed, everywhere, we see the wisdom of the Creator in his works: the duty of the first female being to form a dwelling for her family, she is unprovided with wings—they would be an encumbrance to her, and it is even probable that their development might diminish her fecundity; but when the family has attained sufficient extent winged females are perfected, which, led by instinct, depart from the place of their birth, to disperse their progeny over the face of the earth; these are always so different in appearance, and vary so essentially in the anatomical structure of the thorax, that, knowing them to be of the same species, one would never imagine they were of the same sex.

In all probability, the expansion of the gall causes it to crack, or an entrance may be made by insectivorous birds or ants, wasps and other insects, which, attracted by or feeding upon Aphides, may gain access to the interior through the natural suture, and thus the winged specimens are enabled to escape from their prison and wing their way to other and distant districts to deposit eggs, which will again provide for a succession of wingless and viviparous females the ensuing spring. These helpless animals seem to require the protection of an artificial covering to guard them from the extremes of heat and cold, and unless the inner surface of the gall were kept moist, in the manner already alluded to, it is probable that

the sap would not flow, and these feeble creatures would all perish. In these cells one would have supposed they must rest secure, but such is not the case, for they are saved from the larvæ of Aphidivorous insects, such as the larvæ of the Ladybirds, Syrphidæ, &c., many of which I have found living amongst the Plant-lice in the galls, luxuriating upon their flocks, which seem scarcely to be diminished by the hourly drafts which are made upon them: this, however, is not actually the case, for a single larva of a Syrphus will often, before it arrives at maturity, entirely clear a gall of the Plant-lice.

I wish to repeat, that the Briosoma bursaria is a typical species of the genus; and if the nerving of the wings be compared with that of the Elm-tree-gall Aphis and the American Blight, it will be seen that it varies very materially, so that a careful observer could readily distinguish the first from either of the others, which are also easily separated by the form of the stigma.—*Ruricola.*

FAMILIAR BOTANY.

Morphology, No. VII.

(Continued from page 148.)

What is this mighty breath, ye sages! say,
That in a powerful language, seen, not heard,
Instructs us? —— What but God?
Inspiring God, who, boundless Spirit all,
And unremitting Energy, pervades,
Adjusts, sustains, and agitates the whole?
He censeless works alone, and yet alone
Seems not to work; with such perfection fram'd
Is this complex stupendous scheme of things.

If it is a fact almost surpassing man's powers of comprehension, that all the varied products of vegetation are but little changes in the proportions of the elementary matter that constitutes the fabric of plants—which fabric is, moreover, itself, for the greater part, a mere condensation of air—it is not less curious, though far more intelligible, that the different kinds of tissue which are gathered together into stems and leaves, and flowers and fruits, should themselves be but changes from one common form of tissue, notwithstanding the diversity of forms in which it finally appears.

If you boil a head of Asparagus, and then rub it in water in a dish, you will find that it separates into different parts, one being a kind of pulp, the other strings. The pulp consists of minute bladders; the strings are composed of fine threads of different kinds. Or, again, take a young shoot of the Elder-tree, and pound it in water; it, also, will separate into pulp and strings, the former consisting of bladders, and the latter of threads, as before. Such bladders and such threads are found in all plants, constitute what is named their tissue, and form the whole fabric of vegetation.

Nothing can be more different than the forms of tissue. The bladders are more or less round and brittle, constitute pulp, pith, cork, and such parts, and, from their appearance when cut across, are named *cellular tissue.* The threads are very long and tough, and some of them extremely curious, resembling little corkscrews of silver. A muslin handkerchief is composed of threads that are straight, extremely fine, and several inches long; such threads form wood, give toughness to all the parts of a plant, and are called *woody fibre.* If you snap the stalk of a Strawberry leaf, with a little care, you will find that it contains a fine cobweb-like substance in its interior; the parts that snap and cover up the cobweb are, first, a layer of cellular tissue, and next a coating of woody fibre, which guards the cobweb. The cobweb itself may, with gentleness and care, be pulled out to a considerable length, and will be found, when viewed against the light, to consist entirely of spiral threads of inconceivable fineness; such threads we name the *spiral vessels.* These kinds of tissue are all very different, not merely in form, but in the uses they are for; thus the cellular tissue is for digestion, the woody for strength and the conveyance of sap, the spiral for the passage of air. Yet they are all one, as may be demonstrated.

The Oak grows out of an Acorn, the Wheat from a grain of Corn, the Cocoa-nut tree from the contents of a hollow shell. The Oak, the Wheat, the Cocoa-tree, have both cellular, woody, and spiral tissue; but the Acorn, the Corn, and the shell have nothing but the cellular. It would therefore *seem* from this that the two others must be fashioned by the powerful hand of the Creator out of the cellular. But the Morphologist is not contented with an inference; he looks for proof.

Armed with a powerful microscope, keen knives, and yet keener eyes, he patiently watches the progress of development in the germinating embryo, and then he finds that some of the little bladders lengthen, thicken, and cluster together, till they cease to be bladders, and become long and delicate threads. He looks again, and lo! there are other cells, which also lengthen, but without becoming tougher, and gradually form on the inside of their thin transparent sides a spiral line, which applies its turns the one against the other, till at last a second shell, spiral and tough, though indescribably slender, is deposited within the first. The primitive bladder has, in truth, the double property of lengthening on the one hand, and of depositing matter, which is secreted all over its inside, in a spiral direction, or as a uniform varnish, or in a variously broken and interrupted layer.

Here, then, we have proof, irresistible and convincing, that the many textures of a plant consist of bladders, differently varied by the wondrous power of life. Unchanged, and in their primitive condition, these bladders form mucilages, Mushrooms, pith, pulp, and all the softer parts; lengthened out, and rendered tough by a smooth lining of matter secreted within them, they become wood, and the powerful net-work which holds together the leaf,

[illegible] Gardeners' Chronicle, vol. I., p. 85, and Royal Agric. Journal, vol. III., pt. 2.

still gives it force to resist the storm; or extended, and lined by a spiral thread deposited within them, they form the exact imitation of the breathing apparatus of insects, and those of man.

And thus does Nature simply work in the elementary construction of that which seems so wonderfully complicated a machine, the fabric of a tree. Three, or at the utmost four, air-like bodies are condensed into bladders, to which the power is given of secreting internally matter like themselves, and of assuming various forms at the bidding of the vital force. The bladders in their new shapes are compelled to arrange themselves in the endless forms that clothe the earth with a verdant mantle; and thus, and thus only, are provided the materials of the largest of the Kingdoms of Nature.

Untutored man looks on such things without seeing them; he is surrounded by silent prodigies more surprising than the wildest dreams of fancy; and he knows them not, or disbelieves. He is satisfied with results, and thinks not of their causes. It is only to the philosopher that are revealed the mighty secrets of the hidden places of the earth.—*R. E.*

THE ROSE-GARDEN.—No. VII.

(Continued from page 117.)

Plants which have been weak, sickly, and unfit to work the first season, will frequently break at several joints in the spring, beginning from the root; in this case, the converse of the habit of a healthy plant is exhibited, in the unhealthy the highest shoot is the weakest, in the vigorous the greatest power is displayed at the summit of the plant. When the weakness of a plant is determined, the whole of the buds should be allowed to push, in order to loosen the bark; when each push has produced two or three pair of leaves, the highest, which is in general weak, should be removed, the two next left to increase, and all below them stopped, only one or two pair of leaves being left to each, their final removal not taking place until the three upper shoots left to increase are become vigorous.

Insects.—In order to secure the shoots from the attacks of the caterpillar, it is necessary to look over them frequently, destroying slugs and snails also, as all of these do much injury—the first by eating the point of the shoot, on which it remains whilst there is food, twisting the end leaves together, and living on them—the others by eating through the shoot, frequently at its base, if not large and ripening.

Keeping shoots even, and removing thorns.—As soon as the spring-shoot is over, it will be well to look over the stocks, and wherever a single shoot be found which is running away from the others upon the same stem, it must be stopped by pinching off the extreme point, in order to bring the others up to it, that all the shoots may assimilate in size by the time they are to receive the bud. On the 1st of July, it will be well to remove the thorns from the places desired to bud upon. If this be delayed, the plant will have had no time to recover from any slight injury; and if omitted, there will be some trouble and inconvenience in placing the buds. A sufficiency of the shoot should be thus cleared, to allow of the ligature being bound around, without any thorn interfering with the operation.

Time of Budding.—It may be observed, that the growth of the wild Rose differs so much from that of most other plants, that shoots may be found to receive a bud at all seasons of the year. A plant budded on the 21st of October with a species not free growing, was the forwardest, out of fifty which had been budded the same autumn, to start vigorously in the following spring. If, therefore, an unexpected shoot break in a desirable place from a stem (already budded in August or before), use should be made of it without reference to the time of year.

From the beginning to the end of August is, perhaps the most certain time to bud with a dormant eye (*a l'œil dormant*), as the sap is then in full force, especially if the season be moist, after a drought. The passage of the sap, however, varies in different years, and the time to bud of course varies with it. The desideratum is, that the trees should be in full vigour, and the bark part with the utmost facility from the wood, showing a rich supply of sap below it. This is, in general, the case at the season before mentioned. A fall of rain should be taken advantage of, if possible; for, be it observed, that budding during a long drought would be labour entirely thrown away. If the season, therefore, advances without rain, and the sap in consequence be checked, the substitute (which, by the bye, is a poor one) of watering the roots of the stocks well for some days beforehand should be adopted; but, in the event of rain, the operations may be commenced the next day. Early in the morning, and late in the evening, are the best times to bud; and a cloudy atmosphere affords the most advantageous opportunity. Above all, a day having a dry northerly or easterly wind should be rejected, for great evaporation taking place at that time, the tender parts exposed to it are instantly dried up, and the work is frequently destroyed before it is completed.

It will be observed, that during wet weather plants increase in bulk, during hot weather in length; if, therefore, a long continuance of heat and drought take place (especially in a poor soil), after the working of a plant, the action of the sun, which drives the sap to the point of the shoot by contracting the bark, loosens the ligature, and the inserted eye frequently perishes. For this reason it is desirable to enter the buds as soon as each plant is forward enough to receive them. Stopping the end of the shoot may occasionally remedy the evil, by preventing an extension, and thus causing it to swell. When a slight or indeed heavy rain takes place just before the stocks are setting, the sap will be found in motion, and buds may be inserted with facility; but unless a continued supply follow, the juncture of the newly inserted bud with the stock will not take place, and failure may be expected.

Dormant and Pushing Buds.—The difference in England between a dormant and pushing-bud (*œil dormant* and *œil poussant*) is generally one of chance, and almost confined to free-growers. The time chosen to bud is commonly the end of July, or beginning of August; and if a bud springs, the branch is shortened, two or three buds only being left on the branch, (and these are pinched off, one by one, as the shoot advances:) these, of course, beyond the inserted bud, which thus has a chance of shooting strong enough to ripen before winter: if this be done, one bud should always be left (though nipped at the point to prevent its occupying the sap), as a security during winter, which would, otherwise be more likely to cut off the shoot, which has, as yet, but little strength. This lopping a branch, however, at a time when the sap is at its fullest, cannot but injure the root of the plant, by the temporary stagnation it causes.

Grafted and budded Roses of all sorts will be found to dwindle away, when the heads they carry have become weak and the bark of the stock set and hard for a whole season. On the transplantation of all worked Roses great care should be bestowed to secure the roots from injury, as well as to replace directly (rapid growing soils suffering less from temporary stagnation than delicate ones). The stock, in its natural state, will exist and recover, almost without a root, but it must be remembered that this pre-supposes it to have been healthy and vigorous, under which circumstances, when the top is cut off and the roots cut in, the vigour which is retained in the neck of the plant will make extraordinary exertions for its recovery; large shoots will be thrown out from its sides, and the activity of the plant will be rapidly restored; if, on the contrary, the stock be replanted with any shoots left upon it, this recovery will be neither so rapid nor so certain. Great attention is, therefore, necessary in pruning trees after transplantation, which operation should always be done with the object of promoting the speedy ascent of the sap and formation of fresh free-growing wood on the spot to which the plant has been removed. In direct opposition to this, many sorts of Roses, on their own bottoms, require lifting occasionally, to prevent the roots going too deep, and the flowers diminishing in quantity, as well as to divide the roots, remove the decayed parts, obtain offsets, &c.

In France, budding with a pushing eye takes place at the end of May, and is frequently used when, a few buds only being procurable of a certain desired species, it is an object to increase them as soon as possible; in this case, three or four natural buds should be left beyond that which has been inserted, and these should be taken away, as before mentioned, with the intervention of a week between each.

(To be continued.)

Home Correspondence.

Tank-Heating.—Permit me to make one or two observations upon the subject of tank-heating, of which I have now had some experience. My greenhouse is 45 feet long and 14 feet high, and therefore contains a considerable area. This I have succeeded in heating very perfectly, by means of the smallest size Rogers boiler communicating with a brick gutter cemented: the gutter is not divided, but passes round the house, obstruction to the entrance being avoided by carrying the water under the floor opposite the door, by means of a lead pipe which dips and rises on the other side to the same level; the water thus leaves the boiler, and passing once round the house re-enters the boiler. I conceive that this arrangement is to be preferred to the divided gutter, where the water-course is long, the water being less cooled than if it ran round the house and back again before it re-entered the boiler. You had some doubts as to the applicability of brick gutters with slate covering, to the case of greenhouses, fearing that the atmosphere might be too much charged with moisture. I can assure you that fear is quite groundless, as I find my house perfectly free from damp, and indeed the plants require watering now every other day, the soil becoming quite dry in that time; a moister state of the air may be maintained when proper, by raising two or three slates in different parts of the house. The slates I employ are a quarter of an inch thick, and are cemented to each other at the sides; this thickness adds to the strength, but I imagine, has the disadvantage of confining the heat longer than thinner slates would do, which might be equally well secured by cementing their edges, made to overlap. There is an appearance upon the surface of the water contained in these cemented gutters, which being a crisp scum and somewhat like a coating of ice, may have puzzled some of your readers who have seen it. I may mention that it is chalk, and that the water contained in a recently constructed cement tank is highly charged with lime; in fact, is pretty strong lime-water, feels soft to the fingers, and gives a bitter taste to the tongue; the carbonic acid gas contained in the air of the house, acts upon the surface of this lime-water, and converts it into carbonate of lime. I suppose that this solution of the cement is peculiar to recently constructed tanks, and such as have been made use of before the air had the opportunity of acting upon the surface, and converting it into carbonate of lime; and should the evil continue, I should be disposed to draw off all the water, and allow the tank to be exposed to the air for a few days. My gardener has been employing boiling hot water for the parts of my Mills' pits infested b

sow-bugs, and with very decided effect, those numerous and troublesome little pests yielding up their lives by thousands to this application.—*T. Harrold Fenn, Weyland, Suffolk.*

Pines.—I have lately seen some fine fruit from young plants, at Colney House, near Barnet. On Christmas week an Enville was cut there weighing 7 lbs. 4 ounces; a Queen, 4 lbs. 12 ounces; and a black Jamaica, 5 lbs. 3 ounces. Many more were cut previously of a similar size, but were not weighed. In the beginning of December an Enville was cut 6 lbs. 9 ounces; this was a curiosity in its way; three small fruit, each being perfect, grew out of the crown, and were all ripe at the same time with the principal fruit. Mr. John Fish, the gardener there, grows them almost entirely in loam from Colney Heath, using it as rough as possible. He attaches great importance to growing the plants very fast, and fruiting them when they are young.—*A Visitor.*

The Beefin Apple.—Being a native of Norfolk, I am well acquainted with our excellent Apple, the Beefin. This is frequently known by the names of Biffin and Beaufin; but Beefin is the true name, originating from its striking resemblance to a piece of raw beef.—*M. G.*

Gourds.—A correspondent some time since remarked that he had never seen the Potiron Jaune grown in England to anything like the size and perfection which he had witnessed in the north of France. In the year 1822, I grew in my garden at Stoke Newington, from seed which I had of the Society in Regent-street, a fruit which weighed 130 lbs., and which measured in circumference 5 feet 8½ inches. This I intended to exhibit at a meeting of the Society, but could not, at the time, find a convenient conveyance. After keeping it several weeks, till it began to decay at the part where it had rested upon the ground, it was placed upon the hall table as a curiosity, and was cut up and used, in lieu of Peas for soup, which was of a bright golden colour and excellent flavour.—*J. B. K. L.*

Excrescences on Oak.—"T. G. Clithero," at p. 22 of this year's *Chronicle*, appears to have misunderstood me on this subject, where I said the timber of trees having excrescences was generally shaky and worthless. "T. G." says, "it is of ten times more value, if not unsound, and that whatever may be the cause of the curliness, it has nothing to do with unsoundness." He says, further, "that such trees grow as vigorously as others, their neighbours." Trees may appear to grow vigorously, and yet be unsound in the inside. What I said was, that the trees (alluding to those growing in Porkington-park,) appeared to be of a great age, and showed symptoms of decay, from various causes, and that those that had been cut down were found to be decayed in the inside; namely, all the wood that had been formed previously to the commencement of the excrescences. I have lately seen many Oak-trees, including Pollards, covered with excrescences. The Pollards are all, more or less, decayed inside, some of them are quite hollow; but to look at their branches, they appear to be in vigorous growth. A person who has had much experience in working up such trees says, that if the trees are old he invariably finds the timber either decayed or beginning to decay. Hence it is only the curled excrescence that is of much value. He confirms what "T. G." says respecting its shrinking and requiring five or six years' seasoning, before being worked into furniture, &c., and says that it requires to be cut in a particular manner for such purposes, or it is of no value. The reason of curled wood of Oak shrinking, and requiring so long a time to season before it can be advantageously made use of, appears to be the premature decay of some of the annual shoots and buds, on account of their being crowded closely together; they are inclosed in the living wood, similar to the decayed branches sometimes inclosed in other timber; these make spaces in the wood like small holes and fissures, of a dark-brown colour. The excrescences are an after-growth, formed by the filaments or woody tissue from the numerous annual buds and shoots that grow, as it were, on the original wood, being obstructed by some cause in descending. Such curled wood recently formed, is generally sound to a considerable thickness, and it is only the curled wood that is valuable, and not the first-formed straight-grained timber. Such wood would be more valuable and more in demand, if cabinet-makers knew the proper way of cutting and seasoning it for their purposes, as it is the timber of such trees that is of little value. "T. G." is wrong when he says "the excrescences occur from a tendency the trees have to throw out roots from every part of the stem." He instances the roots, or protuberances that would be roots, in some kind of Apple-trees; but the excrescences on the Oak and Elm are very different from the knobs or burrs on some kind of Apples, which is an effort to make roots, but they cannot do this, except in a close, moist, atmosphere; the knobs on old Cherry or other trees not apt to emit roots, must arise from obstruction of the descending filaments. Protuberances of these, if of a large size, would probably be curled like the Oak and Elm; but the annual young shoots and buds on the Oak and Elm make no roots at all, except "T. G." designates the obstructed woody tissue roots, or the rudiments of roots; neither does the curliness penetrate into the previously-formed wood, but is evidently an excrescence formed upon, and after the original wood begins to decay in the inside, whether visible or not to outward appearance. All the trees having excrescences in Porkington Park, seem to be past their best, and, no doubt, beginning to decay inside; in many of them the decay is perfectly visible either at bottom, middle, or top; hence, when durable and profitable timber is required, such trees should be felled as soon as the excrescences make their appearance, except it is desirable in parks or pleasure-grounds to retain them for their singular appearance and the value of the curled wood.—*W. Billington.*

Durability of Oak-timber.—I fear that the beam found at Oswestry, and mentioned by Mr. Billington, (*Gardeners' Chronicle*, 1844, pp. 69 and 117), is not so old as he supposes. When reading that account, it struck me that the numerals were so given by him as to make it appear that they are the Arabic numerals now in use; and if so, it is highly improbable that the date really intended is 1035. If Arabic numerals were at all in use at that date, which I doubt, they must have been very rarely used. It is also highly improbable that the person who built the house, supposing the date to be 1035, should have been sufficiently acquainted with letters to be able to use them in this case, more especially as the Rev. T. Salway informs me that they are very perfectly formed. It should be remembered that Oswestry was upon a disturbed frontier, and also that grants of that early time are usually not dated, and that even William the Conqueror himself could not write. Mr. Salway tells me that he believes that the date was originally 1635, and that some person has altered it by cutting away the top of the 6. I believe, therefore, that the Oak-beam cannot be proved to be more than 209 years old, instead of 809; and this is of consequence, from an argument for the durability of Oak being derived from the former supposed date.—*Charles C. Babington.*

Garden Varnishes.—The composition described by "Devoniensis," at p. 301, 1843, is a very good one, and is used by the fishermen on the Norfolk coast to pay their stout calico-jackets with, thus making them waterproof. They add a little mutton suet. The mixture is as follows:—1 gallon of pale linseed-oil, 3*s.* 9*d.*, 3 oz. of sugar of lead, 3*d.*, 10½ oz. white resin, 1½*d.*, and ½ lb. mutton suet, 3*d.*—in all 4*s.* 4½*d.* the gallon. These simmered together will make a useful varnish, at a reasonable cost. The use of the sugar of lead is merely to dry the oil.—*Rambler.*

Miscellaneous.—*J. K.* suggests that it would be an advantage to country gardeners if gentlemen, instead of giving money prizes, were to offer rare plants as rewards at floral exhibitions. This, he imagines, would create a more general desire for fine flowers. For instance, he says, if a dozen of Verbenas in flower were given for a prize, it would encourage many to become florists, and thus strengthen the object of a society. A knowledge of the qualities of objects exhibited would likewise by this means be increased.——*Verax*, a known correspondent, in justice to Messrs. Youell and Co., states, that about this time last year he planted a few canes, had from them, which bore abundantly very large fruit, and continued bearing until the frost. He informs us that he had more this year, being so much delighted with the flavour, size, and long-continuance of bearing.——*J. P.* intimates that guano is an effectual destroyer of worms, as long as its influence lasts, and that by applying it frequently in small doses its action may be extended much. Being also beneficial in promoting growth, it is an important friend to the gardener.——*J. G.* informs us that he planted a few early Kidney Potatoes in an old Pine bed in a Vinery, about the beginning of December. He put about two feet of leaves in the bed, and covered the tubers about nine inches deep with soil. They came up very strong; but being far from the glass they became drawn. When they were about 18 inches high, he pinched about half an inch off the leading shoots of part of them, leaving a few untouched. Those that were stopped began in a few days to form Potatoes, but those that were not stopped produced only a bunch of fibres. Of the former a very fair crop is now ripening off, and our correspondent says that any kind of pit, however far from the glass, will answer the purpose under this treatment.——*R. P.* states that his Vines are subjected to the heat of a fruiting Pine-stove. Some of them are fruitful, others are not, although apparently producing equally luxuriant wood; they are planted outside, and introduced into the house by holes under the front lights. The first is a Black Hamburgh, with two branches; one branch, which produces thirty bunches, is trained up the rafter, the other runs along the inner side of the front lights, until it reaches the adjoining rafter, up which it is also trained, but it produces no fruit. The White Frontignan is trained up the next rafter; it bears eighty bunches, while the Black Muscat, trained along the front, and taken up the adjoining rafter, is perfectly unproductive. Next follows a Black Hamburgh, that was cut down last year; it is trained in the same way, and bears a good crop on the branch taken up the rafter; they are all pruned on the spur system. [It appears that the upright shoots are fruitful, whilst those trained horizontally are unfruitful. The former should be waved. Has any one seen a similar case?]——*A Paddy*, speaking of Heath edgings, observes, that Heath will grow in any ordinary garden-soil, and that it may be removed at any season. He informs us that he has pulled up young plants from their natural bed in all seasons, and larger plants in flower, all of which succeeded perfectly in the garden; he states that the flowers are as brilliant as if they were produced on their native wilds.

Societies.

BOTANICAL SOCIETY OF LONDON.

Feb. 2.—A. Gerard, Esq., in the chair. Various donations to the Library and Herbarium were announced, including 44 new species of Mosses, collected at Swan River by Mr. J. Drummond.—Read, the commencement of a paper by E. Lees, Esq., being A Synoptical View of the British Fruticose Rubi, arranged in groups, with explanatory remarks. The groups into which Mr. Lees unites the species have been already reported in this journal, in a paper read before the Society last year. The list of species will shortly be published in a new Catalogue of British plants, now in the press, for the Botanical Society of London. The following explanations in the words of the author will sufficiently show that this arrangement has not been founded upon any brief or superficial study of his subject:—"Having previously designated the general groups into which the British Fruticose Rubi are divisible, I now proceed to attempt the more difficult task of describing the species in each group, and tracing them in succession in a synoptical form. In doing this, as I must necessarily propose some alterations, it is advisable that the candid and inquiring Botanist should be informed as to the principles I have kept in view. In the first place, then, I have desired to make no innovation but what seemed imperatively required for correct elucidation; and have, therefore, made every effort to profit by the labours of preceding eminent Botanists who have particularly studied the Rubi, as Sir J. E. Smith, Drs. Weihe and Nees von Esenbeck, Mr. Borrer, and Professor Lindley. But, secondly, I have observed with the eye of an original explorer, tracing every form that appeared to me different, without reference to the ideas of other Botanists. And, thirdly, having observed the same plants in a living state for several successive years, I have collated and revised my original observations, sketched every apparent species, and compared them again and again with the figures, descriptions, and named specimens of Botanists of authority. Thus, I have been enabled, in a great degree, to understand the forms to which particular names have been assigned, and to test their propriety by my own experience; I trust, therefore, that I shall not be considered guilty of assumption when I may differ from others, being only anxious for the nearest approximation to correctness. It is unnecessary for me to go into the question as to what constitutes a species in this genus; for, as I have before hinted, it is not unlikely that the forms in every 'group' may be really only varieties sporting from a normal form, and into each other; but, if Botany be a science of discrimination, it is at any rate convenient to name every remarkable form as a species or sub-species; since, otherwise, minor variations can scarcely be distinguished, or must be placed in the same rank with more important deviations of structure. Indeed, Nees von Esenbeck, one of the authors of the elaborate 'Rubi Germanici,' has well remarked, in a letter to the Rev. Mr. Leighton, in the 'Shropshire Flora,'—'I am not of opinion that all the forms proposed by my friend Mr. Weihe as species are to be considered as such; but, in my opinion, it is absolutely necessary to look for the greatest number of forms which present themselves to us in the genus, before attempting to judge of species, and fixing their limits. I can scarcely tell which is most perplexing in the path of our science, whether,—with Mr. Weihe, to distinguish as species every form of Bramble that presents itself to our view,—or, with Mr. Koch, to consider all as modifications of one only. In this case, I do not doubt that these are matters purely of observation, and that the faithful observer of Nature will find that the truth really lies between the two extremes.'"

LINNÆAN SOCIETY.

March 5.—Edward Forster, Esq., in the chair. Dr. W. H. Milne, of Nottingham, was elected a Fellow.—Mr. T. Hall presented, through Dr. W. H. Brown, a specimen of the eight-banded Armadillo.—Sir W. J. Hooker presented specimens of above 50 species of fruits, the greater part new to the Society's collection, including many rare Coniferæ, from North America and Australia; the flowering scapes and portions of the stems of two species of Xanthorrhœa; the root of a species of Ebony from Madagascar; a specimen of the inner Bark and section of the stem of the Lace-bark tree, &c.—Miss Potts, of Chester, presented specimens of Lepidium latifolium, and of a variety of Erodium cicutarium.—The stem of a Xanthorrhœa was presented by T. W. Mann, Esq.—A paper was read from C. C. Babington, Esq., on the Spiranthes gemmipara. This plant is the Neottia gemmipara of Smith, and was named and figured by him in English Botany from a single specimen found by Mr. Drummond, at Bearhaven, Castleton, in Ireland. During the late meeting of the British Association, Mr. Babington visited the spot where the original specimen was obtained, and found about twelve specimens in flower. The plant was confined to a few spots near the sea-shore, occurring on the drier parts of boggy fields. This species differs considerably from the others of the genus, but more especially in the connection of all the sepals with the two upper petals. The flowers are arranged in three spiral lines, forming a dense spike. The Hybernacula, described in English Botany, are not constant. Two papers were read from W. Griffith, Esq. The first was a description of Cytinus dioicus. It is a native of the Cape, and found parasitic upon Eriocephalus racemosus. It does not, however, injure the plants on which it grows. The second paper was a description of the genus Mystropetalon, which had been referred by Mr. Harvey to the Rhizanths, and to the order Balanophoreæ. The author considered it to be nearly allied to Cynomorium, and that these two genera form a peculiar family of a very distinct kind.

ENTOMOLOGICAL SOCIETY.

Mar. 4.—George Newport, Esq., in the chair. The president announced that the subjects for Mr. Hope's two prizes of five guineas each were,—First, the Natural History of Vesicatory Insects, including an account of all that had been used for the purposes of vesication, with descriptions of the species; and also a chemical analysis of their secretions. Second, the Natural History of the genus Stylops.—Mr. Stephens exhibited several specimens of rare insects, and amongst others a variety of Meloina Euphorbiæ, taken a fortnight earlier than usual for this species.—Mr. Westwood exhibited a variety of Acacia Chen, with larger wings and antennæ than usual; also the cocoons of a species of Ichneumon, attached to a piece of

cord, and from which the insects escaped at either end.—Mr. Doubleday exhibited a new species of Polyommatus, from the Missouri.—Four species of Papilio, from Assam, were exhibited, two were new, and the other two had not yet been figured.—Mr. Westwood exhibited specimens of an orthopterous insect, in which the leg had been reproduced after having been broken off. The new leg was distinguished from the others by its smaller size, and the absence of the warty projections which exist on the old ones. He believed that no reproduction of parts took place in those insects which undergo what is called perfect metamorphosis. The antennæ of the larvæ of Raphidia had been reproduced, but this genus must be looked upon as having an imperfect metamorphosis, as the pupa moved when touched, some days before it passed into the imago state. Mr. Westwood also read a paper on the economy of the genus Palmon. This genus belonged to the Ichneumonidæ, and a species of it had been described by an anonymous writer in the "Entomological Magazine," as attacking the eggs of a species of Mantis. The eggs of the Mantis are covered over with a woolly case, which however did not prevent the Palmon from depositing its ova in the case. This fact the author considered was opposed to the opinion expressed by Mr. Curtis in his paper on the cocoons of the larvæ of Dieloceras Ellisii, which he supposed were covered with wool to prevent the attacks of the Ichneumonidæ. A discussion followed the reading this paper, in the course of which the President observed that he believed the law of the reproduction of parts was the same in all the Articulata. The reason why the limbs of the larvæ of insects undergoing a perfect metamorphosis were not reproduced was, that they died of hæmorrhage from the wound. He referred to Mr. R. Goodsir's observations on the reproduction of the legs of the Crustacea, which Mr. Goodsir had traced to the existence of a gland for the especial purpose. He hoped, however, those observations would be repeated. In the course of the discussion the curious fact was stated that sometimes insects belonging to winged genera failed to develop their wings, and were wingless, whilst sometimes wingless species, of which the too common Cimex lectularia (Bug) was an example, took to themselves wings and begun to fly.

Reviews.

A History of British Fossil Mammalia and Birds has been commenced in monthly Parts by Prof. Owen. The Author proposes "to give a description of the most instructive and remarkable remains of the extinct Mammals and Birds of the British islands; to define their generic and specific characters, so far as they are exhibited by such remains; to deduce therefrom, by physiological comparisons, the habits of the species when living; to trace out their zoological affinities, and to indicate their geological relations, and the order of their occurrence in the fossiliferous strata of Great Britain." We cannot doubt that this will be an important publication, and most acceptable to Geologists. The first Number is executed in the same beautiful manner as Mr. Van Voorst's other works, and the name of Prof. Owen is the best of all guarantees for the value of the information it contains.

A Descriptive List of Perennial Grass-Seeds, by J. Sutton and Sons, Reading, is a single sheet of paper setting forth the kinds of soil best suited for the Grasses and other plants employed in forming permanent pasture artificially. It will be found useful, and may be had upon application to the authors.

A Practical Treatise on Brewing. By William Black. 3d Edition. 8vo. Longmans.

This is a complete account of the process of brewing in the large way, with directions for conducting the operation properly in small households. Among the novel views of the author, we may more particularly mention his opinion, that the quality of malt depends on the soil on which the Barley is grown; and that the bad quality of beer, although no doubt owing very often to other causes, is frequently caused by the unsuspected agency of galvanic influence. For the evidence adduced in support of these views, we must refer the reader to the work itself.

The Natural History of the County of Stafford. By Robert Garner, F.L.S. London. Van Voorst.

There is nothing more likely to excite a taste for the study of natural history than well-written, interesting accounts of local objects. However important lists of plants and animals, and technical descriptions of strata, &c., may be to the advancement of science, they are not things that interest the feelings, and induce persons to embark in their study. Up to this time there have been but few books published on local natural history, embracing all the objects of interest in a particular district. This may have arisen from the want of persons, with time and leisure, who could accomplish such a task. It has, however, been done in the volume before us for the county of Stafford, by Mr. Garner; and few persons could have been found more competent to the task.

The work commences with some history of the eminent men who have been born, or have lived, in the county of Stafford. The geography, meteorology, antiquities, geology, zoology, and botany of the county, are treated of in successive chapters. All these subjects are developed at some length, and the zoological and botanical departments contain general observations of an introductory nature, that will make the volume serve, in some measure, as a text-book for the study of animals and plants. We cannot, however, commend Mr. Garner for arranging his plants according to the Linnean system. None of the Floras of the whole island are so arranged now, and it will soon be more calculated to puzzle than to assist the student in botany. The Flora of Staffordshire is somewhat northern and subalpine, the surface of the county lying between 700 and 1500 feet above the level of the sea. It is quite deficient in many of the plants very common in the south of England and near London, and comparatively few of the plants of the chalk are found, as Stafford consists principally of the new red sandstone. In addition to the flowering plants, there are lists of the Cryptogamia, which seem to be tolerably full, and much more complete than such lists usually are.

There are interesting accounts of the lead, copper, and coal mines, and also of the Staffordshire potteries. A memoir is added of that extraordinary man Josiah Wedgwood, to whom his country and the world are so much indebted, for extending and beautifying the art of pottery. He was the son of a potter, the youngest of 13 children, and at 11 years old begun to work at his father's business. He was, however, obliged to give up, in consequence of a lameness. In spite, however, of all these difficulties, he by his genius and perseverance obtained that wealth and position which are well known to all.

The work is illustrated with a number of engravings of antiquities, trees, animals, and other objects of interest, and we can but recommend the volume to those who take a general interest in natural history, and especially those who are living in the county of Stafford.—*L. E.*

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

Saxifraga ciliata. Fringed Saxifrage. (*Hardy Perennial.*) Saxifrageæ. Decandria Digynia.—This plant, of the section Bergenia, and very nearly allied to S. ligulata, is like that species a native of the mountains of Northern India. Dr. Royle speaks of it thus:—"I have had some difficulty in naming this plant, as the published descriptions, as well as the distributed specimens of Wall. Cat. 4193. and figures of S. ligulata, to which it is most nearly allied, do not correspond with one another; indeed, two distinct species pass under that name. The plant, S. ciliata, is found on the Mussooree and Sucn Range, at lower elevations than S. ligulata." The plant in the garden of the Horticultural Society was raised from seeds sent under the name of S. ciliata, from the Botanical Garden of Saharunpur. We must remark that Dr. Wallich has a second S. ciliata from India; the latter being S. imbricata of Royle. This is a robust hardy perennial, requiring the same soil and treatment as S. crassifolia; but when planted in the open border it must not have a situation which is damp in winter or fully exposed to the sun in summer. It is easily increased by dividing the old plants, or by seeds, which should be sown, when ripe, in pots filled with sandy peat and a small portion of loam. It flowers about May, in the open border. —*Botanical Register.*

Nelumbium Caspicum. Caspian Nelumbium. (*Stove Aquatic.*) Nelumbiaceæ. Polyadelphia Polygynia.—We are happy to have an opportunity of publishing this, not only for its own sake, but because it affords an opportunity of pointing out the true distinction between the Caspian and Indian Nelumbia. According to M. De Candolle all the Nelumbia found in various parts of Asia are varieties of one species, and this opinion is generally adopted. It is, however, difficult to believe that the deep red Nelumbium of India, with very sharp-pointed petals, such as is figured in the "Botanical Magazine" t. 3976, and elsewhere, can be the same with the blunt-petalled white-flowered plant "found at the mouth of the Volga, near Astrachan, in a part of the river called Tschulpan, amongst reeds intermixed with Nymphæas and Trapa," which, according to Messrs. Fischer and Steven, is the locality of this plant. M. De Candolle indeed suspected that it must be different, but he did not remark in the dried specimens examined by him any character beyond the bluntness of the petals and their general uniformity in size, and upon that distinction he was unwilling to rely. The true difference seems to consist in the very small number of carpels, which do not appear to exceed nine, while in the great Indian species they are as numerous as thirty or thirty-three. Speaking of N. speciosum and its supposed varieties, Dr. Roxburgh writes as follows:—"I have met with only two sorts on the coast of Coromandel, one with rose-coloured flowers, the other with flowers perfectly white, and since that time a third variety has been brought from China with smaller rosy flowers. They grow in such sweet water lakes, &c., as do not dry up during the driest season, and, on the coast, flower all the year round. In Bengal they flower during the hot season, April, May, and June, and ripen their seed about the close of the rains. In China there is a still more beautiful bright crimson variety, which they call Hung-lin; I have hitherto only seen a drawing of it. The white Nelumbium differs in few respects from the red one, and may be considered as only a variety of it. The tender shoots of the roots between the joints of both sorts are eaten by the natives, either simply boiled or in their curries. The seeds are eaten raw, roasted, or boiled. The leaves are used to eat off instead of plates. These holy and beautiful plants are often met with in the religious ceremonies of the Hindoos under their Sanscrit name *Padma*." It is a stove aquatic, requiring to be kept dry during winter. Before putting it into the water, which ought to be done about the beginning of February, it should be repotted in sandy loam mixed with pieces of sandstone, to act on the same principle as drainage, for the water in which it is grown requires to be renewed once or twice a week, and should never be allowed (especially in summer) to be below 60°. About the end of October, when the leaves begin to decay, the pot should be lifted out of the water and dried off gradually. As the soil becomes dry it will crack or leave the sides of the pot, which should be filled up with sand, in order to cover many roots that would otherwise be exposed.—*Botanical Register.*

Miscellaneous.

Age and Extraordinary Size of an Oak.—At about 6 miles W.S.W. of Saintes (in the Lower Charente), near the road to Cosnes, stands an old Oak-tree, in the large court of a modern mansion, which still promises to live many centuries, if the axe of some Vandal does not cut it down. The following are the proportions of this king of the forests of France, and probably of all Europe:—

Diameter of the trunk at the ground	from 9 to 10 yards
" At the height of a man	6½ to 7½
" At the base of the principal branches	1 to 2
" Of the whole head	40 to 43
The height of the trunk	6
" The general height of the tree	23

A room has been cut out of the dead wood of the interior of the trunk, measuring from 9 to 12 feet in diameter, and 9 ft. high, and they have cut a circular seat out of the solid wood. They put a round table in the middle when it is wanted, round which twelve guests can sit. A door and a window admit daylight into this new sort of dining-room, which is adorned by a living carpet of Ferns, Fungi, Lichens, &c. Upon a plate of wood taken from the trunk, about the height of the door, 200 concentric annual rings have been counted, whence it results, in taking a horizontal radius from the exterior circumference to the centre of the Oak, that there must have been from 1800 to 2000 of these rings, which makes its age nearly 2000 years. — *Annales de la Société d'Agriculture de la Rochelle.*

An Economical Polish Beverage.—Into sixty quarts of water put three ounces of Elder flowers, five pounds of common brown sugar, one quart of vinegar, and one of brandy; infuse them for three days, stirring them once every day. This beverage, which is mentioned in the "Agricultural Journal of Aix," is quite as agreeable as beer, and costs ten times less.—*Rev. Hort.*, 1843, p. 468.

Tea in India.—The Tea plantation at Kaola Ghir, on the western branch of the Tonse Canal, is, perhaps, the most interesting of all the symptoms of slowly returning animation in the Dhoon. There are to be seen 5000 vigorous plants of the shrub, thriving with a luxuriance unequalled, we were assured by the Malli, Cheyt Ram, and the Chowdrie of the Botanic Gardens, in this neighbourhood, Nanuck, unequalled in any other garden in the country. Many of the plants had blossoms and seeds upon them, and there seems no limit to the extent to which these plantations may be carried within half a dozen years. The increase, this year alone, at Kaola Ghir, by Dr. Jameson's orders, exceeds 3000 plants, and next year it might be 20,000! The best plants are raised from seeds, layering appearing not to be so quick nor so good a process; and these seedlings produce in the third year, a few even in the second, a large crop of seeds, which of course may be employed in extending the plantations. In 20 years, the entire Tea market of the world might be furnished from the Dhoon and similar Indian localities."—*The Hills*, an Indian Paper.

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSES, CONSERVATORIES, &c.

Keep up a moist heat of 75° or 80°, and let the house be rather close, in order to encourage newly-potted plants. Proceed with potting the different tribes as before mentioned; watch carefully over seedlings, and get in cuttings of those plants you wish to increase as early as possible. Now is the best time to strike cuttings.

Conservatory.—Climbers will now begin to spread over the house, and will require particular care in training them regularly at first. Stephanotus floribundus seems rather more hardy than Passiflora Loudoni: both survived in the conservatory here, this winter, in a temperature that averaged 45°; they are now beginning to grow freely. Little syringing should be done here, on account of the bloom; water must therefore be poured on the paths, and any spare places, to keep the atmosphere moist and cool. See that insects are kept down, and that plants have sufficient room. Specimen plants are easily injured at this time, if they are crowded together; all the plants brought in for the sake of their flowers only should be removed as soon as they are out of bloom.

Greenhouse.—Some of the more hardy and common plants in this house might now be turned out to some sheltered place, in order to give more room to the finer kinds. Young plants in small pots might now be potted on the one-shift system; but for this, it is essential that their roots are not much matted, and that they are in a growing state. The only disadvantage in this system is, that after a few years the soil will subside too much in the pot, and many delicate plants will not bear the pots to be filled up again. The best remedy against this, is to place an inverted pot over the drainage, as is often done for Orchidaceæ, and to have it so adjusted, that when you place the small ball on the bottom of it, the top of the ball will be level with the top of the large pot. A small Heath thus treated may safely be trusted in the largest pot: the collar of the plant always remains at the same level at which it is first placed.

Forcing-pits.—Keep every part of these pits full of plants, cuttings, &c.; any plant that can be forced into flower during spring is desirable. The Glycine sinensis is one of the easiest to force in a heat of 55° to 60°; we have it now beautifully in bloom. All the species of Jasmine force well; if they are kept under-potted, and their young wood is constantly stopped in the growing season, they form loose bushes, and give up their climbing habit when they are more manageable for forcing. Honeysuckles might doubtless be treated in the same way. All American plants require large quantities of water when forced. Introduce dry bulbs of sorts to succeed Gloxinias and Achimenes, and sow a few seeds of Balsams, Coxcombs, Browallias, Thunbergias, &c.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

The weather has been so exceedingly precarious of late that it is doubtful whether many of the operations already recommended have been performed; therefore look back to former calendars, and bring the work up as expeditiously as possible. Worms are very troublesome this showery weather, but they may be kept in check by watering the turf occasionally with lime-water made from stone lime, or they may be brought to the surface of the ground, and then removed by hand, by watering with a weak solution of corrosive sublimate. The best plan to dissolve this mineral poison is to add its weight of spirits of salts to it. Attend to mowing, sweeping, and everything that tends to promote neatness. Vacant beds in the Flower-Garden will be benefited by being dug over again when they are dry.

Shrubbery.—If it is intended to make any addition of new shrubs or trees in this department they should be got in immediately. Paulownia imperialis is a noble plant, if for its leaves only, and should be planted on every lawn; it will require protection until the stem gets woody, but after that it will probably stand as well as Catalpa syringæfolia. Araucaria imbricata is one of the noblest plants we have, and many of the Cedars, Pinuses, and Cypresses—to say nothing of Magnolias—are very beautiful. Continue the covering of tender plants for some time longer. Pinuses suffer more from the destruction of their early spring growths than from any other cause; therefore, endeavour to check them by admitting a current of cold air from the north side, and by keeping the plants shaded on sunny days.

Pits and Frames.—Among the first things to be attended to, especially where a large stock is required for flower-garden decoration, is the propagation of Chrysanthemums. Among the new ones which bloomed with me last year, may be mentioned Bijou, Arago, Grand Napoleon, Casimir Perier, Demosthenes, Julius Cæsar, Abelard, Ivanhoe, Minerva, Theresa, Marie and Phidias. Several of these are seedlings sent out for the first time last season by Messrs. Chandler, and are really excellent. Pot Tuberoses in 48s. in turfy soil, and place them in a gentle warmth until they begin to grow. They are useful for setting among plants near the windows, or for the decoration of the hall or drawing-room.—*W. F. A.*

III.—FLORISTS' FLOWERS.

Auriculas.—Another class of these flowers, styled Alpines, have made great advances in public favour of late. They are selfs, of all shades, from light pink and grey to dark crimson and deep purple, the eye or centre of the flower being yellow. Joined to extreme hardiness and beauty, they likewise used profusely. It

to dangerous to grow them in the vicinity of Auriculas with white grounds, if seed is an object, as the pollinia bee, particularly, will carry the farina from one to the other, and thus "masterfize" the ensuing crop of seedlings. They do not appear to be so susceptible of wet as the Auricula, and certainly are not so fantastic as to situation, flowering and flourishing almost anywhere. They are usually exhibited at spring shows, and cannot be too strongly recommended to the admirer of early flowers. Plants in frames must be watched in rainy weather, taking care that they have no drip; should this be the case, the laps must be pattied the first fine day.

Polyanthuses are now throwing out fibres round the neck of the plant, and growing fast. If increase is more an object than blooming, they may be parted to advantage now. The breed of this class of Florists' flowers requires improvement, and has made little progress during the past twenty years than any of the others.

Hedges ought to be protected from heavy soaking rains, as well as sharp frosty winds, which we may yet expect and the directions given in previous Calendars must be strictly attended to

Carnations.—From correspondents in various quarters I learn that there are great quantities of seedlings throughout the country; and as cross breeding is now better understood and acted upon than formerly, we may confidently expect some valuable additions to this deservedly popular flower

Ranunculuses.—Since beds have been planted we have had heavy rain; they should be protected with mats, as the roots are susceptible of frost when swelling, which often occurs after much rain at this time of the year. Keep seed-pans moderately moist.

Dahlia cuttings, that are rooted, may be potted off in light vegetable or leaf-soil, and put in close frames till they get fresh hold.

Pansies.—Young plants put out in beds last autumn will flower better than those planted in spring. Where additions are requisite, they should be made now, taking care in the purchase of them that you get the roundest flowers, with the colours as well defined as possible, the smoother and thicker the petal the better, and the ground or body colour of one shade, and perfectly clear; bearing in mind that white tinged with yellow, or yellow stained with orange, will not now do.—*J. F. W.*

IV.—PINERIES, VINERIES, &c

Pinery.—The plants in fruit may now have an atmosphere of 70° by night, and 75° by day. Give air when at 85°, and shut up at 90°, dewing the plants directly after with a fine-rosed syringe Sprinkle the plants lately potted, morning and evening, and continue to shade those that have been disrooted

Vinery.—Look over the earliest Grapes again, to see if any of the bunches are too thick, in which case, remove as many berries as is necessary, to give room for those that are left to swell without pressing against each other. It is necessary that syringing should be discontinued whenever the fruit begins to ripen; a drier atmosphere and more air will assist in giving it flavour and colour Attend well to the stopping and tying of the shoots in the second house. The late Vines will now be swelling their buds, and where there are long rods of last year's growth, bend them so as to have the lowest buds on the shoots considerably higher in the house than those near the points, and as the lowest buds break, keep raising the shoot gradually till all are broken.

Peach-house.—In thinning finally the fruit on the trees in the first-house, it will be proper to leave only one fruit upon a shoot of last year's growth (excepting where very strong) if the crop has set well and there is sufficient choice; but in thinning Peaches much depends on the crop being regular over the tree and the degree of vigour the tree may possess. One good fruit in a square foot would be sufficient for a tree in a medium state as to vigour, but more than this should be left till after the stoning. Weak branches should not be allowed to bear any fruit. If the fruit in the second house has set too thick, it will now require a partial thinning. Tie in the shoots in good time, and keep the syringe in use twice a day, and few insects will trouble you.

Cherry House.—Where the fruit is swelling keep the night temperature at 55° or 57°. With sunshine give air early shut up at 70°, and syringe immediately. Be careful to destroy all insects before the fruit begins to ripen, as you cannot syringe or fumigate afterwards.

Fig-house.—The Figs now ripening should be kept dry, and as they are liable to red spiders, use flower of sulphur on the foliage till you can resume the use of the syringe It is hardly necessary to say that those plants in pots that have much fruit upon them, should be assisted with liquid manure.

Strawberries.—The whole of the plants in pots for forcing would be benefited by a top dressing of some rich soil, or very rotten dung, and if they are under cover, they will occasionally require watering with liquid manure. Keep those now swelling off their crop in the houses free from insects, and bring in a succession once a fortnight.—*G. F.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Apricots and Peaches.—Proceed with the pruning and nailing of these as expeditiously as the weather will permit. If cut too soon, an access will be given to the frost, which will induce gum and canker in unfavourable situations. Daub all wounds, especially large ones, with thick paint Anoint Peaches with a mixture of clay, soot, sulphur and lime, adding soft soap and tobacco-juice, if you think necessary. The great use of such painting is to cover, and thus prevent the hatching of the eggs of insects For this purpose nothing is better than pure clay, well wrought up; soot and sulphur, if they do not nourish the buds, keep off birds; and lime gives the mixture a lighter appearance, than if soot alone were used, which helps to keep the shoots in a more equal temperature, by day and night

Cauliflower.—Sow in a slight hotbed for succession It is best to sow little and often A regular supply is thus obtained, and no superabundance.

Celery.—Sow in a slight hotbed, or under a hand light Prick out in pots what was previously sown

Tomatoes and Capsicums.—Sow in heat to get them forward, as otherwise they do no good in unfavourable places

Herbs.—Prepare for transplanting those where necessary, and get ready ground for annual sorts. Above all, forget not Parsley, and plenty of it.

Onions, Carrots, &c.—Prepare the ground for at least partial sowings of these crops. Those having wet stiff soils, must watch their chance.

Cucumbers.—Keep up the temperature; sprinkle the sides of your pit, or frame, after a sowing-day; stop, peg, or tie down shoots, impregnate fruit-blossoms as they appear, as the fruit swells faster in consequence.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—Attend to the directions given in preceding Nos., and proceed with the same work where it is not finished

Coppice.—Proceed with what has been previously recommended to be done here

Young Plantations.—Continue to put the fences in good order Cut and plash hedges, where that has not been done, as directed last week, and attend to what has formerly been stated under this head

Hedge rows.—Continue to plant and train young trees, repair and make new fences where they are required, secure trees from being injured by cattle, and protect newly-planted ones from strong winds.

Nursery Work.—From the continued unfavourable state of the weather, little can be done in this department Thin out the strongest side-branches where they are too numerous, and train young plants to one upright leader When the weather becomes milder, digging, planting, or sowing will be performed with more advantage than when the ground is wet and not in a proper state.—*W. M.*

VII.—COTTAGERS' CALENDAR.

As the season for grafting is at hand, the appearance of Thorn hedges may be much improved by grafting the sparish and other varieties on the top shoots. These should be allowed to grow up at different distances along the hedge, which should be regulated according to the size of the garden, and the taste of the occupier. A few hardy Roses may also be planted in the hedge, and trained in it. When these are in bloom, the blossoms projecting a little out from the hedge, only appear, and render it very ornamental. Some of the Roses might also be budded on tall shoots above the top of the hedge as Standards.

Vegetables.—This is an important time for getting in crops of several kinds; ground should be in readiness for Onions, Carrots, &c., which should be sown in drills as soon as the weather will permit. Of the former, the Strasburgh and James's keeping are good kinds. Make up deficiencies in Cabbage-rows, and sow a small patch for succession in a warm border. The Vanack is as profitable a kind as any. Of Potatoes a few of the Ash-leaved Kidney may be planted for an early crop.

Fruit.—See that all Standards are now pruned, and that the training of wall-trees is finished; this is a good time for grafting Apples, Pears, &c

Flowers.—As bulbs are all above ground, flower-borders may now be forked up, giving them a dressing of leaf mould or rotten dung. Herbaceous plants that are spreading too much should be divided, so as to occupy less room. Everything about the cottage should be trimmed up, and kept neat, as this is always a mark of taste and industry.—*Mr H.*

State of the Weather at Chiswick during the last 18 years, for the ensuing Week ending March 25, 1844

Mar.	Aver Highest Temp	Aver Lowest Temp	Mean Temp	No. of Years in which it Rained	Greatest quantity of Rain	Prevailing Winds						
						M	M	A	A	M	M	A

12th Very cloudy at noon boisterous, dark and stormy, with sleet, clear
13th Clear with slight frost; dark clouds clear at night
14th Uniformly overcast; rain, dense fog in afternoon rain at night
Mean temperature of the week, 1 8 deg below the average

Notices to Correspondents.

MR. PAXTON'S COTTAGER'S CALENDAR.—At the earnest solicitation of many of our Subscribers, we have determined on again reprinting *Mr.* Paxton's "Cottager's Calendar," in the form of a small volume, for general distribution, priced *3d* each copy It may be ordered of all booksellers. Gentlemen wishing to *distribute copies* among their cottage tenantry, may have them *delivered in any part of London*, by remitting a post-office order to this office, at the rate of *5s.* for every 25 copies.

APRICOTS.—*T Barnes.*—The Moorpark is one of the best Apricots for a south wall.‡

ASPARAGUS.—*Omega.*—Your plan of proceeding with the land to be converted into a garden, is unexceptionable; but there ought not to be any need of guano for the Potato crop. We should avoid that expense. In cultivating Asparagus we advise you to observe, as nearly as you can, the method employed in Biscay, as described by Capt Churchill at p 187, for 1842 But you may employ guano with advantage, instead of the Spanish manure, provided you mix it with an abundance of soil, or with common stable manure. Potter's guano or superphosphate of lime may be given afterwards, when the plants are in full growth. The grand point with Asparagus is to get the summer growth excessively strong the spring shoots will be large in proportion. We should be never satisfied with Asparagus till its summer shoots were at least 6 or 7 feet high. In planting Sea Kale you have nothing to do but get two year old plants, manure them richly, adding a good dressing of salt, and cut them every other year If you cut them every year you will weaken the shoots too much.——*C J.*—When your Asparagus makes its summer-shoot, give the beds weekly a dressing of salt and guano, dissolved in water, at the rate of ½ a cwt of salt, and the same quantity of guano per acre, and continue the dose for six weeks Gas-water, or sulphate of ammonia, will kill Moss, and make Grass grow, apply them in April. Potter's guano and superphosphate of lime have both an extraordinary effect on Asparagus, but we do not know that they will kill Moss on Grass land

AVIARIES.—*M E* inquires what birds would do best together in a garden aviary 17 feet by 12 Perhaps some correspondent will say. Nothing will do better for warming it than passing a couple of hot-water iron pipes through it; which may be heated by such a small boiler as Stephenson's There is a single white Hepatica, but we are unacquainted with a double white

BOOKS.—*A G.*—Lyell's Geology, unless you should prefer Mr. Ansted's, now in course of publication.

CHARCOAL.—*T B.*—Charcoal having been found not to disagree with plants of various kinds to which it has been applied as a manure, its introduction into compost for the growth of Cucumbers is worthy of trial ‖

COMPOST FOR CARNATIONS.—*A Beginner.*—Carnations require a light rich soil, consisting of turfy loam, well-rotted hotbed manure, with a portion of leaf mould, and a little grit, or coarse sand. Broken pots form the best material for drainage *

COVERINGS FOR FRAMES.—*R D B* states that he has tried the composition recommended at page 691 of last year's *Chronicle*, and although he followed the directions exactly, he found it required a long time to dry. We have communicated with "M E. H" on the subject, who says he did not experience any difficulty in this respect; that his covering, which is 20 ft. long and 10 ft. wide, was coated with the preparation one day, and was dry enough for fixing on the roller and putting in its place the day following He cannot account for "R. W. B 's" want of success, unless it was owing, perhaps, to a difference in the quality of the materials employed. The only remedy he thinks, in case of "R. W. B." making another trial, would be to add a small quantity of litharge, such as painters use for drying their paint, and no doubt it would have the desired effect.

CUCUMBERS.—*A Subscriber.*—In order to check mildew upon these, remove the worst of the leaves, dust the remainder with sulphur, and keep your frames warmer in night than you have been accustomed to do. Flowers of tobacco will also kill Thrips; let it remain on the leaves for a few days, and then give them a good washing with the syringe.‡

FRUIT-TREES.—*J. B.*—The following are good dessert Apples:—Early Harvest, Pearson's Plate, Golden Reinette, Golden Harvey, Court of Wick, Reinette du Canada, Court-pendu Plat, Nonpareil Russet, Stunner Pippin. For Kitchen use:—Dumelow's Seedling, Alfriston, Bedfordshire Foundling, Dutch Codlin. *Pears*—Marie-Louise, Beurré Rose, Bosen's Incomparable, Glout Morceau, Passe Colmar, Thompson's Winter, Beurré Rance; and, for Baking, Red Catillac. *Plums*—Royal Hâtive, Reine Claude Violette, Kirke's Washington, Coe's Golden Drop ‖

FUCHSIAS.—*W. G.*—Exoniensis, Formosa elegans, Roberti, Venus victrix, Colossus, Splendens, Conspicua arborea, Kentish Bride, Pontay's Tricolor, Insignis, Radiata, and Miller's Constellation *

GOOSEBERRIES.—*D.*—The following varieties are distinguished for rich flavour rather than large size:—Red Champagne, Red Turkey, Keen's Seedling Warrington, Early White, Woodward's Whitesmith, Hebburn Green Prolific, White Pig, Pitmaston Green Gage, Yellow Champagne, Taylor's Bright Venus, Red Warrington, Rumbullion. Nurserymen in the county in which you reside will most likely be able to furnish all, or most of the above. ‖

GRAPES.—*D. R.*—The London Nurserymen having informed you that they have sent out all their disposable stock of the Black Muscat of Alexandria and Charlesworth Tokay, we cannot inform you where these rather scarce sorts of Grapes are to be procured ‖

GUANO.—*R. W. B*—We should prefer applying guano in a liquid state to Carnations, rather than mixing it with the compost, or as a top dressing; 4lbs of guano to 12 gallons of water will be found a good proportion; it should remain for 24 hours before being used; the same guano will do for mixing again with the same quantity of water after the first is drawn off.—*M. H. H.*

HEATING.—*Walberton.*—If you want air-heat, slate tanks are best. If bottom heat is your object, we cannot at present advise you to use slate, except for the tops.——*P. Tomkins*—The best mode of securing the joints of hot-water pipes is by means of tar-rope untwisted and thick red-lead. Probably your joints are badly packed ——*R. D.*—The smallest boiler you can get Wait a little, and perhaps you may find the plan of one to your mind in our columns.

JONQUILS.—*A Subscriber*—The reason why your Jonquils do not flower freely arises from their leaves being cut off in summer while they are in a green state. The bulbs should be taken up when the foliage has become yellow and dried. If they are allowed to remain in the ground all the year they generally become exhausted, and do not flower freely. They require to be kept rather dry in winter. ¶

MAGNOLIAS.—*M grand flora* and its varieties are the only evergreen Magnolias The two best others are M acuminata and macrophylla Your other question has been often answered in former columns

MANURES.—*Late*—As far as our experience goes, Potter's guano beats everything Three or four cwt an acre are sufficient. Whether such manures can be advantageously applied year after year, remains to be seen We apprehend it will eventually be found useful to mix them with stable litter, which they will render very powerful, because of the mechanical action of the litter.——*Herts.*—We cannot tell what No 2 is good for No. 1 is not guano, but *rubbish*

NAMES OF FRUITS.—*P Q*—Your Apples are 2, Top Apple; 29, Beauty of Kent; 29, (perhaps) White Costin; 37, Blenheim Pippin, 41, Kentish Fill basket, 43, Holland Pippin ‖——*T Barnes*—Your Apples are a variety of Codlin ‖——*P. W. M.*—The Apple you sent, of a green colour, with a thick russeted base, and which you state is called "Little Herbert" or "Herbord," is not known by any other name ‖

NAMES OF PLANTS.—*Indiana Meta*—Trapa bicornis is a tender aquatic, requiring the same management as a greenhouse Water Lily ——*A M.*—A Tradescantia, and perhaps T. crassifolia ——*A Beginner.*—Schinus Molle ——*J C L*—Oncidium pubes.——*J. H G*—Apparently some male Chenopodiaceous plant, but we are unacquainted with it; neither do we know such a Gladiolus as you mention ——*G. R.*—Bæobotrys arguta ——*M*—The Ipon tea is new. It will, however, we fear, travel badly, and therefore be hardly worth exhibition. ——*C M S.*—Apparently some Juniper probably the common one ——*L B.*—1, Erica Westcottii; 2, E. colorans; 3, Dioama capitata.

PANSIES.—*W G.*—Brown's Curion, Maid of the Mill, Cook's Mulberry superb, Sulphurea elegans, Pearson's Black Prince, Major's Bridegroom, Thompson's Eclipse, Miss Stainforth, Ultra flora, Corona, Jewess superb, King's Exquisite.*

PEAS.—*R S.*—The "British Queen," the same as Knight's Tall Marrow Pea, grows to the height of 6 or 8 feet. Some of it may be sown now, and more in the end of May, for a late crop.‡

PRESERVING BLOSSOMS.—*A Subscriber.*—Garden-mats are not fit for sheltering the blossoms of fruit trees. You should employ some material that allows the light to pass through, and hang it an angle of 30°. Very coarse canvas will do.

ROSES.—*T S*—Perpetual Roses, if for free standards, should be cut back much; if trained on walls or trellis, only down to the ripe wood.

WILLOWS.—*Caledon*—There is no objection to your soil, if it is not dry. You had better get cuttings of the best sorts from the neighbouring osier-grounds, for we doubt whether you can procure them easily by the Botanical names. Salix viminalis and triandra are considered the most useful for fine work.

MISCELLANEOUS.—*J C L.*—No one knows what the Spirit Eagle is.——*A Beginner.*—We really cannot answer such a string of questions. The reply would occupy half a column. Besides, you will find nearly all your inquiries answered on former occasions, and must search for yourself.——*Geelyn.*—The Cedar of Lebanon strikes as freely as the Deodar, if the cuttings are taken from a young and vigorous tree.‡ ——*Aliquis.*—A hotbed, by having the litter mixed with tan, will continue in heat longer; but the tan will render the litter useless as manure. Leaves are best for the purpose ‡——*Sensus.*—Common manures, as far as we know, make the best dressing for Cauliflowers. ‡——*R.* is answered in last week's paper, p. 166. ‡——*Guschenet* may cut down the flower-stems of Hyacinths, when the flowers have died off them; but the foliage should be left until it becomes yellow and withered. ‡——*T. B*—You should consult some of the classed Catalogues of Roses, and our former pages. It is impossible to fill space with such long lists as you ask for, and which have been given already.——*A. B.*—The cause is probably cold and damp, either of the atmosphere or roots.——*J. B.*—Train Clematis flammula to the posts of your pigeon-houses. ——*S. T*—The front of your pit is *a* on the section. There plant; our Melons, and train them on a trellis near the glass.‡ ——*G. P.*—Please to send your address to the office.——*J. R.*—Galangale is the underground root-stock of Alpinia Galanga, a plant allied to Ginger, and harmless.——*A Subscriber*—We do not know where the Trinidad Pine is to be seen; it is not at all like the Cayenne Ita.——*Guichenet's* letter is sent to Mr. C. H.——*J. M'I.* is requested to forward his address.——*A. B.*—Orangee may be whip grafted in the common way.‡ ——*T. M.* will find directions for the management of Orchidaceæ given at p. 119, 1843. ‡——*Virgil.*—The Cicrelean Willow is Salix alba.

SEEDLING FLORISTS' FLOWERS.

CINERARIAS.—*J. and T. G.*—The flower of your blue seedling is small, and the disk too large in proportion to petals; the colour, though good, is not uncommon. The rose-lilac variety, with broad well-formed petals, is a much better flower; the colour is pleasing, and if the flower expands well (which it has not done in water), it will prove a desirable flower.——*W. P. W. R.*—Your seedling is a half-coloured, well-formed variety; the petals are a little too pointed, but the flower opens well, and is large and showy ¶

¶ All communications have been received too late for answering this week.

PASTURE AND LAWN GRASSES of the finest quality, selected for every description of soil, comprising all Rye, Perennial, Cocksfoot, Meadow Foxtail, &c., with a large supply of Clover, will enable Noblemen and Gentlemen to lay down upon very reasonable terms. Particulars of quantities suitable to various soils to be had, with an estimate of the cost per acre, by application to WARNER and WARNER, Seed-merchants, 26, Cornhill, London. Genuine Italian Rye-Grass, Mammoth Wurtzel, and superior selected Turnip Seeds.

TO BE SOLD, a Handsome Short-Horned Bull, named "Marengo," roan, calved Sept. 4, 1840, (bred by Mr. Whittaker, by the Prince of Northumberland, dam by Norfolk (13,772), Medora by Ambo (1656), g. g. d. Blossom by Memnon (2196), g. g. g. d. own sister to Isabella by Pilot (496), g. g. g. g. d. by Agamemnon, g. g. g. g. g. g. d. by Harrell's bull. He obtained the first prize at Glastonbury Cattle Show, in 1843. To be seen at Calcott, near Bridgewater, by application to Mr. Thomas Jones, at that place, or Mr. Joseph Latch, Newport, Monmouthshire.

March 26 { Radleigh. Wrentham. Debenham. Stoke Ferry. Grove Ferry.
March 28 Richmondshire.
March 30 { Gloucester. Cardiff.

THE CULTIVATION OF THE PARSNIP resembles that of the Carrot in every essential point. The land should be prepared as stated last week for the Carrot. Especial care should be taken in this, as in that case, to have a deeply-cultivated soil. In the Channel Islands, where this root is largely grown, it is customary in the preparation of the land to use the large trench plough,* and bury the manure—20 tons per acre of stable manure—12 or 14 inches deep. This is of course only practicable on deep soils, and it is on such, whether light or heavy, that this root flourishes. Parsnip seed may be damped, mixed with sand, just as in the case of the Carrot, and drilled early in April at the rate of 4lbs. per acre, in rows on the flat, 18 inches apart. New seed only should be used. Colonel le Couteur informs us, in the Journal of the English Agricultural Society, that seed sown in 1838 would not vegetate in 1840, though soaked and sown in a greenhouse. The damping of the seed, though we have advantageously adopted this plan in the case of the Carrot, for the last three years, is to a certain extent hazardous. Seed thus sprouted, if sown on a dry soil, is liable to be deprived of life. After having been thus treated it must not be sown till the land is damp. The summer culture of the Parsnip is just the same as that of the Carrot. An average weight of from 9 to 11 tons per acre is obtained of it in Jersey. We have not had much experience in the field culture of this root, but we are inclined to think that however superior it is to the Carrot in quality, *i. e.* per cwt., the superiority in the weight of the latter crop renders the Parsnip inferior to it per acre. It is most excellent food for Cows, imparting a rich flavour to the milk, and it possesses extraordinary feeding properties when given either to oxen or Pigs. It should be steamed for the latter; and when thus treated it is a nourishing food for poultry also.

EVERY farmer is aware, that where old pasture land has been broken up, and is again laid down to Grass, many years elapse before it recovers its original productiveness. This arises from the destruction of a LAYER OF MOULD immediately below the turf, which, whatever the colour and composition of the subsoil, is invariably black, composed of very fine particles, and destitute of pebbles, however numerous they may be near the surface in the adjoining arable land. What is the origin of this layer of fine earth? It is generally called vegetable mould, and is supposed to have resulted from the decay of the roots of the Grass. In a paper communicated to the Geological Society in 1838, Mr. Darwin has adduced strong arguments for its being of animal origin, and composed of the accumulated excrements of the earth-worm, usually denominated worm-cast. It is a prevalent opinion among farmers that mineral manures, such as lime, chalk, and burnt clay, have a tendency to sink in the soil. If Mr. Darwin's views are correct, it would appear that, instead of these substances sinking, the mould is mixed over them by the agency of the worms.

His attention, he says, was first drawn to the fact by Mr. Wedgwood, of Maer-hall, Staffordshire, who showed him several fields, some of which, a few years before, had been covered with lime, others with burnt marl, and cinders. These substances, in every case, are now buried to the depth of some inches beneath the turf. These fields were examined with care. The first consisted of good [illegible] land, which had been limed without having been ploughed, about twelve years and a half before. The marl was about half an inch thick, and two inches and a half beneath it was a layer or row of small aggregated lumps of the lime, forming at an equal depth a well-marked white line. The soil beneath this was of a gravelly nature, and differed very considerably from the mould nearer the surface. About three years since, cinders were likewise spread on this field; these are now buried at the depth of one inch, forming a line of black spots parallel to and above the white layer of lime. Some other cinders which had been scattered on another part of the field, were either still lying on the surface, or entangled in the roots of the Grass. The second field examined was remarkable only for the cinders being now buried in a layer nearly an inch thick, three inches beneath the surface. This layer was in parts so continuous, that the superficial mould was only attached to the subsoil of red clay by the long roots of the Grass. The history of the third field is more complete. Previously to 15 years since, it was waste land; but at that time it was drained, harrowed, ploughed, and well covered with burnt marl and cinders. It has not since been disturbed, and now supports a tolerably good pasture. The section here was—turf, half an inch; mould, two inches and a half; a layer, one and a half inch thick, composed of fragments of burnt marl (conspicuous from their bright red colour, and sometimes of considerable size, viz., one inch by half an inch broad, and a quarter thick), of cinders, and a few quartz pebbles mingled with earth; lastly, about four inches and a half beneath the surface was the original black peaty soil. Thus, beneath a layer (nearly four inches thick) of fine particles of earth, mixed with some vegetable matter, those substances now occurred which, 15 years before, had been spread on the surface. Mr. Darwin states that the appearance, in all cases, was as if the fragments had, as the farmers believe, worked themselves down. It does not, however, appear at all possible, that either the powdered lime, or the fragments of burnt marl and the pebbles could sink through compact earth to some inches beneath the surface, and still remain in a continuous layer. Nor is it probable that the decay of the Grass, although adding to the surface some of the constituent parts of the mould, should separate, in so short a time, the fine from the coarse earth, and accumulate the former on those objects which so lately were strewed on the surface. Mr. Darwin also remarked that, near towns, in fields which did not appear to have been ploughed, he had often been surprised by finding pieces of pottery and bones some inches below the turf. On the mountains of Chili, he had been perplexed by noticing elevated marine shells covered with earth in situations where rain could not have washed it on them.

Mr. Darwin likewise records the following circumstance, communicated to him from Staffordshire, respecting two fields:—1st. In the spring of 1835, a boggy field was so thickly covered with sand, that the surface appeared of a red colour; but the sand is now overlaid by about three quarters of an inch of soil. 2d. About 80 years ago a field was manured with marl, and it has since been ploughed, but it is not known at what exact period. An imperfect layer of the marl now exists at a depth, very carefully measured from the surface, of 12 inches in some places, and 14 in others, the difference corresponding to the tops and hollows of the ridges and butts. It is certain that the marl was buried before the field was ploughed, because the fragments are not scattered through the soil, but constitute a layer, which is horizontal, and therefore not parallel to the undulations of the ploughed surface. No plough, moreover, could reach the marl in its present position, as the furrows in this neighbourhood are never more than eight inches in depth. The preceding cases have shown that three inches and a half of mould had been accumulated in 15 years; and in this case within 80 years (that is on the supposition, rendered probable from the Agricultural state of this part of the country, that the field had never before been marled) a bed of earth had accumulated averaging 13 inches in thickness.

The explanation of these circumstances which first occurred to Mr. Wedgwood, although it may at first sight appear trivial, Mr. Darwin does not doubt is the correct one; namely, that the whole is due to the digestive process by which the common earth-worm is supported. On carefully examining between the blades of grass, in the fields above described, the author found that there was scarcely a space of two inches square without a little heap of the cylindrical castings of worms. It is well known that worms swallow earthy matter, and that having separated the serviceable portion, they eject at the mouths of their burrows, the remainder in little intestine-shaped heaps. The worm is unable to swallow coarse particles, and as it would naturally avoid pure lime, the fine earth lying beneath either the cinders and burnt marl would, by a slow process, be removed and thrown up to the surface. This supposition is not imaginary; for in the field in which cinders had been spread, only half a year before, Mr. Darwin actually saw the castings of the worms heaped on the smaller fragments. Nor is the agency so trivial as, at first, it might be thought; the great number of earth-worms (as every one must be aware who has ever dug in a Grass field) making up for the insignificant quantity of work which each performs.

On the above hypothesis the great advantage of old pasture land, which farmers are always particularly averse from breaking up, is explained; for the worms must require a considerable length of time to prepare a thick stratum of mould by thoroughly mingling the original constituent parts of the soil, as well as the manures added by man, and of the peaty field about three inches and a half had been well digested in 15 years. It is probable, however, that the process is continued, though at a slow rate, to a much greater depth; for as often as a worm is compelled, by dry weather or any other cause, to descend deep, it must bring to the surface, when it empties the contents of its body, a few particles of earth.

Mr. Darwin was prepared for the formation of a bed of earth by the digestive process of small animals, from what he witnessed in the coral islands of the Pacific. He there saw through the deep clear water multitudes of fishes of the genus Sparus browsing on living corals, like herds of grazing quadrupeds, and, on opening their bodies, he found their intestines filled with a substance resembling impure chalk. From this he was led to the opinion that much of the soft white mud found at the bottom of the sea near coral reefs had passed through the intestines of fishes, and other portions through those of worms, by which the stony masses of the coral are everywhere bored.

The above statements and opinions of Mr. Darwin on the formation of the mould of pastures are laid before our readers in the hope that it may lead them to make observations on the subject and to bring forward other cases similar to those which have been described. If it shall be established by more extended observations this will be only one out of the many instances in which the operations of Nature present to our view important results, produced by the most insignificant agents, which make up by their numbers and incessant activity for their individual weakness. The poor despised "worm of the earth," the very emblem of weakness and vileness, is, perhaps, one of the farmer's best friends, for it appears highly probable, that every particle of the surface soil has passed through the intestines of worms. The Agriculturist, as Mr. Darwin has observed, in ploughing his land, follows a method truly natural, and he only imitates in a rude manner, without being able to bury the pebbles or to sift the fine from the coarse soil, a work which Nature is daily performing by the agency of the earth-worm.—*E. W.*

ON FEEDING FARM-HORSES.

IN this part of the country, the following plan of keeping farm-horses is generally adopted:—As soon as there is a sufficient bite (which is not usually the case till the middle or end of May), the horses are turned out to grass at nights, and receive their usual allowance of corn,—3 feeds of a gallon each, and perhaps a little Hay during the day. This management continues till the Clover is ready for cutting, a bunch of which is substituted for the mid-day feed of Corn. When the Turnips are all sown, and the hard work consequently over, most farmers reduce the allowance of Oats, and give Clover instead; and in the early part of harvest, when horses are generally quite idle, they often get no Corn. When the leading-in of the crop commences, they are again put upon Corn; and as the Clover is then generally all consumed, they receive Tares instead, as their mid-day meal, and when these are finished, Corn or Hay. During all this time, the horses have been constantly turned out at nights; but about the middle of October, or whenever the weather becomes chilly or unsettled, they are kept in the house, and they now receive full feeding, *i. e.*, 3 feeds of Corn per diem, and Hay *ad libitum*. This management is continued throughout the winter; but most farmers, during the short days, give Oat or Wheat-straw instead of Hay for two or three months, generally those of November, December, and January.

Throughout the winter, too, most farmers give boiled or steamed Barley at nights, twice or thrice a week; of this, each horse gets about 2 gallons. To such horses as will eat them, one or two Swedish Turnips are also given once a day, which tends greatly to keep them in condition.

When Whitsunday again comes round, the horses are put out to Grass, as I began by describing. Although there are many little differences in practice, yet the above is the general management of farm-horses in this county, and, indeed, throughout all the southern counties of Scotland.—*A. J. Roxburghshire.*

P.S. I should mention that the working hours are, in spring, summer, and autumn, from 6 o'clock till 11, and from 1 till 5. In the winter months they are from daylight till dark, with an interval generally of an hour, or an hour and a half as the days lengthen.

ON MINERAL AND INORGANIC MANURES.

No. X.

By PROFESSOR CHARLES SPRENGEL.

There are also cases where marl may improve vegetation by containing protoxide of manganese. It is the humic

* See paper on this subject by Colonel le Couteur, in the 3d Vol. of the "English Agricultural Society's Journal."

acid, by which it is carried into the plants, and here again the importance of the latter substance is seen.

The clay of marl is especially useful to such soils as are subject to drought, because a soil may contain all the substances required for the nourishment of plants in sufficient quantity, and still be unprodnctive, if it is deficient in water, which has to convey the nutritive substances into them; and clay retains water for plants in dry weather. Besides that, the alumina of the clay, which has a great affinity for humic acid, will also somewhat decompose the coal of humus and the vegetable matter of the soil. It is also to be remembered, that alumina, the protoxide of manganese, lime and magnesia, potash, soda, and the oxide of iron of the marl will equally prevent the decomposition and useless volatilisation of the humic acid, as these substances fix it chemically.

Marl also improves vegetation by the silica which it contains, i. e., in those soils which are deficient in this substance, for instance moor, peat, or marshy soils. The sorts of marl which are very rich in lime, and at the same time sandy, improve clayey soils by loosening them.

If marl contains (which is sometimes the case) sulphuret of iron, it will be converted, by contact with air, into sulphate of the oxide of iron, which again becomes decomposed by the carbonate of lime, so that gypsum will be formed, which will naturally increase the manuring quality of the marl, as we shall see hereafter.

Marl, however, contains at times a substance detrimental to vegetation, viz., carbonate of the protoxide of iron. I have found this to be the case in two instances. Such marl is generally found under marshy soils, and contains remains of fresh-water shells. In using this sort of marl we must guard against ploughing it under too soon; it must be spread and left lying on the ground till the protoxide of iron has been changed into oxide of iron, which will be seen by its grey colour having changed into yellow, which, however, will take up sometimes a whole summer. If a marl containing much carbonate of the protoxide of iron is ploughed under too soon, the humic acid of the soil will combine with the protoxide of iron into a salt, which is very noxious to plants. Carbonate of iron will, like carbonate of lime, effervesce if acids are poured upon it, and this may lead us into error when calculating the amount of lime which a marl may contain. From the different statements I have made about the action of marl, it will have been seen that it is not merely the carbonate of lime or the clay which constitutes its worth as a manure; still, generally speaking, those sorts are considered best which contain most of the former substance. It is, therefore, mostly tested only as to the amount of carbonate of lime it contains, but it would be as well to take notice of all its other component parts.

The question, how long will marl act? has been often raised. If, however, we consider that it supplies the plants with different nutritive substances, which occur in it in very different proportions—that these substances are taken hold of by plants in very different degrees—that many of these ingredients are carried away by rain or snow-water; if we consider, in short, that plants are also deprived of part of the lime and magnesia by these latter substances combining with the silica into substances insoluble in water, it will be seen that this question can never be accurately answered, even were the amount of marl spread on a certain area accurately known. The repetition of the marling is always dependent on the quantity used at any former occasion—on its chemical constituents—on the component parts of the soil—on the sort of crop reared—on the nature of the subsoil—and on the annual amount of rain. If, for instance, any sort of marl owes its manuring properties to the gypsum and phosphate of lime which it contains, its application will have to be often repeated, as it rarely contains much of these substances, and the gypsum becomes easily extracted by the water. The same is the case if it improves vegetation by the magnesia which it contains, as of this also most marls contain but very little. If, on the other hand, the value of marl depends on its carbonate of lime (which will be the case whenever the soil possesses the other nutritive substances to a sufficient amount,) it will require to be repeated only after a lapse of twenty or thirty years, it being understood that the first supply has been to a considerable amount. Because, though a small quantity of lime be dissolved and carried off by the rain-water, which contains carbonic acid, or though another portion of it combines with the silica of the soil, still enough will remain for the use of the plant, supposing that only 10,000 lbs. of a calcareous marl have been conveyed on one acre of land. Whoever wishes to ascertain before hand, with some degree of accuracy, how long a certain quantity of marl will act, has to subject to chemical analysis the marl itself, as well as the soil to be manured by it; and having accurately ascertained the component parts of both, he may form an estimate, by deducting the amount consumed by every crop, and that which is annually carried off by the rain. Though, however, all the nutritive substances of marl have been consumed by plants, it will act beneficially on dry soils for centuries, if it contains much clay; both because this will supply the plants with moisture, and because the drier the soil the smaller the quantity of soluble matter that can be absorbed by the crops.

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. X.

(Continued from page 139.)

As I divided the chemical composition of plants into organic and inorganic, the same division must be adopted in treating of their food; but it will be more convenient to discuss the subject under the general head of

Manures, or the Food of Plants.—If any person has any difficulty in comprehending how manure applied to the soil, serves as nourishment to the plant, let him revert to the fact which he may daily witness in that beautiful process which is undergone in the incubation of the egg.

If a chemist analyses the white and yolk of the egg, he finds them identical in chemical composition, with the source of all animal nutriment—the blood; and he thus has no difficulty in solving the problem, how they are converted or organised into the perfect bird. So, if he examines the plant upon which animals feed, he finds there also the essential elements of blood from which all organised animal structure is formed. And again, if he examines the proper food, or manure of the plant, he finds in that the elements necessary for the structure of the vegetable. All difficulty at once vanishes from the subject, except a knowledge of how the mysterious principle of life performs its agency. Of this we know nothing, and it is not probable that a finite mind will ever be able to comprehend it.

Chemists, then, have no difficulty in deciding, that plants, to be grown in perfection, must have a supply of food which is similar in composition to their own ultimate structure. But Nature is sometimes obstinate in refusing the interference of man; she is always so when, from ignorance of her laws, that interference is misapplied. Granting that plants must be fed, it must always be remembered that, like animals, they require due attention to be paid to the quantity and quality of their food. For instance, although quite true that to form Gluten and Starch in the seed of grain, the plant must have supplied to it the elements of these substances, it by no means follows, that if Gluten and Starch in their pure state were given to the plant, that it would appropriate the food so offered. We must in these inquiries study and follow out the plans of Nature herself.

In primeval forests, where the trees grow to an enormous height, live, and flourish, and die, without the interference of man, how does Nature provide their food? The question is not difficult to solve. Of organic matter they require the elements carbon, hydrogen, and oxygen, to form the fabric of the plant; and in many cases, a fourth element, nitrogen, either for the perfection of their seed, or to be stored up for ulterior purposes.

The carbon is supplied from the atmosphere. The carbonic acid in the atmosphere is about one part in a thousand; and yet Liebig has calculated that this apparently small amount would produce more solid charcoal than all the vegetable kingdom and all the brown coal on the surface of the earth. By the decomposition of water the other elements, oxygen and hydrogen, are provided. Then, of nitrogen we have a source in the atmosphere, which Liebig has proved to contain a constant quantity of ammonia. But the atmosphere only nourishes plants in part. The Oak, with its immense branches, has roots as large in the interior of the earth constantly at work in selecting and appropriating proper food to the purposes of nutrition.

This food in the earth is supplied by the decomposition of the leaves and branches, forming humus; by the decay of animal matter, forming ammonia; and from rain, charged with this substance, which is constantly falling upon the surface of the earth. Of inorganic matter the supply is derived from the disintegration of the subjacent rocks.

In the wilds of Nature, with the food of Nature, we see these works of the Creator in their boldest magnificence and beauty, and there every living thing finds the means of subsistence; but civilisation, want of luxuries, and, above all, the gradual increase of mankind, create the necessity of bringing into action the aid of science in developing the resources of Infinite Wisdom.

In the food of plants which Nature restores to the soil we observe that the process of decomposition takes place before it can be appropriated by the vegetable organism to the purposes of nutrition. Vegetable matter decomposing is converted into humus. Humus is converted, by decomposition of its constituents, into carbonic acid—it is burnt, in fact, by the action of oxygen. Carbonic acid, again, is resolved, by chemical agency, into carbon and oxygen. And thus the ultimate elements of the old plants are reconverted into what are termed the proximate elements of the new, and woody fibre, starch, gum, &c., are the result. This cycle of changes is in never-ceasing activity throughout the scale of living beings. It does not, however, apply to inorganic matter, which serves no purpose in the nutrition of the plant, properly so called. Their use in the vegetable economy is either to give strength and durability to portions of the fabric, or to be stored up in its cellular structure, with the evident and beautiful design of being appropriated by the animals which feed on it.

Decomposition, then, is the first great principle to be attended to in the preparation of organic manures.

The second is to secure to the plant the results of decomposition, by fixing the volatile salts, which would otherwise be lost.

And having prepared the manure, a third object will present itself—that of applying it, with a due regard to the chemical composition of the crop to be grown, and to the necessities of the soil in which it is to be planted.—*C. R. Bree, Stowmarket.*

(To be continued.)

Home Correspondence.

Lucerne.—An article appeared in a recent Number of the *Gardeners' Chronicle* calculated to mislead many farmers who might be induced to adopt the method recommended by Mr. John Sandford and Mr. A. Hall for the cultivation of Lucerne. All husbandmen, particularly those who would know "the true principles of tillage" and grow Lucerne in the proper way, should read Jethro Tull "On Drill Husbandry." This valuable book was written more than a century ago, but there was a reprint some few years since by the late William Cobbett. It will require no great penetration to discover, by perusing this work, that the principles of Mr. J. Sandford, and Mr. A. Hall, of the Chepstow Farmers' Club, are not "the true principles of tillage." Lucerne roots deeply, so deeply that a dry surface will not materially affect its growth. If properly cultivated the crown of a plant will spread as widely as the palm of the hand, and Grasses of any kind (its greatest enemies) will, if permitted to grow, always injure it, and ultimately destroy it.—*Nicodemus.*

Scotch Agriculture.—The following extract, taken from the account of the parish of Dunbar, published in the "Statistical Account of Scotland," may be interesting to some of your readers, as bearing on the questions regarding the food of plants. It is from the pen of the clergyman of the parish, who is an able man and zealous Agriculturist. "The soil being dry, is easily pulverised and cleared of root-weeds, therefore there is comparatively but little fallow. The rotation of crops is:—1. Turnips, upon two or more ploughings, dunged, and generally fed off; when carried off, a compost of lime and earth is generally applied. 2. Wheat, with Clover and Rye-grass seeds. 3. Grass, fed off with cattle or sheep. 4. Potato Oats. 5. Beans, drilled and dunged. 6. Wheat. Instead of Oats, Wheat is sometimes taken, and then the rotation is confined to four crops. This course, peculiar to the parish, has been called the Dunbar system; but objections have been made to it. Wheat every second year, it is said, exhausts the soil; the answer is, that the food of plants in the soil may be exhausted by any crop, while the soil itself cannot be exhausted. Where there is a command of manure, there is no system which will so richly repay the labours of the husbandman. It was adopted here for many years on one of the best farms, without any diminution of either quantity or quality. And in order to ascertain whether soil is injured by frequent crops of Wheat, the glebe of Dunbar (the clergyman's allotment of land), was properly dressed, either with sea-weed, street dung, or soot, and cropped with Wheat for five successive years. The result was, an extra crop every year, and the land left in a condition that it may produce a crop or two of any kind without additional manure. The least crop in the succession was on the third year—10½ bolls (5¼ quarters) per acre; it promised to be the greatest, but it was lodged flat as the surface soon after it came into ear. All the other crops were above 12 bolls (6 quarters) per acre. One season, exactly suited to the soil, there were 16½ bolls per acre; and the last of the five years there were 14 bolls per acre. It was ascertained that on each of three of these years there were more than 300 stones of straw per acre. The soil is a sandy loam. There is another field in the parish which has produced Oats four successive years with increasing produce and fertility. Hence it seems to follow that land, properly cultivated and manured, may produce abundantly the same kind of crop in regular succession. If the food of plants is exhausted in exact proportion to the weight of crop produced, it is worthy of investigation whether the advantage of changing the kind of crop arises, not from one kind giving off food for another kind, but solely from the different modes of cultivation which different kinds of crop admit of at different seasons." Thus far the Minister of Dunbar. I will only add, that the parish is in East Lothian, and stretching along the sea-coast, enjoys one of the warmest and driest climates in Scotland.—*J. S.*

Dairy Management.—Our Somersetshire dairymen are complaining bitterly of the great depression in the value of their dairy produce. It would be happy for them, if their complaints would lead them to see clearly the necessity of a change of system in their dairy management, which is generally as bad as it can be. The cows are out all the winter, and the pasture land is very much exposed to land floods, as it lies very low, especially in the neighbourhoods of Wales and Glastonbury; the consequence of which is, that the Grass resembles a ploughed field, from the constant tread of the animals, and the deep impressions which their feet make in the soil filled with water. Rarely do you see any sheds for shelter. The Grass, of course, cannot provide sufficient food for them, and Hay is brought to them and thrown down in different lots, which again injures the pasture land, as it is completely trodden down, and worked up by the treadings of the animals, and in rainy weather the nourishing juices of the Hay are soon washed out, and very great waste is the consequence of this mode of feeding. It is evident also that the manure is completely wasted. Under such a system, it cannot be reasonably expected that the produce of milk can be very great. The constant exposure to cold and wet must be injurious also. The greatest want of economy appears in the whole of this system.—*A Dunmowshire man.*

Steeping of Seeds.—Animated by the statements in the January Number of the "Agricultural Journal," I commenced a series of trials of soaking seeds in solutions of the sulphate of soda, ammonia, magnesia, and nitrate of potash, guano liquified, &c., both singly, and in various combinations. The seeds subjected to the process were those of Wheat, Beans, Oats, and Turnips, and Linseed. In every instance the vitality of the seed has been destroyed. I have entered upon a new set of experiments with solutions of much greater dilution; such as 5 oz. of the salt to a pint of water; but I feel this is some great work, and wish to inquire whether you have made any attempt to ascertain within what limits these saline solutions may be safely employed. I fear the quantity recommended in your Paper No. 6, viz., 5 lbs. of the salt dissolved in one

merely sufficient to cover the seed, may prove too strong. May I be permitted to suggest that these seeds after steeping might be dried in some of the powders suggested by "Victor" in the "Journal of Agriculture," page 216? I have just come from an attempt to dissolve 320 lbs. of bone-dust in 160 lbs. of sulphuric acid in the manner recommended by Mr. Lawes, in the last *Agricultural Gazette*; the heat produced and vapour was so great, that if the windows and doors of the mill where the process was tried had not been thrown open, my fellow experimenter and self would have been suffocated. I mention this as a caution to any parties who adopt the plan suggested by Mr. Lawes. I think it should only be attempted in the open air.—*A. Hurstable, Sutton Rectory.* [The drying powders alluded to are powdered clay, bone-dust, charred animal matter, &c. We have put 5 lbs. of each of the salts we named into about 1½ bucketful of water, and placed the Wheat in it, about ¾ of a bushel. It is all in the ground, and we can only hope that it will not share the fate of our correspondent's unlucky seeds. These experiments are necessarily guess-work, and experience alone can teach the right proportions of the materials to be used.]

A communication from "Rustic Robin" describes the advantages of ploughing in a mixture of lime and earth applied to Clover ley. The superiority of the Wheat crop after this manuring could be distinguished many fields off.

Cow-Wheat.—In the *Chronicle* for last year, a Correspondent from the Isle of Wight mentioned that the weed called Cow-Wheat had appeared in that island amongst the corn, and he conjectured that it might have been introduced with some seed Wheat from Norfolk. I believe that the plant in question is the *Melampyrum arvénse*, which is indigenous to this county. Mr. Crow, the botanist, says it grows "between Norwich and Cossey, and Bixley, near Norwich." I have made some inquiries amongst farmers respecting this weed, and they do not seem to know it; hence we may conclude it is not very troublesome.—*J. Wighton.*

Draining Materials.—"A Surrey Farmer" is entitled to credit for bringing under notice the efficacy of Scotch Fir poles as a draining material, but his plan of using them is not to be recommended. I shall endeavour to point out a cheaper, better, and more lasting one. In the first place, sawing the poles lengthways is not only a useless expense, but they will not last half so long as when placed in the drains in a round state with the bark on; but I agree with him that the poles should be cut when the sap is up. A few years ago I effectually drained a piece of bog-land, not previously worth 2*s.* 6*d.* per acre, and on which peat had been for many years cut for fuel. The plan I adopted was this: it was a flat piece of ground, and the land adjoining sloped gradually to it; I cut a drain seven feet deep between the dry land and the bog, and two feet and a half wide at the bottom, the substratum being gravel without any admixture of earth; by this means I cut off all the springs that fed the bog, and then I placed at the bottom of the drain strong Fir poles (the weedings of plantations), laying them horizontally end to end on each side of the drain, leaving a space between them of about ten inches, which, when completed, formed a funnel; and to secure the poles in their proper position I had cross bars to keep them apart nailed into them with spike nails, thus forming a sort of ladder which lay flat in the bottom of the drain. I then placed other bars between them, within a foot of each other, crossways without nails, and afterwards the branches lengthways with their fibres on. The surface sods, which were carefully preserved, were then placed so as to cover the whole with the Grass side downwards; and lastly, the drain was filled up with the excavated soil. The poles at the bottom had better be of unequal lengths, by which means the nailed bars will keep the whole line more firmly united. Where the drain crossed the sloping land as before described, I had some clay rammed in at the back of the poles at the lowest side, to prevent any of the water from percolating out of the funnel. Thus I succeeded in draining more land effectually, and at one-fifth of the expense, than I could have done with frequent drains, even if there had been a stone quarry in the field. With regard to durability, I have no doubt that Scotch Firs thus placed are superior to, and cheaper than, any other materials. Scotch Firs must answer equally well if used in a similar manner in frequent drains; but the drains must be cut to the depth of four or five feet, and they must also be at least twenty inches wide at bottom. The following year after I drained this piece of bog, it produced thirty strikes (of 40 grs.) per acre of Muncorn (Meslin). It was pared and burned, and an allowance of lime made to it at the rate of three tons an acre; the first crop nearly remunerating all expenses, and the land is now worth 30*s.* per acre.—*T. Jones, Newtown.*

On Storing Turnips.—The most approved and now generally adopted method of storing Turnips in Roxboughshire, is as follows:—The Turnips, deprived of their leaves and roots, are laid in an oblong heap, sloping up on both sides to a point, like a Potato-pit, and the outside ones packed close together, and a smooth uniform surface formed. The heap is then covered with dry straw to the depth of about 18 inches, which is secured and bound down by straw ropes. Turnips stored in this way generally keep well, and are scarcely ever touched by frost. Should it be late in spring before they are used, they are generally somewhat sprouted, but much less so than if they had been pitted in earth. Of course the length of the heap will depend on the quantity of Turnips. The breadth is generally about 10 or 12 feet. Swedes are generally stored in November or December.—*Ibid.*

Moles.—Wherever I go I see the trees and hedges covered with the dead bodies of the poor Moles, which

without mercy or judgment. I have wet meadows, in which they do me vast service. One of the meadows was so wet that no Mole worked into it, but only burrowed on the surface, barely deep enough to cover his body with the roots of the grass and weeds, and this only in the very dry, hot days of August—the only time when worms could be found. I dug a few drains, and the next summer found the Moles work as deep as the bottom of the drains, and into them. Another year these drains were cut as deep as the fall would allow, and the same result followed. My friends, the Moles, opened scores of their channels into the very bottom of these open drains, and the meadow is firm and sound. In all my meadows, finding the good they thus do, I never have them disturbed; but only in April send out a man to level their hillocks, then roll them; and I never have any complaint from the mowers. Depend upon it, they are very beneficial to all lands, particularly to wet bog-soil. Where 4-feet drains are made with inch-tile, they cannot enter, but would work at that depth in all directions, and be of the greatest possible use. The best open drains for meadows, if I may call them so, are some I have met with—thus made: The drains are cut about 6 inches wide, and as deep as the fall will allow—3 or 4 feet deep. In these finely-broken stones were placed to within one inch and a half of the surface; over them nothing is to be laid, the grass from the sides will run over the stones and meet, but having no earth, they act most completely as surface-drains, and as well as deep ones. They are most permanent, never out of order, never want anything done to them again.—*P.*

Pig-Feeding.—In my remarks on Pig-feeding, my observations were directed chiefly to fattening hogs to a large size; the strong food recommended does not exactly suit quarter porkers; it is too heating, and produces pimples, which give the appearance of disease; therefore, for quarter pork, I either use fine middlings with milk or pure water, or reduce the strength of the Barley and Pea-meal by adding an equal quantity of Pollard; wash or pot liquor is unpalatable to pigs during the process of fattening on meal. I have tried various liquids—mutton broth, the liquor from a round of beef, and good kitchen wash; but have always been obliged to take it out of their troughs, and replace it with meal and milk or water. It will sometimes happen, from change of weather or other causes, that the pigs get costive and are off their food; in such a case I supply them with a little green food according to the season of the year, as a few Cabbage leaves, Lettuces, or Potato tops, or with Potatoes, and Mangold Wurtzel: if, on the other hand, they are purged, I have a sod dug from the road side and given them, or, which I sometimes think is better, I let them into a yard where there are cinders, mould, and brick and chalk rubbish. I think very little of garden stuff as a means of keeping a pig in a good growing condition; it is no help farther than satisfying occasionally the cravings of hunger; sows will do on it, or on grass, if there can be added daily a feed or two from the wash-tub. As I keep sows I may as well add my management of them. During the time of gestation their diet is restricted to articles that will not produce obesity, for sows as well as cows are apt to be attacked with what is called the milk-fever; and besides, unwieldy sows have not that command over their movements that sows with a less proportion of flesh have, and are very likely to crush many of their young ones. For the first fortnight the sow is fed in such a manner as to leave off with a good appetite, and no better or more forcing food is given than fine pollard or coarse middlings; but as soon as all fever has disappeared, and the pigs can take the milk as fast as the sow can supply it, the finest middlings or oatmeal, or sometimes boiled rice, when it can be procured at about 8*s.* or 8*s.* 6*d.* per cwt., are given three times a day; the little pigs are cut when five or six weeks old, the sows are not spayed if intended for quarter pork; the operation both throws them back and disfigures them. Many people recommend a spayed sow for the poor; I always recommend a barrow pig, as growing to a larger size than the spayed sow pig, and in being far superior meat to an old spayed sow. These remarks, with what I forwarded you before, are about all I can remember for a brief sketch. In choosing a pig, look out one with a wide open chest, well filled up from the ears to the tail, small toed, and with meat in the fore arm down to the knee, and in the ham down to the hock; tail fine and short, with a small spread of hairs at the end. Let the breed be more inclined to make flesh than fat, and fine in the grain; another peculiarity should be ascertained—the breed should be famed for broad backs and small entrails; large-bellied pigs do not pull down the scale. You have now such a lecture on pigs as I sometimes give to my inquiring friends.—*J. Steele.*

Rooks.—It is singular how long men will argue about matters which facts only can decide, and when the facts might be so easily ascertained. Thus it appears by an article in the *Agricultural Gazette* of Feb. 17, p. 107, that it is yet a question whether Rooks do more good by destroying the larvæ of insects, or harm by eating grain. Now, surely this is a point which admits of being decided. What more easy than that a few sportsmen, when the game-shooting season is over, should each shoot his half-dozen rooks daily for a week, when they have made their morning's meal, and see by examining their crops what they actually contain; whether wireworms and other larvæ of insects, and slugs, &c.; and by taking the average of several days, calculate the good Rooks do in this way in the season when they have no access to grain. Again, let it be ascertained in the same mode, in seed-sowing time, both in autumn and spring, what is the relative amount of the grain and larvæ of insects, &c., which then serve them for food, and from these data the balance may be easily struck as to the good or harm done by them, and whether it is always in their favour, as some suppose, or is thought near Dumfries occasionally against them. It is to be hoped that another year will not have passed over without these important points having been ascertained, and made known through the *Agricultural Gazette.*—*S.*

Potatoes.—A correspondent asked some time back if seaweed had been used much in this neighbourhood for manure? It was not found to be of much value; but on a light loam with flinty gravel a foot below the surface, I find that the salt mud from a tide-river is an admirable manure for Potatoes. It is ploughed in fresh from the river side, before the furrows are drawn for Potato planting, and has produced an excellent crop this season without other manure. The tubers are large, clear skinned, and of very good flavour. The hint is worth the attention of those who live near any harbour, or arm of the sea. Probably Thames mud would be equally useful on light soils.—*C. D., Lavant, near Chichester.*

Experiment on Winter Fallow and Subsoil Ploughing.—This experiment was tried upon four fields, in all about 40 acres, consisting of drilled Bean stubble, and Oat stubble. The method adopted was the following:—Immediately after harvest, the fields were ploughed across, in drills, by furrows from nine to ten inches deep, laid together, and the subsoil-plough passed once between the drills seven or eight inches deep, the horses in the subsoil plough being yoked one before the other, to avoid treading on the ground subsoiled. During the dry winter weather, the drills were reversed, and the subsoil-ploughing between the drills was repeated as far as the season would allow it to be overtaken. By this plan of working, the ground was kept much drier, and a much larger surface exposed to the action of the atmosphere than is attained by the common method of winter ploughing; and the beneficial effects were evident even during the winter, from the ridges appearing drier and white, long before ground ploughed in the common way. Besides, the constant souring by the winter rains, so detrimental to clay ground, was in a great measure avoided, and the spring work rendered comparatively light and easy. At seed time, the ridges were ploughed up and down in the usual way with a light furrow—the seed furrow, of course across the drills, which, however, were never harrowed down nor interfered with, the action of the plough carrying forward enough of earth to fill up the hollows in the drills, and no more was ploughed in a day than could be sown and harrowed. In this way the rest of the field was left in the drills, and therefore less likely to be injured by the heavy rains of last spring. Part of the ground was sown broadcast, and part drilled by a single-horse plough, with a drill barrow placed between the stilts of the plough, the single-horse plough crossing the drills as in the broadcast, without being harrowed down. By this method the ground was rendered so fine, from not being so deeply ploughed, that the Grass seeds required only to be bush-harrowed, and the spring labour was rendered very light indeed. Notwithstanding the heavy rains of last spring, the Barley sowing was made very easy by this method of winter fallowing, and the same advantages were obtained in the Turnip ground, which had been similarly treated. The crop of Barley produced on the ground prepared as above, was a third more in bulk than that after Turnip ground treated in the usual way—the one being 35 threaves, and the other 45 threaves, per acre. The drilled Barley and the broadcast were nearly the same—if anything the drilled being more productive. In the Turnip field the following mode was adopted:—The winter drills were once ploughed across, and after being harrowed and rolled, the ground was immediately drilled up for receiving the dung—the rest of the field remaining in the winter drills, and thereby not suffering from the severe rains of last spring. A specimen of the Turnip may be seen in Messrs. Drummond's Museum. It may be useful to mention, that by taking the mould board off a common plough, it can be used as a subsoil-plough.—*Polmaise, Stirling, Sept.* 1843.

Spade Husbandry.—Your late Agricultural correspondent, the Rev. W. L. Rham, does not appear to have considered the subject of Spade Husbandry in all its bearings. I therefore trouble you with a few general observations upon that subject, which occurred to me after reading his paper. Both policy and philanthropy teach us that a labourer, able and willing to work, ought to be enabled to support himself by his labour instead of being, as unfortunately too many now are, a useless burden upon the land. But, in framing laws and regulations for the protection of property, we are too apt to lose sight of the only right a man who is destitute of it can claim as his inheritance—one more potent than all others—the right to live. When it is proposed to inclose and cultivate commons and waste lands, we are told that the lord of the manor has his vested right, and that the copyholders have their vested rights, in the waste, which cannot therefore be disturbed; but, surely, some plan might be devised to make all this unproductive land beneficial to the community, without injustice to either lord or copyholder. Why may not an Act of Parliament be passed empowering the guardians, or the principal ratepayers, to inclose all waste lands in their respective parishes, granting to all who now have a right of common, and to the lord of the manor, a certain portion of the land as freehold, in compensation for whatever loss they may sustain by the inclosure, the remainder to be appropriated to the support of the general poor? The benefit derived by those who now possess common-right is so trifling, that a small quantity of freehold property would be a fair equivalent; the surplus would therefore be considerable, and if well cultivated on the Spade Husbandry system by the able-bodied poor who are now living upon the labour of others, the produce would contribute to the

maintenance of the aged and infirm, and thereby materially lighten the poor-rates, which in the parish where I reside amount to the enormous proportion of nearly one-fourth of the rental. The plan I propose has probably been suggested before; but, whether or not, it seems to me worthy of consideration. This, however, is not the only way in which I conceive the spade might be advantageously employed instead of the plough. Dry, shallow soils, upon which in droughty seasons the crops are materially diminished in productiveness through want of sufficient moisture at the roots to maintain a vigorous growth of plant, would be greatly improved by digging. The average depth of mould stirred by the plough in such soils will not exceed 4 inches, at a cost of about 12*s.* per acre; while the same space might be dug 9 inches deep for from 24*s.* to 30*s.*, according to the texture of the ground; and, in such a case, I calculate that one 9-inch digging would be fully as beneficial to the land as two 4-inch ploughings. Spade Husbandry, therefore, would not add to the expense of culture. It would, of course, be preposterous to suppose that all tillage could be worked by the spade; but I maintain that *there is scarcely* a farm upon which manual labour might not, *in some degree*, be substituted for horse-labour; and, *if by such substitution* the number of *husbandry horses throughout* the kingdom could be reduced only *one in twenty* or thirty, a very considerable portion of land *now occupied* in producing food for those horses might be appropriated to the sustenance of human beings. Mr. Rham's objection to employ men in doing the work of horses ought not to stand in our way. Digging in a field is no more derogatory to the "majesty of man" than digging in a garden, nor is it harder work than many things which a farm-labourer is called upon to do in the routine of business. Unmitigated poverty, on account of its too frequent offspring—crime, tends more to the debasement of a man's nature than any kind of work, however menial, by which he is able to earn an honest subsistence.—*Horticator.*

Burnt Clay.—Clay, however well burnt, is a bad material for road-making, being too *soft* to stand the wear and tear to which roads are exposed; but, laying aside its inferiority, it would be cheaper to bring stone a distance of ten miles than to burn clay for ballast, with coals at 10*s.* per ton, on the spot. To burn clay to good hard ballast, it requires from two and a-half to three cwt. of coals per cubic yard of ballast, and the cost, including labour and coals at 12*s.* or 13*s.* per ton, averages about 1*s.* 4*d.* per cubic yard. Faggots will not give you the heat that coals will; but those who are accustomed to use them will be the best judges of their respective merits, and the cost of each in relation to any given effect. Spring and autumn are perhaps the two best seasons of the year for burning ballast. It is generally burnt in heaps, and in the moist condition in which it is dug from the ground; it is laid in layers round the heap, and when one is sufficiently burnt, fresh coal is spread over the surface, and another layer laid on. Your correspondent asks how large a quantity may be burnt at once, provided they have plenty of clay, (and I should think they had in "Clay-down") faggots, and workmen? I am not aware that there is any limit to the quantity they may burn at a time, or the size they may make their heaps.—*G. S. D.*

Yew Poisonous to Horses and Cattle.—I saw a horse opened that had died a few hours after eating Yew branches. The stomach was greatly inflamed, and the gullet also, where, here and there, a few leaves were sticking. Inflammation seemed to have set up speedily. The branches had been lying on the ground a few days. In the withered state the Yew is more actively poisonous. I have a pony now that has often eaten the tips of growing branches.—*Esle.*

Sawdust.—The following is the method of preparing sawdust for compost here:—To a large tank connected with the drain from the cattle strawyard and dunghill the sawdust is carted, and after being saturated in the tank with the drainings of the dunghill for several months, it is thrown out into a heap, and a quantity of lime-shells are mixed up with it—a layer of sawdust and a layer of lime-shells alternately. The wet sawdust slakes the lime, which acts as a stimulus to decompose the sawdust without greatly charring it. Not only sawdust, but ditch-scourings also, and the switchings of the hedges (and there are here above 20 miles in length of hedges, under the spade and knife) are prepared in this manner. The sawdust of resinous wood should be kept by itself, as there is scarcely any possibility of decomposing it.—*J. Drummond, Blair Drummond Gardens.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A Weekly Council was held, at the Society's House in Hanover Square, on Wednesday last, the 13th of March; present, Thomas Raymond Barker, Esq., in the chair, Thomas Alcock, Esq., R. Westbrook Baker, Esq., David Barclay, Esq., M.P., John Barton, Esq., William Baskford, Esq., W. R. Browne, Esq., French Burke, Esq., Henry Colman, Esq., A. E. Fuller, Esq., M.P., Humphrey Gibbs, Esq., Brandreth Gibbs, Esq., W. H. Hyett, Esq., John Kinder, Esq., Theodore Rathbone, Esq., Professor Sewell, William Shaw, Esq., Professor Solly, Samuel Staffurth, Esq., and William Stafforth, Esq. His Excellency Count Reventlow, the Danish Minister in London, addressed a letter to the Council in favour of M. Tesdorpf, a gentleman of large landed property in Denmark, who had come over to England for the purpose of making himself personally acquainted with the Agricultural improvements of this country; and for whom, on account of his high character and the active usefulness of his pursuits at home, His Excellency ventured to claim for him, as a distinguished foreigner, the favourable reception of the Society. The Council immediately admitted M. Tesdorpf to their sitting, and unanimously invited him to attend their Weekly Meetings whenever it might suit his convenience to do so during his residence in England. The following Gentlemen were elected Members of the Society:—

King, Frederick, Notcling, Southampton.
Turner, Thomas, (President of the Royal College of Veterinary Surgeons), Croydon.
Dowden, Thomas, Mitcheldever, near Winchester.
Percy, E. T., (Land-Surveyor), Sherborne, Dorset.
Farmiter, Edward, Beaulieu, Southampton.
Pearse, Thomas, Launceston, Cornwall.
Fothergill, Matthew, Cefnrachder, Badwelty, Newport, Monmouthshire.
Marjoribanks, Stewart, M.P., Bushy Grove, Watford, Herts.
Hodge, Henry, Boalstow Vale, Penzance, Cornwall.
Hawkins, Henry Montonnier, Tredunnock, Usk, Monmouthshire.
Walmsley, Thomas, Ribblesdale Place, Preston, Lanc.
Hopper, John Mason, Newham Grange, Stockton-on-Tees, Durham.

The names of ten Candidates for election, at the next Weekly Council, were then read.

Agriculture of Essex.—Mr. Pusey, M.P., chairman of the Journal Committee, announced to the Council the adjudication of the Society's prize of 50*l.*, for the best Report of the present state of the Agriculture of the county of Essex (stating the ordinary course of cropping adopted in the different soils of the county; the breeds of cattle, sheep, and pigs, most generally bred or fed within it; the state of its drainage; the implements used; the number of horses or other cattle employed in the different operations of husbandry; the tenure on which the farms are generally held; the wages of labour; the average amount of the poor's rate; and whether any and what alterations and improvements have been made in the system of Agriculture pursued within it since the Report made to the Board of Agriculture by Arthur Young, the Secretary to the Board, and published in the years 1807 and 1813)—to Mr. Robert Baker, of Writtle, near Chelmsford.

Weights and Measures.—The Marquis of Downshire communicated to the Council the great desire felt by the Royal Agricultural Improvement Society of Ireland to promote the establishment of a uniform system of weights and measures throughout the United Kingdom, for the sale of all Agricultural produce; in order to facilitate and increase as much as possible the free intercourse in commercial and Agricultural arrangements, between its three great integral portions, England, Scotland, and Ireland, reciprocally, &c. The noble marquis inclosed in his communication the particulars of the plan proposed by Mr. Blacker, of Armagh, to effect this desirable object; but as it appeared to be the ultimate result of Mr. Blacker's recommendations to establish the proposed uniformity by means of an Act of Parliament, the Council doubted whether, by the distinct legislative neutrality enjoined upon their discussions and proceedings, by the strict exclusive condition of the Royal Charter, they were at liberty to entertain the proposition; but agreed to receive the communications with thanks, and refer them to the decision of the monthly council.

Flemish Plough.—The old Flemish Plough procured as a present for the Society, by the late Rev. W. L. Rham, and imported by his executor David Jardine, Esq., having been released from bond in the Custom-House, was this day submitted to the inspection of the members. The high value set by Mr. Rham on the properties of this plough, for use in light lands, and the difficulty he experienced when preparing, for the Society's Journal (vol. ii. p. 58), his paper on the Agriculture of the Netherlands, in endeavouring to convey, by an engraved illustration, the peculiar curve of the sheet-iron turn-furrow, in which its excellence consisted, were the reasons which induced him to procure from the Continent an actual Flemish plough for the museum of the Society. This simple plough, says Mr. Rham, has been adopted or imitated in most countries, and for light soils without stones none can surpass it. The old Rotherham plough, which was improved by Small, was only a copy of it. In France and Switzerland it has almost superseded the old ploughs of the country wherever improvements have been introduced; and, with a few modifications, to adapt it to different soils, it has re-appeared in England as an improved plough.

Rotation of Soil.—Mr. Colman, the Agricultural Commissioner of Massachusetts, and at present engaged in an agricultural tour through Europe, having presented at the previous Council the model of a new implement, transmitted from Boston in the United States to this country by Mr. Isaac Clapp, for which the Council voted their best thanks and ordered all shipping charges to be paid, has laid before the Society Mr. Clapp's own account of his invention. This implement consists essentially of two rollers confined loosely on a fixed axle, and followed closely by an attached scarifier formed of a single row of strong tines. Mr. Clapp states:—"I have used this implement on newly-ploughed sward-land to great advantage. The greatest value which I consider it as possessing consists in the dispatch with which it works, and the perfect control it gives one over the soil, producing a rotation of soil which, in my opinion, is as advantageous as a rotation of crops. The working of the soil in rotation can be best effected by the use of the pulveriser, the second year, in place of the plough, leaving the sod to decompose; and then sowing Grass-seed, or a second crop, on the surface given by the first ploughing. If seeded to Grass the second year, and after the ground has acquired a sward equal to that first turned under, it may be then re-ploughed, bringing to the surface a vegetable mould that will insure an abundant crop without the aid of manure. By cultivating the soil in this manner, we have always one vegetable mould at work, and one at rest."

Trial of Manures.—Mr. Mowbray, of Glasham-house, Saxmundham, Suffolk, communicated to the Council the following result of his comparative experiments with manures:—"As the cost of manure is of essential importance to Farmers, an equality of price, or nearly so, has regulated their application, which took place on the same day, early in last March, and was followed by frequent rain. The cost of each sort, excepting that of the nitrate of soda (which was put on the land by mistake, at the rate of 28*s.* per acre), was about 16*s.* per acre, exclusive of carriage and sowing. The whole produce of Grass was weighed in my presence, on the day after it was mown and strown; therefore, the weight must be deemed to be that of Grass, not of Hay.

	Tons.	cwt.
Nitrate of Soda 131lbs., cost 28*s.* per acre, and produced	4	12
Sulphate of Ammonia 58½lbs, cost 18*s.* 6*d.*, and produced	4	10
Guano 131lbs., cost 16*s.* 7½*d.*, and produced	4	12
Carbonate of Ammonia 21½lbs., cost 18*s.* and produced	3	16
Saltpetre 42lbs., cost 16*s.* 6*d.*, and produced	3	3

Sulphuric Acid and Bones.—Mr. Evelyn Denison, M.P., communicated to the Council a statement he had received from Mr. Brackenbury, agent to the Earl of Scarborough, containing the result of his own trials of sulphuric acid and bones on sand land in Nottinghamshire, sown with Wheat, and on forest lands newly broken up, as well as of trials made by his Lordship's tenants, both with sulphuric acid and bones, and also bones alone. These results were in favour of the land on which the chemical preparation had not been used, and particularly so in reference to that on which bones only had been applied. Mr. Denison, wishing to make the experiment on strong clay Grass-land, less favourable commonly for the operation of bones than sand-land, thought it probable that the manipulation of the mixture of sulphuric acid and bones might make a considerable difference in the result, and he was therefore not deterred from the contemplated trial by the ill-success which had attended Mr. Brackenbury's applications. Still, however, he conceived it very desirable that more distinct particulars should be furnished, in reference, 1st, to the proportions of the sulphuric acid and bones; 2d, the quantity of water; 3d, the mode of mixing; 4th, the mode of application to Grass-land; and, 5th, the strength of the sulphuric acid itself, which is often sold in a diluted state for medicinal as well as chemical purposes.—Mr. Lloyd Walrond transmitted a copy of the fourth Report of the Gloucester Farmers' Club; Mr. Renton, a copy of the Report of the Newcastle-on-Tyne Agricultural Society; and Mr. MacNab, copies of his "North British Cultivator;" for all which and other communications thanks were ordered.—The Council then adjourned to Wednesday next, the 20th of March.

A Special Council was held on Thursday last, the 14th of March; present, the Rt. Hon. Earl Spencer, President, in the chair; Hon. G. H. Cavendish, M.P.; Sir T. Dyke Acland, Bart., M.P.; Col. Austen, H. Blanchard, Esq.; T. W. Bramston, Esq., M.P.; French Burke, Esq.; Col. Challenor, H. C. Compton, Esq., M.P.; H. Gibbs, Esq.; B. Gibbs, Esq.; W. H. Hyett, Esq.; Sir J. V. B. Johnstone, Bart., M.P.; J. Kinder, Esq.; G. Kimberley, Esq.; Sir R. Price, Bart.; Professor Sewell, J. V. Shelley, Esq.; and G. Wilbraham, Esq., M.P.

Southampton Meeting.—The report of Messrs. Shelley and Gibbs, the stewards and director who had proceeded, agreeably with the stipulations made with the authorities of Southampton at the last monthly council, to that town, for the purpose of selecting from the localities placed at the disposal of the Society, a suitable site for the Show-yards on the occasion of the ensuing county meeting of the Society in July. The Report having been read, the stewards and director present pointed out to the Council, on Lewis's large map of Southampton, the situation of a fifteen-acre field they had strongly and unanimously agreed to recommend for their adoption, as a piece of sound old park pasture land, near Portswood-lodge, nearly even in its surface, with a gentle slope to the south, situate midway between the town and the ground selected for the trial of implements, and only a few hundred yards from the old terminus of the line of the railway, which would be re opened for the occasion; and a tram-road being laid down from that point in the direction towards Portswood, all arrivals of stock and implements would at once be wheeled almost into the very Show-yard itself, with the least possible inconvenience to all parties concerned. The Council unanimously adopted this Report; and the President ordered a meeting of the General Southampton Committee, to be held on Thursday next, for the purpose of deciding on the plans to be recommended for the Pavilion and Show-yards, and for drawing out the proper specifications of contract for the works required.

ROYAL AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

At the meeting of the Council on March 7th, it was proposed that for the future, copperplate certificates, handsomely engraved, should be substituted for the Society's medals, to the Local Farming Societies, it appearing by the Secretary's returns that the sum for medals awarded last year amounted nearly to 200*l.*; that thereby a great saving would be made of the funds of the Society, which might be more beneficially applied, and the same effect produced.—Lord Erne, the chairman of the sub-committee upon Essays upon the best and most approved Plans for Cottages for the Working and Labouring Classes in Ireland, brought up the report, also signed by the Hon. C. J. Trench, and James L. W. Naper, Esq., which reported that they had examined the only essay on the subject, which had been sent in to the secretary; that the plans accompanying it were neatly executed, and their respective advantages, with the mode of building, explained in a clear and succinct manner; that the essay itself displayed

knowledge on the part of the author of the habits of the country and small farmers in the North of Ireland. The sub-committee were, however, reluctantly obliged to state that they did not think that the essay possessed sufficient merit to entitle it to the Society's medal.—The secretary was directed to communicate again with Mr. Smith, of Deanston, who, it was understood, was at present in this country, and to ascertain from him whether it would be in his power to undertake the task of personally inspecting the thorough-draining, executed by the four competitors for the Society's gold medal, who were selected at the last meeting of the council, for the purpose, on the principle of being the four who had executed the greatest quantity of thorough-draining amongst the different competitors.

FARMERS' CLUBS.

Bromsgrove District.—A meeting of this club was held in the Town Hall, Bromsgrove, on the 27th ultimo, E. F. Iddens, Esq., in the chair.—Mr. H. F. Fardon read a paper on Manures. He considered it impossible to obtain a clear and complete view of this subject without reference to principles. He adverted to the germination of a seed and the formation of a root and leaf,—the former intended to derive nutriment from the soil, the latter from the air. It is through the root that manures act on plants. This root consists of a fibre or fibres with a small spongiole at the extremity, which absorbs water containing the food of the plant in solution. All plants do not take the same ingredients from the soil, or the same quantities of different ingredients; but they generally absorb more or less of ammonia to supply nitrogen; carbonic acid to supply carbon; potash, soda, lime, magnesia, alumina, iron, manganese, silica, sulphuric acid, phosphoric acid, and chlorine. As the farmer takes his crop off the ground the soil becomes exhausted of particular ingredients, which must be restored by means of manure. It is of importance to the farmer to know what each crop abstracts from the soil, and by what kind and quantity of manure it may be best restored. For instance, Swede Turnips take 2651 parts of potash from the soil, while only 390 are absorbed by the same weight of Potatoes, and an acre of land will yield double the weight of Swede Turnips that it will of Potatoes. Turnips, therefore, exhaust the soil of potash more than Potatoes. Besides those manures which supply plants with food, there are others which improve the mechanical texture of the soil, and some act in both ways. *Farm-yard Manure.*—A considerable portion of this consists of straw, which thus restores to the soil the ingredients it has taken from it. The dung varies in composition according to the animal which afforded it, and to the food that animal received. The better the food the richer the manure afforded. The dung-heap should be formed under cover, that it may not be washed by the rain; but in that case it must be kept moist, and no liquid should be allowed to escape from it. To preserve this it might be well to form it on a stratum of soil. The gases given off during fermentation should also be preserved. The most important of these is ammonia, which, it is believed, may be retained by covering the surface of the heap either with gypsum or common salt, the heap being kept moist. Before we can decide how long the fermentation of the heap should be allowed to proceed, we must decide whether it is desirable to apply manure in a form to come into immediate action on the growing crop, or to give out its valuable qualities gradually to two or three successive crops. The former would appear to be the most economical plan, as in the latter case some of the valuable qualities of the manure might be wasted during the intervals between the crops. In the process of decay in the heap, nitrogen is converted into ammonia, and carbon into carbonic acid; and this process should be allowed to proceed to some extent, provided nothing is allowed to escape from the heap. Potash, soda, &c., remain in the manure after fermentation; but these and ammonia too may be washed away by water. Liquid manure may either be absorbed by the litter or collected in tanks. Where there is plenty of litter, the former is the best plan, as the application of the liquid is a troublesome operation. When collected in a tank, it should be allowed to ferment a little before application, and gypsum or salt might be useful to fix the ammonia. The animal and vegetable manures produced on a farm contain all the essential ingredients; but it may sometimes be desirable to apply particular nourishment in a concentrated form, or to apply something which should ameliorate in a greater degree the texture of the soil. These artificial manures act either directly, by furnishing food to the plant, or indirectly, by acting upon other ingredients in the soil to produce food. Guano is chiefly valuable on account of the phosphate of lime and ammonia which it contains, and sulphate of ammonia is also valuable from the latter ingredient. When applied to Grass-land early in the spring, at the rate of from 1 to 2 cwt. per acre, its effect is quick and powerful. Lime should not be mixed either with this manure or guano. Soot, night-soil, and nitrate of soda, are also valuable as furnishing nitrogen. There are other artificial manures, whose action depends on their containing one or more ingredients useful as food to plants.—A long discussion followed the reading of this paper, and resolutions were passed, "That well-fermented manure produces a speedy effect on the first crop, but long manure is most permanent in its action;" and "That salt is the most economical application for fixing ammonia in manure, which can be used in this neighbourhood; and that the Club recommends it for trial."—Mr. H. F. Fardon will read another paper, in continuation of the same subject, at the meeting in March.—*H. F. Fardon, Sec.*

Westbury and Newnham.—The first monthly meeting of this club took place on the 27th Feb. last. The subject of Mineral Manures, and the Inorganic Principles of Plants, was ably introduced by Mr. Henry Bird. Previous to entering upon the subject he stated that it was necessary to make some observations upon the soils of the neighbourhood. He stated the soils of that district to consist of several varieties, but all of them very productive if properly cultivated; and divided them into the stiff dark-coloured tenacious clay resting upon the lias limestone; the stiff red clay upon the soft red marl, extending to the red sand-stone, where the soil became lighter and more stony and dry; the rich alluvial soils found in the valleys and flat portions of that district, consisting of the detritus of a variety of rocks and decaying vegetable and animal substances, conveyed there through the agency of water; and lastly, the reddish-yellow soil resting on the magnesian limestone near the Forest of Dean. He next directed their attention to the nature and varieties of the neighbouring limestones used for building and agricultural purposes, pointing out the limes that contained iron and magnesia in large quantities, and those nearly free from the above substances. The Forest limestone, of a dirty reddish colour, contained a considerable quantity of iron and magnesia, as proved by the tests of those bodies; and he stated that it was unfit for agricultural purposes, except in small quantities, for Potatoes, and such crops. The Longhope limestone, of a bluish colour, and hard enough to scratch glass, contained iron, but no magnesia, and was composed chiefly of lime and flint, and was well suited for the stiff and red soils, which coincided with the farmers' experience who had used it. The Plumphill limestone, from the Forest, of a light drab colour, and smooth upon its surface, but very hard, contained a trace of iron, and no magnesia: it was extensively used for agricultural purposes. The lias limestone, at Awre, of a dark-blue colour, contained a little iron and no magnesia. He recommended this lime for dressing land, and a farmer present stated he had used it, and found it much superior to the Forest limestone. He then examined the red clays, pointed out their composition as being very productive; but from being wet and requiring draining, there were large tracts of that land in the district nearly unproductive from the neglect of it. The first principle upon stiff and wet lands was draining, for by that means the soil would be rendered more porous, and would admit the air freely after rain, as rain-water contained ammonia which, in passing through the soil, combined with it; and that was the chief cause why well-drained land so soon became productive. He then appealed to their experience, if cultivating land so wet as not to bear good pasture ever remunerated them for their trouble and expense. Next to draining, he stated the red soils required lime to render their iron inert and their consistency more porous, by disturbing the equilibrium of the soil, and to set the potash, which they contained, free; not for the purpose of bringing humus and vegetable fibre into a soluble state, for most of the red soils were deficient in that respect, so that after liming, farm manure was necessary to make up that deficiency. He concluded by stating that many of the farmers used green manure upon their stiff lands, which he considered a good practice, as the ammonia of the dung combined with the soil, and its straw contributed to make it lighter.—Charles Rosser, Esq., inquired the best means of restoring land that had been injured by magnesian limestone; to which Mr. B. suggested the manuring of it with diluted oil of vitriol (?) as gypsum would be formed, and the fixed air of the lime would unite with the magnesia and render it soluble and useful in the soil.—Another member inquired the best means of managing manure.—Mr. B. recommended it to be turned over with mould, common salt, and diluted oil of vitriol, and to be well covered with earth, as the nitrates of potash, soda, and lime, would form rapidly in it through the agency of the air; all of which substances were useful for the different crops.

On Tuesday, the 2d of April next, Mr. J. P. Smith will give a lecture at Newnham, on Artificial and other Manures, and their application to plants.—*S. R. S.*

Reviews.

Practical Hints to Practical Men, on New and Old Manures, &c. By J. D. Humphreys, Esq. Longman.

THE first half of this tract is in keeping with its title. We extract the following passage, which is usefully true:—

"How can the Farmer understand Manures unless he is a chemist? I answer—perfectly well, in the main, for the point with him is not what they are, but what they will do: it might as well be said, that he could not understand the benefit of a mutton chop, because he knows not the physiology of digestion.

"But again, it may be asserted, that the Farmer only understands the old forms of Manure, and that he has no more judgment of the new, than a sailor, landing on a foreign shore, has of its fruits,—to eat, may be to swallow poison! Very well,—but it is only so to a limited extent; for if the sailor has his wits on board, he will not eat, unless the fruit has some of the qualities of others which he has known, and which show it to be wholesome; and so the judicious Farmer will not use a new form of Manure, unless it contains the substantial qualities of the old, with new and peculiar advantages.

"It seems to have been expected, that the Farmer should become a practical student of organic and inorganic chemistry—an absurdity as gross, as to suppose, that every man should learn anatomy, because he may happen to break a limb, and need a surgeon."

But in the latter half the author forgets all this, and strings together a series of paragraphs in which he developes his peculiar views of the action of Manures, attributing it all to electric influence; in studying which, as the disciple of Sir H. Davy, he states, that he has "been so happy as to discover the governing principles of vegetable nutrition!"

This tract is apparently published as an advertisement of the "New Farmer's Compound," invented by the author. We advise its readers to pay especial attention to Mr. Humphreys's remarks on Farmyard Manure. "It is fit for all and everything:" and to depend more upon making and using a large quantity of this than on the purchase of the large quantities of artificial Manures—many of them no better than quack medicines—which now inundate the market.

Report of the Judges appointed to inspect the Farms entered for the Prize and Sweepstakes proposed by the Yorkshire Agricultural Society. 1843. J. Coultas. York.

WE notice this pamphlet for the sole purpose of extracting largely from it. It is republished from the Transactions of the Yorkshire Agricultural Society, and, containing condensed reports of good farming, it includes within its 16 pages more really useful matter than is often found in Agricultural works of many times its size. There were seven competitors for the Society's premiums within the prescribed district. The judges appointed to report upon the farms were Messrs. C. Howard, W. Pick, and R. Brough; and the following are some of the remarks they make before entering upon the work of description:—

"It may be proper to state, that after an extremely wet season, from the 4th May to 11th June,—during which important period for preparing the land for the reception of green crops, little or nothing could be done,—the weather changed to an almost equally remarkable drought. The cultivation of Turnips (and especially the Swedes) was in consequence extremely difficult, and the period of sowing was necessarily much delayed. This circumstance exemplified in a striking manner the advantage of always cleaning the land to the greatest extent the season will allow immediately after the harvest.

"Left to our own judgment as to the interpretation of 'the best cultivated farm,' we could only decide upon awarding the prize to the person who, in our opinion, adopted such a system, and carried out its practice in such a manner as, in the course of years, would tend to produce the largest amount of grain and animal food at the smallest expense per bushel and per pound. We think that *good* cultivation and *profitable* cultivation are synonymous terms, and that this applies alike to the Grass and to the arable lands."

They then proceed to describe the farms they visited—

"Mr. T. C. Johnson [to whom the first prize was awarded], has occupied the Chivet Grange farm [of 283 acres], 8 years. It is land of excellent quality, situate near Wakefield, and well adapted for the four-course system of cropping, which is pursued upon it.

"*Turnip Fallow.*—The cleaning of this commences as it ought to do, immediately after the harvest. In January or February it is covered, broadcast, with manure that has been previously led from the farm-yard (and to a considerable extent decomposed), at the rate of six tons to the acre. This is immediately ploughed in, and afterwards intimately mixed with the soil. The Turnip-seed is drilled in rows 18 inches apart, with 12 bushels of bones mixed with two quarters of ashes, or pulverised earth enriched with liquid manure. Sowing upon the level was evidently advantageous in the present dry season, and the advantage of early working, after the last harvest, was strongly exemplified by the clean and forward state of the land, notwithstanding the wet weather of May and June. Some of the Swedes are drawn, for the sheep to eat upon the Grass-pastures, but the greater part of the Turnips are consumed upon the land where they have been grown, more especially upon the lighter soil.

"*Barley* is drilled after the Turnips at the rate of 12 pecks to the acre; about two-thirds of the breadth are sown with 18 lbs. of White Clover, 3 lbs. of Rib-grass, and half a peck of Italian Rye-grass per acre, for sheep pasture. The remaining third is sown with 14 lbs. of Red Clover, and half a peck of annual Rye-grass per acre for mowing. This course prevents the too frequent repetition of Red Clover, as it thus comes into use only once in 12 years.

"*Wheat* is the principal crop after the Clover or pastured Grass, though parts of the latter are occasionally sown with Oats or Beans to vary the grain. Be the Corn-crop what it may, it is sown with the drill, and hoed both for the immediate purpose of encouraging the growth of the plant, and as a preparation for the succeeding Turnip-fallow.

"*Grass Land.*—In addition to the average annual pasture of about 40 acres of White Clover and Grass-seeds, this farm possesses about 100 acres of permanent Grass-land, of very good, though not prime quality. A portion of this is dressed every year with manure, sometimes supplied from the farmyard alone, but more generally enriched with a mixture of bones. Bones are used extensively on the Grass-land. They are purchased from the manufacturers of size, after having been boiled to extract the gelatine, and are obtained at one-third less price than those which have not undergone that process. Mr. Johnson is of opinion that their fertilising qualities are uninjured by the extraction of the gelatine, but in this opinion we cannot concur. Three quarters of these bones, mixed with three cart-loads of earth, and considered the proper dressing for one acre, and the period of application not material.

"Sixty or seventy acres have been underdrained with tiles, at an average expense of 4*l.* per acre. The work has been done by Sir W. Pilkington, for which, by agree-

meat, Mr. Johnson pays an interest of six per cent. upon the expenditure.

"*Linseed Cake* is used largely with great advantage as a substitute for Turnips in the farmyard; it is given to all the cattle. By this means the manure from the folds is doubled in value; and perhaps much of the superiority in bulk and luxuriance of all the growing crops may arise from this excellent practice. They were full and regular in every part. It has been observed that Mr. Johnson spreads his manure for Turnips over the land in January and February. This is a peculiarity in management. He keeps his fold-yard manure nearly 12 months before using it; as from the large size of his yards he is not obliged to take any manure out of them until the autumn; and to prevent too rapid a decomposition when carted into the field, it is closely pressed down in very large heaps, and protected from the air by a covering of earth. We might be inclined to doubt the advantage of keeping so large a stock of manure for such a length of time; but we cannot forget the unusual weight and fertility of the crops now upon the land." *(To be continued.)*

Miscellaneous.

Guano and Turnips.—As few subjects at the present day are more interesting to our agricultural readers than the comparative merits of manures on the various soils, we notice the following statement made by Mr. Vivian, M.P., as Chairman of the Swansea Farmers' Club. At the recent meeting of that club Mr. Vivian said "he would at present only allude to a trial which he had recently made of three manures with Swedish Turnips in a field near the Bryn. He had divided the field into three nearly equal portions, and had manured one part with farm yard manure, another with bone-dust; and the third with guano. The crops from the two first were good, that from the dung having rather more leaf than the other, but the guano crop which was in the centre of the field had failed entirely, from what cause he knew not. His farm-man stated that he had mixed sixty bushels of ashes with three hundred weight of guano, and that the manure was drilled in and covered with an inch and a half of soil under the seed. However the seed did not vegetate. At the same time he should mention that some Norfolk Turnips thrown in broadcast over the ground had done very well, showing that the guano was favourable to vegetation, but that it was ticklish stuff for the farmer to meddle with in Turnip crops. On grass land he had found it answer well. But where this and other artificial manures could be applied with the greatest advantage appeared to him to be on farms that were not easy of access, and where the land had been completely run out, such, for instance, as on the Clyne farm that he had lately taken. Grain crop after grain crop had been grown there, and the crop in most instances had been carried off the land. His difficulty was to make a start and provide keep for stock, so as to get yard manure. This he was endeavouring to do by growing Turnips and other green crops by means of artificial manures, and in such cases they might be valuable. But after all, the farmer's chief dependence for manure must be on his own farm-yard."—*Welsh Paper.*

[There is danger attending the *immediate* application of guano as a manure. It should be thoroughly mixed with the soil before the seed is put in above it.]

Caution to Farmers.—The following extract will show the danger and folly of the practice of keeping milk in zinc bowls, a custom which has lately become very prevalent, these articles being sold with the recommendation of a larger quantity of cream being produced, owing to galvanic action. "I would scarcely have believed," says Dr. Elaines, of Berlin, "that zinc vessels could again have come into use for holding fluids used for alimentary purposes, as Vauquelin forty years ago proved that such were certain, after a short time, to hold a considerable portion of zinc in solution. I have found by experience that a solution of sugar, which had stood only a few hours in the summer in a zinc vessel, contained a considerable amount of zinc salts. It has been often stated that the cream will separate more easily from milk if the latter be kept for a short time in a zinc vessel. As, however, it is known that milk will turn acid much sooner than a solution of sugar, it is the more to be apprehended that some zinc will be dissolved, and such milk will be the more noxious, as it is well known that even a small amount of zinc will cause violent spasmodic vomiting."—*Pharmaceutical Journal.*

Notices to Correspondents.

RURAL CHEMISTRY, By Edward Solly, Esq., F.R.S., Experimental Chemist to the Horticultural Society of London, Hon. Mem. of the Royal Agricultural Society, and Lecturer on Chemistry at the Royal Institution, has been reprinted from the *Gardeners' Chronicle*, with additions, and may be had of all booksellers, price 4*s.* 6*d.*

AGRICULTURAL IMPLEMENTS.—*An Emigrant.*—We cannot advertise tradesmen here. The best small charn we have seen is manufactured at Lewes, Sussex.

BRARING REIN.—*W. K.*—It is rarely useful.

BLUE LIAS CLAY.—*X. Y.*—Your soil is not suitable for Gorse. The scouring properties of the Grass in the months of August and September caused, we think, be owing to the presence of sulphur. We do not know to what to attribute it.

BURNT CLAY.—*F.* and *A Zummersetshire Man.*—See Home Correspondence.

CARROTS.—*An attentive Reader.*—If you have not sufficient yard manure apply 3 cwt. of guano per acre, broadcast, and harrow and scarify it well in before drilling the seed.

CLOVER DODDER.—*The Earl of Essex* will find that the seeds of the Clover Dodder are much smaller than those of Clover, and may be separated by the sieve. The size, No. 17, will answer the purpose. See p. 862, vol. iii, *Gardeners' Chronicle.*

DRAINING PLOUGH.—*C. W. S.*—The mole plough is generally worked by chain and capstan by two horses. If you pull it through the land by horses alone, you will need 10 or 12 if your soil be stiff. This mode of drainage answers well on Grass land.

FARM CAPITAL.—*A Farmer and Father.*—All the green food, &c. produced on the farm is consumed, in Mr. Morton's estimate, by sheep. You may consume as much as you like by other stock, and your doing so will reduce the stock of sheep, you will be able to keep, at the rate of about 12 sheep for every three-year-old ox or cow. Mr. Morton's estimate of the number of horses required for the farm is quite large enough. What kind of horses cannot be got for 80*l.* a-piece?

GRASS SEEDS.—*Presto.*—For a heavy soil, to remain down two years:—Perennial Rye-grass, 20 lbs.; Timothy, 1 lb.; Rough Cock's-foot, 3 lbs.; Meadow Foxtail, 2 lbs.; Meadow Fescue, 1 lb.; Red Clover, 4 lbs.; White Clover, 4 lbs.; Trefoil, 3 lbs.

GUANO.—*An Old Subscriber.*—Apply 3 cwt. per acre of it in the drills before setting the Potatoes, and work it well up with the mould by horse-hoeing, or otherwise. Sulphate of ammonia is sold by manufacturing chemists.—*Inquirer.*—3 cwt. per acre, mixed with as many cart-loads of earth, and spread some showery day. This is better than nitrate of soda, which is applied at the rate of about 2 cwt. per acre.

GYPSUM.—*Lancashire.*—Put four to six bushels per acre on your Clover.

ITALIAN RYE-GRASS.—*Suburban.*—Sow about 1½ bushel of Italian Rye-grass seed, and 12 lbs. of a mixture of ½ Red Clover, ½ White Clover, and ½ Trefoil, broadcast, per acre, on your Barley after it is up—say about the end of April; and if the Barley has been drilled hoe them in; if the Barley has been sown broadcast, harrow them in. See what liming your land, at the rate of about 80 bushels per acre, will do to restore the Clover in your meadow.—*J. Spratt.*—Sow it after the Barley is up, and hoe or harrow it in.

MANURE.—*J. N. V.*—You had better mix your blubber compost with the manure destined for Turnips, as you propose.—*J. McT.*—The sea sand on the north coast of Cornwall is a mass of pounded shells; 60 to 100 bushels are generally applied per acre. Your oyster shells will act equally well.—*Senex.*—Guano is more likely to be a useful manure than nitrate of soda. It contains a greater number of valuable ingredients.

MURRAIN.—*J. L.*—This disease appears to be a peculiar and remarkably virulent epidemic. In many respects, it is like the epidemic called *pleuro pneumonia*, but the ulcers along the neck and back are peculiar, and resemble putrid fever. You do not say if the disease has extended amongst the cattle of your neighbours; you say the lungs are black, but do not mention whether or not they are much heavier than common, or whether any portion sinks in water. The latter appearance denotes disease of some standing; the blackness of the lungs does not. Is there any effusion of water in the chest? The course of treatment indicated appears to be bleeding in the earliest stage, but with caution, and seldom repeated. If costiveness exists, a moderate dose of Epsom salts, followed by tartarised antimony, 10 grains. submuriate of mercury, 5 grains; powdered opium, 10 grains; nitrate of potash, 1 scruple; hydriodate of potash, 4 grains. The above may be mixed up with an egg, and a quarter of a pint of Linseed oil added. For a cow, four times the strength of the above will be necessary. The medicine may be given twice a day till the bowels are in a relaxed state, and then continued without the oil, but with gruel instead. Setons may be placed in the brisket, and blisters on the chest, and shelter, care, and nursing afforded. The ulcers should be dressed with a solution of chloride of lime. *W. C. S.*—*C. H. T.*—The *post mortem* appearances of the bodies in the fatal cases should have been mentioned. I have heard of no cases of this kind in which the feet are affected, becoming fatal in a few hours. I presume there must have been in those cases either organic disease, or the malady must have existed some little time before it was discovered. I should recommend, in many respects, the same treatment as that advised in the reply to the previous question, signed "J. L." The disease is probably principally in the chest, and if so, blisters on the sides and brisket will be necessary. The skin may be previously scalded, and one-half of the blister should consist of the ointment of iodide of mercury, and one half of the ointment of cantharides. It should be well and freely rubbed in. To the feet, a strong solution of sulphate of copper may be applied; and if fungus should appear, it should be touched, by means of a feather, with muriate of antimony. *W. C. S.*

POND MUD.—*S. S.*—Make a compost of it with lime, and put 20 cart loads per acre on your Grass. It ought to have been done in autumn. *FFFF*, in the plan you allude to, are the yards of the adjacent farmery.

SMALL FARM.—*T. Ridge.*—Trench your land, keeping the top soil uppermost. Your crops, after your plan, will be 8 tons of Potatoes, 18 of Carrots, and 25 of Mangel Wurtzel. Four cows would about consume the Potatoes and Mangel Wurtzel in six months, but your horses will not in that time have eaten more than three tons of the Carrots, if they have Corn too, so that you can keep more stock, and make more manure, and if you preserve the liquid manure too, you have no occasion to buy guano.

SPADE HUSBANDRY.—*Clericus.*—Dr. Yellowly is the best writer on this subject. We do not know the titles of his works. Order "Advice, &c." of any bookseller.

THE ROT.—*Gorys.*—"It is not likely to be true" that liming sheep pastures will cause the rot.

*** As usual, many communications have been received too late.

Second quality Beasts	3	2	—	3	6	Ewes and second quality	—	—	—	—
Calves	4	0	—	5	0	Pigs	3	8	—	4	6

Beasts, 2504; Sheep, 22,870; Calves, 74; Pigs, 410.

Again we have a very wet day and an increased supply of Beasts; the prices, however, do not suffer any diminution from Friday's quotation, there being a very good attendance of buyers. In some instances the best Scots have realised 4s 4d, but not generally; Herefords, Devons, &c., 4s 2d, and the short horns were of superior quality that sustained our highest quotation for that description. The supply of Sheep was still very short, which caused a brisk trade at a little advance. The very choicest Downs in some instances made 4s 8d, but this price was not general, the most selling Half-breds made 4s 6d, as did also the nicest selling Longwools. Calves are moderate in supply, but no advance in price can be observed, there is a brisk trade in this article, as also in Pigs.

FRIDAY, March 15.

Although the number of Beasts is much shorter than last Friday, we have to report a very dull trade, at rather lower prices. There being a great increase in the supply of Short horns, that description has suffered more, the very best scarcely making 4s 1od per 8 lbs, and the best Scots, &c., very little over 4s. The supply of Sheep is larger, but prices remain about the same, the very top for Downs, &c., being 4s 6d, and Longwools hardly reach 4s 4d. We notice several Lambs at market to-day, but the trade for them is hardly established yet, and the weather is against the sale of them; there is, however, a demand for the best qualities at about 7s per 8 lbs. The best Calves support Monday's quotations, but middling ones are a very heavy sale at less money; the prices of Veal range from 4s to 5s. Pork remains steady.

Beasts, 6081; Sheep and Lambs, 23,990; Calves, 128; Pigs, 380.

41, West Smithfield.

POTATOES.—SOUTHWARK WATERSIDE, March 11.

THE late snow-storm in Scotland prevented the loading of Potatoes for several days, the "Bread" was lost in our market, which occasioned a shorter supply than usual, and more money was consequently obtained; this trading in some measure to check the demand, yet, the weather being favourable for the consumption of Potatoes, and the supply unusually limited, the annexed quotations have been fully realised.

York Reds	-	-	70s to 80s	Kent and Essex Whites	- 60s	85s

Jersey and Guernsey Blues			70	—	Prince Regents and Shaws	70	75

WOOL.—BRITISH, FRIDAY, March 15.

One Market continues in pretty nearly the same state as it was reported last week. The present is considered a wholesome check, as prices were obliquely getting too high. Those who hold stocks now are willing to quit them, but not at a reduction on our last quotations.

Southdown Fleeces	1 0½	1 0				

James Forster, West Smithfield.

COVENT GARDEN, MAR. 15.—On account of the weather having been rather changeable during the week, the market has not been so well supplied, and trade has not been so brisk. Pine-apples are a little reduced in price; they are good in quality, and sufficient for the demand. We noticed a small quantity of good hothouse Grapes in the market; Portugals are good and plentiful. Desert Apples of good quality are scarce, as are also large Kitchen ones. Pears are likewise becoming scarce. Oranges are good and plentiful; they are slightly reduced in price. Lemons are nearly the same as last week. Chesnuts are a little cheaper. Strawberries continue to be brought in small quantities. Of Vegetables, Broccoli has been most plentiful; it is a little reduced in price. Savoys are getting scarce, and Brussels Sprouts are not so plentiful. Greens are selling at from 3*s.* to 6*s.* per dozen. Early Horn Carrots are excellent and sufficient for the demand; Turnips are likewise abundant. Seakale is offered at the same prices as last week; French Beans are tolerably well supplied; Asparagus is considerably advanced in price since our last report; it is selling at from 3*s.* to 15*s.* per 100. Rhubarb of excellent quality is abundant. Celery is getting scarce, and it is very inferior in quality. Cucumbers are nearly the same as last week. Cut Flowers chiefly consist of Combretum purpureum, Lachenalia tricolor, Gardenia radicans and florida, Epacrises, Heaths, Camellias, Scarlet Pelargoniums, Acacias, Azaleas, Lily of the Valley, Primulas, Fuchsias, and Roses.

FRUITS.

Pine Apple, per lb., 3*s* to 10*s*		Almonds, per pack, 6*s* to 7*s*	
Grapes, Portugal, per lb. 1*s* to 2*s* 6*d*		Sweet Almonds, per lb., 2*s* 6*d* to 3*s*

Brussels' Sprouts, p.h.-sv., 1*s* 6*d* to 2*s* 6*d*		Onions, 2*d* to 4*d* p. bush.	
Red Cabbages per doz. 2*s* to 3*s*		— Large, per bushel, 1*s* 6*d* to 2*s*	
Sorrel, 1*s* to 1*s* 6*d* p. hf.-sv.		— Spanish, per doz., 1*s* to 2*s*	
Asparagus, per 100, 3*s* to 16*s*		— pickling, p. hf.-sv., 2*s* to 3*s* 6*d*	
Seakale, per punnet, 1*s* to 3*s*		Shallots, per lb., 4*d* to 6*d*	
French Beans, 2*s* to 3*s* per 100		Lettuce, Cabb., p. score, 6*d* to 1*s*	
Autumn Potatoes, 8*d* to 6*d* per lb.		Celery, per bun., 6*d* to 8*s*	
Savoys, per doz. 6*d* to 1*s* 6*d*		Mushrooms, per pottle, 1*s* 6*d* to 2*s*	
Greens, per doz. 3*s* to 6*s*		Walnuts, per bushel, shelled, 16*s* to 20*s*	
Potatoes, per ton, 60*s* to 85*s*		Small Salads, per punnet, 3*d* to 6*d*	
— per cwt., 2*s* 6*d* to 4*s* 6*d*		Watercress, per doz. sm. bun. 2*d* to 3*d*	
— per bushel, 1*s* 6*d* to 2*s* 6*d*.		Parsley, per doz. bunches, 3*s* to 4*s*	
— Kidney, p. bush., 2*s* to 3*s* 6*d*		Tarragon, Green, per bun. 4*d* to 6*d*	
Turnips, per doz. bunches, 1*s* 6*d* to 2*s*		Endive, per score, 1*s* 6*d* to 4*s*	
Red Beet, per doz., 6*d* to 1*s*		Green Mint, 4*d* to 6*d* per bunch	
Horse Radish, per bundle, 1*s* to 6*s*		Marjoram, green, p. doz. bun. 1*s* 6*d* to 2*s*	
Radishes, spring, 10*d* to 1*s* 3*d* p. pun.		Chervil, per punnet, 3*d* to 6*d*	
Carrots, p. doz. bun., 3*s* 6*d* to 4*s*		Salsafy, per bundle, 1*s* to 1*s* 6*d*	
Cucumbers, 2*s* to 4*s* each		Scorzonera, per bundle, 1*s* to 1*s* 6*d*	

MARK LANE, FRIDAY, MARCH 15.—The arrivals of Grain and Flour during the week have been small, owing in some measure to the boisterous weather. Having a very thin attendance at Market this morning, business in all kinds of Corn was extremely limited; nor do we observe any alteration in their value.

JAMES FOSTER.

BURBIDGE AND HEALY beg respectfully to inform the Horticultural world that they are quite ready to supply their new BOILER, of every size. They have now fixed a sufficient number to warrant them in stating that what they put forth as the qualities of their Boiler and Furnace arrangement may be perfectly relied upon: they have put up one at the Horticultural Gardens, where B. and H. believe it is considered to answer as represented; they have also fixed it in connection with a new description of Iron Tank, which combines the qualities of the round pipe and the open tank, which may be pronounced the perfection of a Heating Apparatus for Horticultural purposes, particularly for Graperies, Epiphyte-houses, Melonpits, &c., &c. The arrangement is such that any gentleman or gardener may have the whole constructed so as to be put together with the greatest facility by the gardener, first sending a correct plan to 130, Fleet-street. A Prospectus may be had detailing the prices, &c.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 372, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 372, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

WIRE-WORK, HOT-WATER APPARATUS, GREEN-HOUSES, &c.

ST. THOMAS BAKER, MANOR-HOUSE, MANOR-PLACE, KING'S-ROAD, CHELSEA, Manufacturer of INVISIBLE WIRE FENCE, to resist Grazing Stock, and rendered Rabbit-proof. WIRE-WORK in Trainers, Arches for Walks, Bordering, Flower-stands, Pheasantries, &c. HORTICULTURAL BUILDINGS, Green and Hothouses, Conservatories, &c. The same heated by HOT-WATER APPARATUS, on improved and economical principles.

Parties waited on in Town or Country, and Drawings and Estimates free. Work for the Trade as usual.

Ward's Cases, or Domestic Greenhouses.

GUANO ON SALE BY THE IMPORTERS,
JOHN BOYD & Co.,
Wellington Chambers, London-bridge, Borough.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS,
ANTONY GIBBS AND SONS, LONDON;
WM. J. MYERS AND CO., LIVERPOOL;
And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, March 16, 1844.

GUANO, PERUVIAN, &c.—The above Manures, also Potter's Guano, Nitrates of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.

Lists of Prices, with Synopsis of mode of use, on applications to MARK FOTHERGILL, 40, Upper Thames-street, and 5, Railway Place, Mark-lane, London.

MANURES FOR WHEAT, &c.

POTTER'S GUANO.—Result of an Experiment on Wheat, tried near Colchester—sown Nov. 1842, reaped August 1843. POTTER'S GUANO.—Seven bushels per acre gave 54½ bush. Grain. Daniell's Manure, 40 bush. per acre, gave 46 bush. Grain. Difference in favour of POTTER'S GUANO, 8½ bush.

Note.—The Daniell's Manure cost 3*l.* POTTER'S (present price) 2*l.*—Works 28, Upper Fore-street, Lambeth; sold by M. FOTHERGILL, 40, Upper Thames-street.

BEAUTIFUL FLOWERS. — POTTER'S CONCENTRATED LIQUID GUANO, for Flowers, Kitchen Garden Produce, &c. Sold by appointment, by SAVORY and MOORE, Chemists to the Queen, 130, New Bond-street, and 220, Regent-street, and can be had of most respectable Chemists and Seedsmen. Price 1*s.* 9*d.* the quart bottle, with directions.

DR. LINDLEY, in the *Gardeners' Chronicle* for 1843, p. 560, says—"POTTER'S GUANO will convert your desert into a paradise." And in the Number, Feb. 10, 1844—"POTTER'S GUANO is unrivalled."—Works, 28, Upper Fore-street, Lambeth.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing a more rapid vegetation in Plants than any substance known. It may be had at Mr. LAWES' Factory, Deptford Creek, price 7*s.* per cwt.

Phosphate of Potash,	15*s.*	per cwt.
,, Soda,	12*s.*	,,
,, Magnesia	9*s.*	,,
,, Ammonia	1*s.*	per lb.

THE URATE of the LONDON MANURE COMPANY, 5*l.* per Ton. It is with the greatest satisfaction, after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By promoting a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops. The Urate may be sown broadcast, or which is preferable, by the drill, at the rate of one ton to three acres, and it is desirable it should not be placed more than two inches below the surface. As a top-dressing for Wheat the Urate has been used with great advantage. Gardeners and Florists will find it very useful for Dahlias and other roots. Full particulars and Testimonials will be forwarded on application. Genuine Peruvian Guano; Phosphate and Sulphate of Ammonia; Gypsum and every other artificial Manure.

EDWARD PURSER, Secretary, 40, New Bridge Street.

IMPORTANT TO AGRICULTURISTS AND OTHERS.

ANALYSES OF SOILS, MANURES, &c., are conducted by Mr. MITCHELL, Analytical Chemist (late of the Royal Polytechnic Institution), No. 5, Victoria Cottages, Rawley Road, Kentish Town.

A vacancy now occurs for one house or outdoor Pupil, for the study of Chemistry as applied to Agriculture. Apply as above.

TO AGRICULTURISTS.

THE Dry Material for making CAMPBELL'S CORN-PRODUCING LIQUIDS, or FERTILISING STEEPS, which have arrested the attention of Agriculturists in all parts of the United Kingdom, is now to be had in Boxes containing quantities for 5 Gallons and upwards, at the following prices:—

For WHEAT, Material per Gallon	2*s.* 6*d.*
,, OATS and GRASSES,	1 6
,, BARLEY,	2 0
,, BEANS and PEASE,	2 3
,, TURNIPS and RAPE SEED	2 6

Agents in London:—Mr. EDWARD PURSER, 40, New Bridge-st.; Messrs. GEO. GIBBS and Co., 26, Down-st., Piccadilly; and Messrs. THOMAS GIBBS and Co., Corner of Half-moon-street, Piccadilly.

TO AGRICULTURISTS.
ENGLAND INDEPENDENT OF THE WORLD FOR CORN.

THE attention of the Agricultural Interest, at this momentous crisis, is requested to the great importance of LIQUID MANURE, and the ease with which it may be appropriated, by the use of FOWLER'S PUMPS, made expressly for the purpose, either portable or fixed; Garden, Ship, and Barge Pumps; also, those for Distillers, Brewers, Soap-boilers, and Tanners, for hot and cold liquor. Pumps kept for Hire, for Excavations and Wells, Buildings heated by hot-water, for Horticulture, and every variety of manufacturing purposes. The trade supplied on advantageous terms, by BENJAMIN FOWLER, Engineer, &c., 63, Dorset street, Fleet-street, London.

GLASS SUPERSEDED for HORTICULTURAL PURPOSES by WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, rendering Muslin, Calico, or Linen, for the Frames of Greenhouses, Pine, Melon, or Cucumber Stoves, &c., impervious to rain or moisture, admitting light equal to Glass, much warmer, and the plants never burn under it.

Noblemen, Gentlemen, and Gardeners will, by using this composition, have the only effectual protection for their Fruit-trees during the blooming season; it is a certain defence from frost, sleet, wind, and blight; its transparency admits the general beams of the sun, with abundance of light, which causes the bloom to expand with increased luxuriance, the fruit to set and swell more freely, much earlier, and a crop of fruit to any extent may be warranted. The covering not to be moved by day (except to thin the Fruit, which will be necessary), till the month of June. It is recommended that the Calico be prepared early, so as to be thoroughly dry before using.

Sold in Bottles, with directions for use, pints, 2*s.* 6*d.*, quarts, 4*s.* 6*d.* each. One pint is sufficient to coat four Frames twice over, each Frame to be 5ft. by 3ft. 3in., or thereabouts. Prepared by GEORGE WHITNEY, Chemist, Shrewsbury. Seedsmen, Florists, and Merchants supplied by Mr. W. BAILEY, Chemist, North-street, Wolverhampton. Appointed Agents:—Messrs. BUTLER and MUCKLEY, Covent Garden, where a sample of prepared calico may be seen; Mr. WATKINSON, Market-place, Manchester; PAGE and SON, Southampton; T. and C. WHALLEY, Nurserymen, Liverpool.

Agents wanted for London and the country.

YORKSHIRE LAND-DRAINING ASSOCIATION.
Capital, 500,000*l.*, in stock of 25*l.*—Deposit, 5 per cent.

PATRONS.—The Right Hon. Lord Beaumont.
The Right Hon. Lord Viscount Morpeth.
Sir William M. Milner, Bart.
Edward Stillingfleet Cayley, Esq., M.P.

PROVISIONAL COMMITTEE.

Mr. James Andrew, Kirkham Cottage, Wakefield.	J. Bailey Denton, Esq., 9, Gray's-inn-square, London.
Mr. Caleb Angus, Newsick, Driffield.	John Grey, Esq., Dilston.
J. Barkerridge, Esq., Bretton, Wakefield.	Mr. Edwin Green, Havercroft, Barnsley.

	Mr. William Take, Bradford.

With power to add to their number.

BANKERS.—The York City and County Banking Company.
STANDING COUNSEL.—H. Bellenden Ker, Esq., Lincoln's-inn.
DRAINING ENGINEER.—James Smith, Esq. (Deanston.)
SOLICITORS.—Messrs. Blanchard, Richardson, and Gurch, York.
SECRETARY.—John H. Charnock, Esq., Wakefield.

This Association is formed for the purpose of affording to the Agricultural Interest, by means of its collective capital, the funds necessary for the THOROUGH DRAINING OF LAND; and of executing and superintending the execution of the works required for this purpose on the most economical and effective principles—repayment of the money advanced to be made, with interest, by such equitable half-yearly instalments as in the several cases may be determined.

Among the various objects to which of late years collective capital has been more or less successfully applied, it is not a little surprising that the one which, of all others, offers the most certain and profitable return, with the soundest security, should have hitherto been almost disregarded. The time, however, has arrived, when an urgent desire for Agricultural improvement on the one hand, and a dearth of safe and profitable investment for superabundant capital on the other, renders such an Association highly desirable to both the landed and monied interest, whilst to the community generally an almost incalculable advantage will be secured by a proportionate increase of labour and food.

At a meeting of the council of the Yorkshire Agricultural Society, held in York, on the 29th of December, 1843, a resolution was passed, approving generally of the objects of this Association, and at the monthly meeting of the Wakefield Farmers' Club held on the 5th January, 1844, a resolution approving of the principle and objects of the Association, was unanimously adopted.

At the meeting of the Royal Agricultural Society of England, at Liverpool, in July, 1841, Lord Stanley remarked—that "there was no bank in the whole country—no commercial speculation—no investment so safe, so sure and profitable, as that in which even borrowed capital may be engaged, by investing it under the ground of your own soil." And in reference to this Association, his Lordship, in a letter to the Committee says:—"I am fully satisfied of the benefits which such an Association is capable of conferring on the country, if confined to its legitimate object—the lending of capital on the security of an investment in draining; and I think it very probable that many landed proprietors would avail themselves of the facilities afforded by an institution lending money on land, repayable by instalments—a condition on which few private parties are willing to lend.

Bearing in mind the important objects of the Association, and the perfect security with which its operations can be conducted, at a comparatively trifling expense (no large expenditure for previous outfit being required), it may be reasonably expected that the return for the capital embarked will be such as to insure the support of prudent and permanent investors, thereby divesting it of that speculative character which has stigmatised so many modern projects, and which it is the especial desire of the Committee to avoid.

Application for prospectuses, and further particulars to be addressed to the Solicitors, Messrs. BLANCHARD, RICHARDSON, and GURCH, York; or to J. H. CHARNOCK, Esq., the Secretary, Wakefield.

ASPHALTUM in its pure state, with all the material and instruction how to prepare, or if required, the labour performed at a moderate charge.—Apply to J. A. HEBBARD and SON, 20, Harp-lane, Tower-street. All Letters prepaid.

CHOICE FLOWERS and PLANTS in POTS.

HUMPHREYS'S COMPOUND, applicable to all Greenhouse Plants, to Melons, Cucumbers, &c., and to promote the germination of Seeds. Sold in bottles 1*s.* 9*d.* each, by [illegible] and SON, Mansion-house-street; HURST and MCMULLEN, Leadenhall-street; W. CLARK, Bishopsgate-within; SMITH, Islington Nursery; GRIMSLEY and Co., Covent Garden; BATT and RODLEY, 412, Strand; WILLIAM and JOHN NOBLE, Fleet-street; SMITH, Covent Garden; CHARLWOOD, Tavistock-row; W. J. NUTTING, 46, Cheapside; G. LAWRENCE, 18, Piccadilly; JOHN KERNAN, Great Russell-street, Covent Garden; LOCKHART, 136, Cheapside; SKUTTLEWORTH, Pantheon; MINIER, ADAMS, and NASH, 63, Strand; THATCHER and SON, Islington; J. FRYER, Clarendon-terrace, Camberwell; THOMAS ANSELL, Camden Town; THOMAS WATKINSON, Market-place, Manchester; T. S. KING, Rochester; W. E. RENDLE, Plymouth; DICKSON and Co., Edinburgh; POWNEY, Leeds; FISHER, HOLMES, and Co., Sheffield; P. LAWSON and SON, Edinburgh; J. THORNE, Shepton Mallet; and other leading Seedsmen in town and country. Wholesale Agents, DAVY, MACKMURDO, and Co., 100, Upper-Thames street, London.

AGRICULTURAL IMPROVEMENT.

SPRING WHEAT.—HUMPHREYS'S FARMERS' COMPOUND, manufactured on a *new principle*, so as to present a cheap manure of greater power, and more extensive usefulness, than the guano; and without its caustic rankness, and liability to be washed out of the soil. From its wholesome character, it is unrivalled for garden culture; and as a Top-Dressing for all Spring Crops. Per acre, for WHEAT, BARLEY, &c., with a bad soil, *Five cwt.*; with better land, *Three* or *Two*. GRASS on the average, *Two cwt.* TURNIPS, THREE or TWO. Price 12*s.* per cwt. Agents, DAVY, MACKMURDO, & Co., Manufacturing Chemists, 100, Upper Thames-street, London.

CHOICE FLOWERS AND PLANTS IN POTS.

HUMPHREYS'S INDOROUS SOLUBLE COMPOUND. A few grains dissolved in water, and used occasionally, are effective. For list of Agents see other Advertisement.

TO COLONISTS, AGRICULTURISTS, &c.—Mrs. MARY WEDLAKE, widow of the late Mr. THOMAS WEDLAKE, of the Original Iron-foundry and Agricultural Implement Manufactory, established forty years, at Hornchurch, near Romford, Essex, and of 118, Fenchurch-street, London, begs to inform the friends of her late Husband that she continues to Manufacture all kinds of Agricultural Implements, for the invention of which he was so often honoured with the medals of the Royal Society of Agriculture, and which obtained for him so high a distinction among the Farmers of England and British Colonists. Being assisted by men of talent in the Manufacture of these articles, she is in hopes of deserving the high repute this Establishment has so long enjoyed, and now solicits respectfully a continuance of the patronage of the numerous friends of her late husband. The following articles, made in a very superior manner, are kept on sale at the London Warehouse, 118, Fenchurch-street, viz.:—

Patent Hay-making Machines	Subsoil Ploughs
Winnowing Machines	Horse-power and Hand-thrashing Machines
Dressing Machines	Patent Horse Rakes
Patent Chaff-cutting Machines	Scarifiers
Oil-cake Crushers	Drills of all kinds
Double-action Turnip Cutters	Park Fencings, Hurdles
Flour Mills	Furnace Bars
Bean Mills	Cast Iron Horse Racks
Railway Wheels, Vacuum Pumps	Kitchen Ranges
Patent Essex Ploughs, 30 different sorts	Stoves, Fenders

*** Castings to any pattern.

☞ *For a more detailed List, see Johnson and Shaw's "Farmers' Almanack" for 1844.*

Please to be particular in the address, Mrs. MARY WEDLAKE, 118, Fenchurch-street, London; or, Original Iron Foundry, Hornchurch, Essex.

AGRICULTURAL PROTECTION SOCIETY.—
PRESIDENT—The Duke of Richmond.
VICE-PRESIDENT—The Duke of Buckingham and Chandos.

TRUSTEES.

The Duke of Norfolk	The Duke of Cleveland
The Duke of Rutland	The Earl of Yarborough

GENERAL COMMITTEE.

Mr. Allen, M.P.	Mr. Plumtree, M.P.	Mr. Fisher Hobbs
Mr. Brandon, M.P.	Mr. Pusey, M.P.	Mr. P. Matthews
Lord Beaumont	Hon. F. Scott, M.P.	Mr. J. Mills
Mr. Bell, M.P.	Sir J. Trollope, M.P.	Mr. J. Jonas
Mr. Buck, M.P.	Hon. T. Vesey, M.P.	Mr. D. Maidwell
Mr. Caley, M.P.	Mr. Wodehouse, M.P.	Mr. G. Shackell
Mr. Beckett Denison, M.P.	Lord Worsley, M.P.	Mr. Pope
	Mr. Allnatt	Mr. Trower
Mr. R. Gordon	Mr. J. Bennett	Mr. R. Trumper
Lord Henniker, M.P.	Mr. Bethell	Mr. Thomas Umbers
Visc. Ingestre, M.P.	Mr. Copeland	Mr. S. Wade
Mr. W. Mills, M.P.	Mr. Thomas Ellman	Mr. Warsop
Mr. Newdegate, M.P.	Mr. Ellis	Mr. T. Woodward
Mr. S. O'Brien, M.P.	Mr. Greetham	

1. That a Society, to be called the Agricultural Protection Society for the United Kingdom of Great Britain and Ireland, be now formed, for the purpose of upholding, by constitutional means, protection to British Agriculture.

2. That the object of this Society is to maintain protection to British Agriculture, not less than that at present existing.

3. That the Society shall, through the press, repel the imputations and point out the incorrectnesses contained in the statements of those who oppose such protection.

4. That party politics shall not be introduced into the proceedings of this Society, and that the Society shall on no account interfere in any election for a Member to serve in Parliament.

5. That the affairs of the Society shall be managed by a President, Vice-President, four Trustees, and a Committee of 40 Members, whereof 26 shall always be tenant-farmers; and that Chairmen or Vice-Chairmen of County Societies connected with this Society shall be ex officio members of this Committee, and that the said Committee shall have power to add to their numbers.

6. That any funds contributed by such Country Societies or individuals be paid into the Bank of England, to the credit of the Trustees of the Agricultural Protection Society for the United Kingdom of Great Britain and Ireland.

7. That the publications of the Society be issued on reduced terms to Country Societies which have contributed to its funds.

8. That a donation of not less than 5*l.*, or an annual subscription of not less than 1*l.*, shall constitute every person who shall agree in the principles of this Society one of its members.

9. That there be an Annual Meeting of the Society in the month of December, notice of which shall be given in the London papers three weeks previously.

10. That the meeting of the General Committee shall take place, except as hereinafter stated, on the first Tuesday of every month, to receive and take into consideration the reports of the different Sub-committees.

The next meeting of the General Committee will take place on Friday, the 22d inst., at Eleven o'clock, at 51, Portland-place.

(Signed) RICHMOND, President.
W. MILES, Hon. Secretary.

FLORTICULTURAL FETE IN LONDON.

Grosvenor and [illegible] Gardens, 12th June, 1844.

The Society distributes the following Medals and Rewards, viz:—

		£	s.	d.
G.	Gold Medal	10	0	0
SG.	Silver Gilt Do.	5	0	0
S.	Silver Do.	3	0	0
SB.	Silver Banksian Do.	2	0	0
B.	Bronze Medal Do.	1	0	0
GE.	Gold Elizabethan Do.	7	0	0
GG.	Gold Grecian Do.	5	0	0
GK.	Gold Knightian Do.	10	0	0
LG.	Large Gold Do.	20	0	0

Exhibitors to whom any of these shall be awarded can exchange them one for another, or may receive their value in money, or in plate. In case an Exhibitor shall receive a First Prize in any one Letter, he shall not be entitled to receive any other Medal in the same Letter, except in *CC*, *DD*, and *EE*.

CLASS I.—FLOWERS; for which Nurserymen and Private Growers exhibit independently of each other.

A. Pelargoniums, in collections of 12 new and first-rate varieties, cultivated with superior skill, in pots of 24 to a cast. GB—SG—LS—SK.

B. Pelargoniums, in collections of 12 varieties, in pots of 12 to a cast. SG—LS—SK

N.B. Persons exhibiting in *B* cannot also exhibit in *C*.

C. Pelargoniums, in collections of 6 varieties, in pots of 6 to a cast. LS—SB

D. Rhododendrons, in pots; not fewer than 6 plants, in 6 varieties LS—SK—SB.

E. Roses, in pots; Amateurs to show in collections of 12, Nurserymen in collections of 25, distinct varieties. GB—SG—LG

N.B. It is the wish of the Society in a future season, to require Roses to be shown exclusively in pots; and not to allow cut specimens to be exhibited at all.

F. Moss Roses in loose bunches, so as to exhibit, as far as possible, the habit of the variety; in 12 varieties. SK—SB—C

G. China Roses, exhibited as in the last letter, and in 50 varieties. LS—SK—B—C.

N.B. No one who exhibits in this letter can also compete for the following.

H. Other Roses, exhibited as in the letter *F*, and in 25 varieties. SK—SB—C.

N.B. Higher medals than those here offered for Roses cannot be given by the Judges. And if Roses are brought for exhibition without attention to the regulations here explained, they will not be allowed to be placed on the tables.

I. Cape Heaths, in collections of 20 distinct varieties. GB—SG—LG.

N.B. It is expected that the same plant shall not be exhibited on more than one occasion

K. Cape Heaths, in collections of 6 distinct varieties. SG—LS—SK.

N.B No person who shows in *I* will be allowed to exhibit also in *K*

L. Calceolarias, in sixes; in pots of 12 to the cast LS—SK—SB.

M. Carnations, in pans of 24 distinct varieties. LS—SK—SB.

N. Picotees, in pans of 24 distinct varieties LS—SK—SB.

O. Pinks, in pans of 24 distinct varieties. SK—SB.

CLASS II.—FLOWERS, for which all persons are admitted to equal competition.

P. Stove or Greenhouse Plants, in collections of 30 plants. GK—GB—SG—LS.

N.B. Heaths, Calceolarias, Fuchsias, Greenhouse Azaleas, Rhododendrons, Orchidaceæ, Cacti, and Pelargoniums, to be excluded from *P*, *Q*, and *R*.

Q. Stove or Greenhouse plants, in collections of 15 plants. GB—SG—LS.

N.B. Persons exhibiting in *P* not to compete in *Q* also.

R. Stove or Greenhouse plants, in collections of 6 distinct species SG—LS—SK.

N.B. Persons exhibiting in *P* or *Q* will not be allowed to compete in *R* also.

S. Greenhouse Azaleas, in 12 distinct varieties. GB—SG—LS.

T. Greenhouse Azaleas, in 6 distinct varieties. SG—LS.

N.B. No one can show in both classes of Azaleas.

U. Stove or Greenhouse climbers, in collections of 6 species. SG—SK.

V. Exotic Orchidaceæ, in collections of not fewer than 20 species. LG—GE—GB

N.B. Exhibitors cannot show in more than one of the classes, *V*, *W*, and *X*.

W. Exotic Orchidaceæ, in collections of not fewer than 6 species GE—GB—SG.

X. Exotic Orchidaceæ in single specimens SG—LS—SK

Y. Plants in glass cases, grown on Mr Ward's plan. SG—LS—SK.

N.B. It is highly desirable that these cases be made with a moveable door, so as to prevent the condensation of the water on the inner face of the glass during the time of exhibition.

Z. Distinct varieties of Tall Cacti in flower. GB—SG—LS.

N.B. The GB and SG Medals are not to be given if fewer than six varieties are exhibited.

AA. Fuchsias in collections of 12 distinct varieties. LS—SK.

BB. Cinerarias, in pots, in collections of 12 distinct varieties. SK—SB.

CC. Single specimens of new or extremely rare ornamental plants. BG—LS—SK—SB—C.

N.B. These Medals will be awarded by the Society's Officers, and not by the usual Judges. Exhibitors will particularly observe that none but new or rare plants can be exhibited under this letter. *Nothing will be regarded as new which has been exhibited in the Gardens in a previous season*

DD. Miscellaneous subjects. SK—SB—C

N.B. Cockscombs, Heartsease, Hydrangeas, and cut flowers, are altogether excluded from exhibition. Exhibitors under this head will not be thereby *entitled* to a pass ticket.

EE. Seedling Florists' flowers. SK—SB—C.

N.B. Every seedling must be shown singly, and must be marked with the name it is to bear. The same seedling cannot gain a prize more than once in the season Pelargoniums are to be shown in pots, and not in a cut state. No person will be allowed to exhibit more than five seedlings at each meeting. Exhibitors under this head will not be thereby *entitled* to a pass ticket.

In Addition to any medals assigned to the classes *I*, *P*, *Q*, and *W*, the SK and SB medals are offered for the two collections in those classes which shall be best named by the Exhibitor.

N.B The Society's officers, who will make this award, will be guided in their judgment by a consideration not only of the correctness of the names, but of the accuracy and the spelling, and the neatness of the writing.

CLASS III.—FRUIT, for which Market Gardeners, Fruiterers, or persons in the habit of regularly supplying the market, and private growers, exhibit independently of each other.

N.B. All fruit must be FULLY ripe and WELL-COLOURED; if the contrary it will be disqualified.

FF. Miscellaneous collections of Fruit, consisting of at least three different kinds, Peaches and Nectarines being considered as only one kind. GE—GB—LS.

N.B. Cucumbers, Tomatoes Gourds, and similar Kitchen Garden produce, are excluded from this letter.

[illegible] Grapes. SG—LS—SK

HH. Pine-apples. SG—LS—SK.

II. Peaches or Nectarines. SG—LS—SK.

KK. Other kinds of Fruit. SG—LS—SK.

Judges.—The Judges have been selected for their knowledge of Horticulture, and the number and value of the prizes awarded by the Society for particular [illegible] Gardener, and in these publications, if [illegible] Gardeners' Chronicle.

It is also requested to be borne in mind that the Society's Medals are offered for other and [illegible] objects, than for fine specimens of Horticultural skill, the design of the Council in instituting these meetings being not so much to encourage the collector as to reward the skilful Gardener; they are also not to make any award in cases where the objects exhibited do not appear worthy of a Medal; otherwise a bad single exhibition might obtain a prize, merely because there is no better exhibition of the same class to oppose it.

Copies of the above list may be obtained at 21, Regent-street, upon application to the Secretary.

FASTOLFF RASPBERRY.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, THE MOST NOBLE THE MARQUIS OF AILSA, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c &c, as well as by the HORTICULTURAL SOCIETY OF LONDON.

YOUELL AND Co. have much pleasure in announcing they are now supplying Fine Canes of the above highly-valuable and much-esteemed RASPBERRY, unequalled for the extraordinary size of its fruit and richness of flavour

Those to whom Y. and Co sent it last season have expressed their high admiration of its superiority over all other varieties, and has been awarded several prizes from various Horticultural exhibitions during the season As a proof they have not exaggerated its excellent qualities, fruit was submitted to Dr. LINDLEY, (*see Gardeners' Chronicle* of the 22d July last, page 503), whose opinion of it is as follows:—

"FASTOLFF RASPBERRY.—We have received from Messrs. YOUELL, of Great Yarmouth, fruit of the Fastolff Raspberry, and we find its merits all that has been stated in favour of its excellence The fruit that we have received is very large, obtusely conical, and of rich flavour, far exceeding in this respect some other new and large varieties. The plants bear abundantly, and in long succession"

They also exhibited it on the 1st of August, 1843, before the London Horticultural Society, 21, Regent-street, to which a prize was awarded. It would therefore be unnecessary for YOUELL and Co. to recommend it more fully, or with greater confidence to the notice of the public, merely observing, that it continues in high perfection throughout the autumnal months, and has maintained its superiority in the most unfavourable soils and situations, and requires no other than the ordinary treatment of the old varieties.

Fine Canes are ready for delivery, and can be sent with safety to any part of the United Kingdom (on the receipt of a Post-office order), upon the following terms:—

	£	s.	d.
Packages containing 100 Canes	2	2s	0d
Do. do. 50 do.	1	5	0
Do. do. 25 do.	0	14	0

Package included.

The usual discount to the Trade where not less than 200 are ordered.

*** CAUTION.—Y. and Co. beg to call the attention of their friends and the Public in general to the fact that they have appointed no Agents in London for the sale of the above, and cannot be held responsible for its being genuine, unless purchased direct from their Nursery

THE NEWEST AND VERY BEST FUCHSIAS, VERBENAS, PETUNIAS, ANAGALLIS, &c., FOR 1844.

YOUELL AND Co. beg to refer the Readers of the *Gardeners' Chronicle* to their Catalogue of the above, which appeared in this Paper of 2d inst., and will be found to contain such varieties only as are worthy of cultivation.

YOUELL & Co being the parties who first sent out per post, with safety, these tribes of plants, are desirous of calling attention to their advantageous method of executing orders, namely, that they will deliver them free of postage (on the receipt of a Post-office order), to any part of the United Kingdom, upon the following terms —

12 Extra Fine varieties, 12*s*, the Selection left to Youell & Co.
12 ditto ditto 24*s*, the Selection left to the Purchaser.
50 Fine varieties. . 40*s*, the Selection left to Youell & Co.
50 Extra Fine ditto . 60*s*, the Selection left to the Purchaser.

VERBENAS.

12 Extra fine Varieties, 6*s*, the selection left to Youell & Co.
12 Ditto ,, 10*s*, the selection left to the purchaser.

With the exception of those marked thus.*

The plants will be strong and healthy, and ready for delivery by the latter end of March, with the exception of those marked thus * (which will be ready in April), thus ensuring the Purchaser fine plants for competition in the ensuing season. Many of the varieties can be supplied now.

CHRYSANTHEMUMS.

50 Newest and Best Varieties, 12*s*. per dozen

PANSIES.

12 Fine Show Varieties, by name, 9*s*. per dozen.
12 Extra fine do. do. 18*s*. ,,

Per post free.

FLOWER-SEEDS.—30 packets of the newest and best kinds, sent per post free for 6*s*

TWO NEW SEEDLING PICOTEES.—"LADY ALICE PERI," 10*s* 6*d*, and "MRS. BUNYON," 10*s*. 6*d*. per pair.—These two splendid Picotees were raised by the Rev. J. Burroughes, of Lingwood Lodge, Norfolk, and kindly presented by that gentleman to Messrs. YOUELL & Co., for particulars of which see their Advertisement in this Paper of the 16th of Sept.

FINEST CARNATIONS AND PICOTEES.

YOUELL AND Co. beg to refer the Readers of the *Gardeners' Chronicle* to their Extensive List, with Prices, of the above highly esteemed Flowers, which appeared on the Advertising pages, 706 and 707, of this Paper, of October the 14th, and will be found to contain every variety worthy of cultivation.

Prices as follows	£.	s.	d.
12 pair of good Show Sorts	1	4	0
12 ditto fine ditto	1	16	0
24 ditto ditto	3	0	0
12 ditto extra fine and very superior ditto	2	10	0
24 ditto ditto	5	0	0

The selection being left to YOUELL & Co.

ARAUCARIA IMBRICATA, recently planted most extensively at Her Majesty's Gardens at Windsor, and also at the Royal Gardens, Claremont, furnished by YOUELL and Co.

YOUELL AND Co., possessing the most extensive stock in the country of the above Splendid Hardy Ornamental Tree, beg to offer them on the following advantageous terms:—fine robust 4-year-old plants, 9 to 12 inches high, 10*s*. per 100; 12 to 18 inches high, 16*s*. per 100; 18 to 30*s*. per dozen.

Fine Plants of CEDRUS DEODARA, 2*ft*. to 3*ft*. 6 ins., 10*s*. 6*d*. each.

Great Yarmouth Nursery, March 14, 1844.

A LIST OF CHOICE FLOWERING PLANTS, SUITABLE FOR SALE OR EXCHANGE, MAY BE HAD OF WARNER AND WARNER, Sabbath Row, No. 28, Cornhill, London.

GARDENERS' GAZETTE	1066

The weekly circulation of the GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE is at the present time (March 20) above 7000, as will be seen by the next Parliamentary Return.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.—SOUTHAMPTON MEETING.—Prize-Sheets and Regulations for the Exhibition of Stock, Implements, &c., together with the blank PRINTED FORMS OF CERTIFICATE required to be filled up by Exhibitors, and copies of the printed Programme of the Meeting, may be had on application, either personally or by letter, addressed to the Secretary, No. 12, Hanover-square, London.

Exhibitors are particularly requested to observe, that all Certificates for Implements, &c., must be sent, complete, so as to reach the Secretary on or before the FIRST OF MAY; and all Certificates for Stock on or before the First of June.

By order of the Council, JAMES HUDSON, Secretary.

London, March, 1844.

SODENS' EARLY OXFORD POTATOES.

HURST AND M'MULLEN, SEEDSMEN, No. 6, Leadenhall Street, London, still continuing to receive numerous orders for the above celebrated Potato, feel it their duty to inform their numerous friends, and the public generally, that the entire Stock is all sold. They have made arrangements, for another season, with Mr. SODEN, to grow a larger supply, and beg to solicit early orders, to prevent disappointment. They have still on hand MARTIN'S new early Globe, new early Wiltshire Kidney, and several other approved varieties. See their Advertisement in this day's Paper.

RANUNCULUSES, ANEMONES, PELARGONIUMS, AURICULAS, CARNATIONS, AND LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by APPOINTMENT FLORIST TO HER MAJESTY, begs to inform the Nobility, Gentry, and Amateurs, that, in consequence of the success he has had in the cultivation of the above flowers at his new Garden, he can offer them at very moderate prices. He would particularly recommend an early application to be made for RANUNCULUSES and ANEMONES, as they should not be planted later than the end of March to ensure a good bloom. His Catalogue of PELARGONIUMS, AURICULAS, and NEW PLANTS, is now ready, and will be forwarded by post on application. The Trade supplied.

FUCHSIA.—MARNOCK'S PRINCESS SOPHIA.—This beautiful FUCHSIA, which was raised by an Amateur, and purchased by Messrs. MARNOCK and MANLEY, is a dazzling vermilion; thick, glossy, substance; large tube, and, excessively brilliant; corolla, dark purplish rose, well expanding and forming a beautiful contrast from the sepals. Plants in April, 10s. 6d. each; an allowance to the trade if three or more plants are taken at a time. Their Catalogue of Fuchsias, Verbenas, Cinerarias, &c., containing every variety worthy of cultivation, with many new varieties of Cinerarias, &c., not yet let out, is now ready, and may be had on application at their Nursery, Hackney.

N.B.—Every description of choice Flower-seeds, at moderate prices.—March 23, 1844.

FINEST CARNATIONS AND PICOTEES.

YOUELL AND Co. beg to refer the Readers of the *Gardeners' Chronicle* to their Extensive List, with Prices, of the above highly esteemed Flowers, which appeared on the Advertising pages, 706 and 707, of this Paper, of October the 14th, and will be found to contain every variety worthy of cultivation.

Prices as follows:

		£.	s.	d.
12 pair of good Show Sorts		1	4	0
12 ditto fine	ditto	1	10	0
25 ditto	ditto	3	0	0
12 ditto extra fine and very superior	ditto	2	10	0
25 ditto	ditto	5	0	0

The selection being left to YOUELL & Co.

ARAUCARIA IMBRICATA.

Recently planted most extensively at Her Majesty's Gardens at Windsor, and also at the Royal Gardens, Claremont, furnished by YOUELL and Co.

YOUELL AND Co., possessing the most extensive stock in the country of the above Splendid Hardy Ornamental Tree, beg to offer them on the following advantageous terms:—Fine robust 4-year-old plants, 8 to 10 inches high, 10*l.* per 100, or 30*s.* per dozen.

Fine Plants of CEDRUS DEODARA, 2ft. to 2ft. 8 ins., 10*s.* 6*d.* each.

Great Yarmouth Nursery, March 21, 1844.

N.B. All Orders above £2 will be delivered carriage free either to London or Hull.

NEW FUCHSIA "ADONIS."

T. PULLEN begs respectfully to call the attention of Nurserymen, Florists, and Amateurs, to the above SEEDLING, which has been pronounced by all who have seen it to be a splendid variety. The flowers are very large, and a very bright colour, with a very waxy substance; is a strong grower, with very fine foliage, and free bloomer, &c. Plants may be had the first week in May, at 5*s.* each, of the Raiser, or of Messrs. HURST and M'MULLEN, Seedsmen, 6, Leadenhall-street, London; who have seen the flowers, and will answer to any inquiries respecting its merits, &c.—Midhurst Nursery.

BUSHELL'S Light Seedling Dahlia, "EMMA."—Plants in May, 10*s.* 6*d.* Colour white, tipped with deep cherry; the petals, form, and centre, good; the largest, most constant, and free in flowering of any Dahlia yet propagated, and has obtained several prizes. "Pet Rival" Plants in May, 5*s.* Colour, purple maroon; fine cupped petal and free bloomer; exhibited in several winning stands last season. Kennington Rose, Plants in May, 5*s.*; most constant Rose grown. To be had of Messrs. ANSELL, Camden Town; S. GIRLING, Stowmarket; F. & A. SMITH, Hackney; and J. BUSHELL, 12, Hall-place, Kennington-lane.

SEEDLING FUCHSIAS.

W. PAWLEY, of the White Hart Hotel, Bromley, Kent, begs to inform the Nobility and Gentry that he has purchased the entire Stock of three splendid Fuchsias, which he intends sending out in April next, at 10*s.* 6*d.* per plant. They are considered by competent and practical men to be the best known, and twice the size of any yet in cultivation.

QUEEN.—A large Flower, a very free bloomer, and of good habits. Colour, a delicate light Pink, and a beautiful Rosy Vermilion Corolla.

PRINCE OF WALES.—A very large bold Flower, and good substance. Colour, a bright Crimson, with an extraordinary large Violet Corolla. Magnet is also a large long Flower, good substance, habit, and a free bloomer.

To prevent disappointment, which is too often the case with new Flowers, the public are requested to come and see them before purchasing. Early orders are solicited, as the stock is limited, having broke very sparingly. A specimen of each will be open to any three Seedlings of 1843, grown from young plants, for the sum of 5*l.* To be exhibited at the West Kent Exhibition, held at Blackheath, in June next. N.B.—If accepted, notice to be given this month.—Bromley, March 22, 1844.

DAHLIAS.—KEYNE'S STANDARD OF PERFECTION, DODD'S ORANGE SUPERB, and DOWDING'S EMMA NOKE.—The Stock of these splendid DAHLIAS is in fine condition, and will be sent out the 1st of May. A List of the Nurserymen who have ordered and can supply Plants, will be advertised the 1st of April. Gentlemen who intend growing these varieties may, by giving early orders, depend on fine Plants the first week in May.—Salisbury, March 5, 1844.

DILLISTONE'S APPLE, the STURMER PIPPIN.—From the satisfaction given last season by the mode of transmitting by post scions of the above most valuable Apple, to distant parts of England, Scotland, and Ireland, S. & J. DILLISTONE are again induced to offer it in packets (true from the original tree), post-free upon receipt of a Post-office order, payable at Halstead, for 3*s.* 6*d.*, or the amount in stamps.

The Editor of the *Gardeners' Chronicle*, in "Notices to Correspondents," NOV. 25, 1843, says—"The Sturmer Pippin deserves the character given of it."

Mr. RIVERS, in the Supplement to his Fruit Catalogue, says—"The Sturmer Pippin again deserves noticing, for its excellent qualities; it seems to grow and bear well in all soils and situations, and will supply the desert or kitchen from March till July. It can be grafted with success till middle of May."

A choice Collection of Roses, Dahlias, Pansies, &c. &c. Nursery Stock in general.—Sturmer Nurseries, March 22, 1844.

PETUNIA PUNCTATA.

W. MILLER refers the readers of the *Gardeners' Chronicle* to his full advertisement of this beautiful flower—just remarking that its *Strong, Dwarf habit*, and *Glossy Dark Green* foliage, (by far surpassing any Petunia yet out), renders it a desirable object for every greenhouse, and especially to all Exhibitors. Strong plants in April, 7*s.* 6*d.*

W. M. can still take orders for his cheap and new Fuchsias and Verbenas, as advertised.

FUCHSIAS.		VERBENAS.	
12 Fine distinct sorts	7*s.* 6*d.*	12 Distinct sorts	2*s.* 6*d.*
12 Extra, very superior	10*s.* 6*d.*	12 Extra, very superior	5*s.* 0*d.*

N.B.—Printed Lists can be had of Pelargoniums, &c.

WILLIAM MILLER, Providence Nursery, Ramsgate, March 19.

SEEDLING FUCHSIAS, PHLOXES, and VERBENAS.

S. GIRLING begs to inform the admirers of the above, that he will have fine healthy plants of his superb Seedlings ready for delivery by the 20th of April. S. G. offers them with the greatest confidence, being well convinced of their superiority over any others he cultivated last year, which included about 100 varieties. The FUCHSIAS have been seen by Dr. LINDLEY, whose opinion on their merits will be found in the *Gardeners' Chronicle*, pages 528 and 561, of 1843, under the signature "*S. Girling.*"

FUCHSIAS.

CANDIDATE.—Deep crimson tube and sepals, petals bright violet-purple, reflexing so as to show the corolla. Price per plant, 5*s.*

GLOBOSA COCCINEA.—Tube nearly globular, dark vermilion, sepals and violet petals. 3*s.* 6*d.*

HERO OF SUFFOLK.—Dr. LINDLEY's description of this is—"No. 5 is a handsome seedling, with short crimson vermilion tube and sepals of good substance, the latter expanding so as almost to reflex, after the manner of Magnifica; stamen and pistils much exserted." Price 7*s* 6*d.*

PHLOXES.

KING OF THE WHITES.—The best white out; height 2 feet. Price 5*s.*

SPECTABILIS.—Shaded lilac, very fine, height 2 feet. 2*s.* 6*d.*

DRUMMONDI, var. SPLENDENS, a new annual of great beauty, being of the richest crimson scarlet, and quite circular in form. In packets of 12 seeds; 2*s.* 6*d.* per packet.

VERBENAS.

DEFIANCE.—Bright rosy pink; the best in its class. 2*s.* 6*d.*

TRESOR PARFAIT.—Bright violet-purple, shaded with deep crimson; quite distinct from any Verbena known. 3*s.* 6*d.*

S. G. also begs to state that his Catalogue of Florist's Flowers is ready, and may be had on prepaid application; it will be found to contain nearly every novelty of the season, any of which S. G. will be happy to receive orders for, and which shall have every care and attention. The Fuchsias and Verbenas will be sent by post, free of charge, where preferred. The Phloxes are now ready for delivery.

Dane Croft Nursery, Stowmarket, March 23, 1844.

WOODLANDS NURSERY, MARESFIELD, near Uckfield, Sussex

WILLIAM WOOD AND SON have much pleasure in acquainting their numerous Patrons and Friends that they have been appointed Agents for the sale of that most invaluable article—WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, samples of which may be seen, and the composition in use, at WOOD and SON'S Nursery. Sold in bottles, with ample directions for use, pints 2*s.* 6*d.*, quarts 4*s.* 6*d.* each. Discount to the Trade.

SEEDLING FUCHSIA, CACTUS, and PANSY, HOLLYHOCK SEED, &c.—LYNCOMBE VALE NURSERY, BATH.

J. KITLEY begs to inform the Nobility, Gentry, and the Public that he has purchased of Mr. POND his unequalled SEEDLING FUCHSIA (PONDII), allowed by all who have seen it to be one of the largest and handsomest Fuchsias of the day; tube and sepals bright crimson, with darker corolla, and extremely free bloomer; fine compact habit; cannot fail to give satisfaction. 5*s.* per plant.

J. K. has a few more plants of fine SEEDLING CACTUS (SPECIOSA SUPERBA), 10*s.* 6*d.* per plant. Also, good healthy plants of his SEEDLING PANSY (LYNCOMBE VALE RIVAL). This Flower, both for shape and decision of colour, is decidedly the best light PANSY out. 3*s.* 6*d.* per plant.

J. K. can recommend his HOLLYHOCK SEED, with the greatest confidence, having taken great care to select from his best full and very double Flowers of 1843 20 distinct varieties, named to colour, which he will *forward to any purchaser* post-free, on the receipt of a *Post-office order for* 5*s.* The whole of the above are now ready to send out.—Bath, March 20, 1844.

SUPERIOR SEEDLING FUCHSIAS, VERBENAS, AND DAHLIA—"HAMPSTEAD RIVAL."

G. SMITH begs to call particular attention to his New Seedlings, which G. S. flatters himself will give satisfaction, as they far surpass anything in their class.

FUCHSIA—"LONDON RIVAL" has been exhibited at Chiswick, and at the Royal Botanic Gardens, Regent's Park; also submitted to the Editor of the *Gardeners' Chronicle*, Aug. 19, 1843, whose opinion of it is as follows:—G. S.'s Fuchsia, London Rival, is a handsome variety, with dark purplish vermilion tube and sepals, the latter opening so as almost to reflex, showing the large crimson purple corolla to great advantage in growth, and free flowering habit of Moneypenil, 7*s.* 6*d.* per plant.

FUCHSIA—CYLINDRIA SUPERBA is described by Mr. Glenny as being the most vivid scarlet that can be conceived, and as having a singularly interesting appearance; it is of strong growth, and a free blooming variety, 5*s.* per plant.

FUCHSIA—GLOBOSA GRANDIFLORA; much larger and superior to Globosa major, 5*s.* per plant.

VERBENA—EXCELSA obtained a first-class prize at the July Show, Royal Botanic Gardens of London, and is a very large compact flower, quite new in colour, being a deep Rose, extra fine, 5*s.*

VERBENA—DELICATA, a fine blush changing to pink, very compact and large, 3*s.* 6*d.* per plant.

VERBENA—ARRAYA, a fine free flowering red with white eye, 2*s.* 6*d.* per plant.

VERBENA—STRIATA, scarlet striped with pink, 2*s.* 6*d.* per plant.

DAHLIA—HAMPSTEAD RIVAL (Cowing's), a Rosy crimson, rising high in the centre, with a great depth of superior formed petals, and is warranted a noble show flower, constant, 4 feet, 10*s.* 6*d.* per plant. Strong plants will be ready by April 20.

London Agents:—Messrs. WARNER, 28, Cornhill; SMITH, Hackney; and the Metropolitan Union.

Country Agents:—Messrs. YOUELL, Great Yarmouth Nursery; STEWART, Salt-hill Nursery; CRIPPS, Tunbridge Wells; and E. TILLEY, Bath.

*** Nurserymen or Florists becoming Agents, their names will appear as received in this Paper.

TOLLINGTON NURSERY, Hornsey Road, Islington.

WOOD'S SUPERB SCARLET PHLOX DRUMMONDII.

J. WOOD begs to announce that, owing to the late unfavourable season, the stock of seed of this beautiful Annual, which gave such universal satisfaction last year, is very small, and that it will in consequence be sold at 2*s.* 6*d.* per packet as last year. Town Agents, HURST and M'MULLEN, 6, Leadenhall-street, Huntingdon Nursery.

N.B. This Advertisement will not be repeated.

GREAT YARMOUTH NURSERY, NORFOLK, 1844.

YOUELL AND CO.,

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN; HIS MAJESTY THE KING OF THE BELGIANS; NURSERYMEN AND FLORISTS BY SPECIAL APPOINTMENT TO HER MAJESTY THE QUEEN DOWAGER.

A SELECT CATALOGUE of the NEWEST and VERY BEST VARIETIES OF FUCHSIAS, VERBENAS, PETUNIAS, CHRYSANTHEMUMS, & ANAGALLIS, offered by YOUELL & CO.

YOUELL & Co., in submitting their Catalogue of FUCHSIAS for 1844, take this opportunity of drawing the attention of admirers of the above elegant tribe of plants, to their select and superb Collection. They have spared no expense in forming a selection of such as are really good, to the exclusion of many that are mere nominal varieties; and they would refer to the numerous testimonials of success which attended their mode of selection last season, collections for Amateurs, for competition at the various Horticultural Exhibitions throughout the kingdom.

YOUELL & Co. being the parties who first sent out per post, with safety, these tribes of plants, are desirous of calling attention to their advantageous method of executing orders, namely, that they will deliver them free of postage (on the receipt of a Post-office order), to any part of the United Kingdom, upon the following terms:—

12 Extra Fine varieties, 12s., the Selection left to Youell & Co.
12 ditto ditto 24s., the Selection left to the Purchaser.
50 Fine varieties . . 48s., the Selection left to Youell & Co.
50 Extra Fine ditto . 96s., the Selection left to the Purchaser.

With the exception of those marked thus, *

The plants will be strong and healthy, and ready for delivery by the latter end of March, with the exception of those marked thus * (which will be ready in April), thus ensuring the Purchaser fine plants for competition in the ensuing season. Many of the varieties can be supplied now.

NEW AND SPLENDID SEEDLING FUCHSIAS.

* "FUCHSIA LINDLEYANA." This brilliant Fuchsia, the entire stock of which is in the possession of YOUELL & Co., is now for the first time offered to the notice of the public.

Its exceedingly large tube and sepals are of the most vivid vermilion, and excessively expansive, surpassing in brilliancy any hybrid that has yet been raised. It was exhibited at the London Horticultural Society's Meeting, Regent-street, and greatly admired, and was pronounced by all who saw YOUELL & Co.'s specimen plant to be the most dazzling object of this tribe they ever witnessed. The foliage and habit exceedingly fine, a most abundant bloomer, and will be found a desideratum to every collection. Plants will be ready for delivery by the first week in April, at 7s. 6d. per plant. Usual discount to the Trade, when not less than six plants are ordered.

YOUELL & Co., in calling the notice of Amateurs and others to the following seedling Fuchsia, raised in their nursery, beg to state that in the summer of 1843 they bestowed every care in hybridising the best varieties in cultivation, from which they succeeded in raising upwards of 3000 plants, to the flowering of which one house was entirely devoted last year. And although many varieties possessing superior claims to the attention of those cultivating this elegant tribe, were submitted for the opinion of Dr. LINDLEY, and most favourably noticed, yet YOUELL & Co. feel that, in making a selection of the following six varieties, to which a most accurate description is affixed, will prove not only satisfactory to the purchaser, but to themselves.

These will be ready for delivery in April next, and as the stock is very limited, early orders are solicited.

* "QUEEN VICTORIA." Tube and sepals smooth, of a bright vermilion, corolla stout, long, of a fine purple rose colour, forming a good contrast, and of fine texture, price 7s. 6d. per plant.

* "PRINCE OF WALES." Tube and sepals rosy vermilion, the latter tipped with green, expanding well, and showing a fine corolla of maroon purple; price 7s. 6d. per plant.

* "PRINCESS ROYAL." Tube and sepals bright red, corolla large and peculiarly bright in colour; price 5s. per plant.

* "MARCHIONESS OF NORMANBY." This is a large and showy flower, measuring four inches from the commencement of the pod to the termination of the pistil, tube and sepals scarlet, corolla stout, having a tinge of purple on it; price 7s. 6d.

* "LADY ALICE PEEL." A flower of good form and substance, fine rosy red tube and sepals, the latter terminating in a decided green, corolla very large and stout, of a beautiful crimson purple; price 5s. per plant.

* "LADY WALSINGHAM." Tube and sepals smooth, of a rosy vermilion, the latter turn up, and expose the whole of the corolla, which is stout, and of a fine purple crimson; price 5s. per plant. When the six are ordered, they will be charged 1l. 11s. 6d. the set.

"FUCHSIA QUEEN." Quite new, very beautiful, and not yet out, tube and sepals large and stout, of pure white, showing a dark crimson corolla; price 10s. 6d. p. plant; ready in April next.

Fuchsia Seed, saved from the best varieties, 6s. to 10s. per packet, with Directions for sowing, &c. &c.

With every other variety worthy of cultivation, that may be advertised by other parties after the publication of this list.

YOUELL & Co. are preparing a short treatise upon their successful mode of cultivation of the Fuchsia, which will be presented Gratis to Purchasers.

VERBENAS.

*"MONARCH" (Youell's) is a delicate creamy white, surpassing in its size and fragrance every other variety; the tufts of bloom measuring from 3½ to 4 inches diameter, and will be sure to give satisfaction. Price 5s. per plant.

* "BRILLIANT," (Youell's). This fine variety is of the most vivid scarlet, equal in this respect to "Melindris;" the bloom, however, is three times the size, and very fragrant, and will prove most desirable in any collection. Price 3s. 6d. per plant.

*"ELEGANS" (Youell's), is a most interesting variety, being a delicate lilac, with a distinct white eye; flower large and fragrant. Price 3s. 6d. per plant.

* "SURPRISE" (Youell's), can be recommended as a variety completely novel, and one that must be cultivated in every collection, the colour being of the richest rosy crimson, or ruby, producing tufts of flowers of 3½ ins. in diameter, and delightfully fragrant. Price 5s. per plant.

The above four varieties have been selected from upwards of 2000 Seedlings, and may be confidently relied upon as possessing superior claims, and will be sure to give satisfaction; will be ready to send out in April next (post-free). If the four varieties are taken, they will be charged 15s. the set.

Do.	do. 25 do.	0	14 0

Package included.

TWO NEW SEEDLING PICOTEES.—"LADY ALICE PEEL," 10s. 6d., and "MRS. BURTON," 10s. 6d. per pair.—These two splendid Picotees were raised by the Rev. J. Burroughes, of Lingwood Lodge, Norfolk, and kindly presented by that gentleman to Messrs. YOUELL & Co., for particulars of which see their Advertisement in this Paper of the 16th of Sept.

SPLENDID LARGE, DEEP-BLUE ANAGALLIS and SUPERB CINERARIAS.—Plants of that large, splendid deep-blue, full and complete round-petalled ANAGALLIS BREWERII, being of a strong and vigorous habit, are well adapted for bedding out; 12s. per dozen.

SUPERB CINERARIA SEED, saved from the most esteemed named kinds, and other new and beautiful Seedlings, comprising every shade of dark and light-blue, at 2s. 6d. per packet. Strong flowering plants of the above, 18s. per dozen. Applications, including Post-office orders, will be immediately executed.—Direct to MICHAEL BARNES, Esq., Cambridge Nursery.

MELON SEEDS.—A very liberal Remuneration will be given for some PERFECTLY PURE AND GENUINE SEEDS of the under-named Melons; or Seeds procured the last year direct from China, Cabul, and Candahar, will be given in exchange:—Striped Honsainee, Daree, Geree, Garmek, Melon of Gerger, Nukshevan, Sweet Melon of Ispahan, and Italian Green-flesh.

Application to Mr. G. MILLS, Gardener, Gunnersbury Park, Acton, Middlesex.

WM. JOHN CORMACK, AGRICULTURAL SEEDSMAN by Appointment to His Royal Highness PRINCE ALBERT, New Cross, Surrey, and Bedford Conservatory, Covent Garden, begs to call the attention of the Nobility, Gentry, and Agriculturists in general to his combinations of GRASS SEEDS for Permanent Pasture, the Alternate Husbandry, Parks, Lawns, &c. (as recommended and practised by his partner, the late Mr. GEORGE SINCLAIR, Author of the "Hortus Gramineus Woburnensis.") Upwards of 25,000 acres have been converted to permanent pasture by this establishment with the greatest success. Parties requiring Seeds are respectfully requested to state the nature of the soils. Mangold Wurtzel, Carrot, and Turnip-seed of excellent sorts, saved from transplanted bulbs. Garden and Agricultural Seeds of the best quality and most approved kinds.

N.B.—Cormack's British Queen and Prince Albert Peas, at 3s. 6d. per quart.

TURNIP SEED, &c., at CHESTER.

FRANCIS AND JAMES DICKSON beg to announce to the Farming community and Agriculturists in general, that having succeeded in saving an unusually large quantity of their "IMPROVED PURPLE-TOPPED SWEDISH TURNIP," (originally from the reputed Ashcroft's Stock, but annually picked and transplanted under their own superintendence), they are enabled to offer it on very low terms.

Also "DICKSON'S PURPLE-TOPPED HYBRID SCOTCH YELLOW," a hardy and much-admired variety. Laing's East Lothian, Pink-topped, Victoria, and other Swedes; White and Cream Globe; Dale's, Gordon's, and several Hybrids; Red, White, and Green Round Turnips, &c. &c.

F. and J. D. have likewise on sale all kinds of FARM SEEDS, in the selection of which they pay particular attention. Mangold Wurtzel, Carrots, Parsnips, Clovers, Imported Scotch Seed Oats, Barley, and Rye-grass. Grasses for Permanent Pasture, &c. &c.

Orders are respectfully solicited, in the fulfilment of which every attention will be paid.—Chester, 20th March, 1844.

LAWN GRASS-SEED.—Mixtures of the finest kinds of GRASSES and CLOVER, warranted to insure a fine Sward (allowing two quarts to the square rod), 14s. per bushel. Sent carriage-paid to London, in not less quantity than half a bushel. Mixtures for Lawns intended to be fed, 10s. per bushel.

JOHN RIVERS, Sawbridgeworth, Herts.

G. CHARLWOOD, 14, Tavistock-row, Covent-garden, begs to inform his numerous Friends and the Public in general, that his Catalogue of AMERICAN SEEDS is now ready for distribution. In it will be found Cones of Pinus Douglasi, 21s. per doz.; likewise, his new General Catalogue, containing all the newest and most improved Vegetable and Flower Seeds; together with an abridgment of the same, containing the more select and rare Sorts.

He has likewise received his annual importation of German Stocks, Asters, Wall-flowers, Carnations, &c., &c. List, with prices, will be found in the Abridgment.

G. C. having been many years in the habit of making mixtures of the different kinds of Grasses for Pasturage of all descriptions, can supply the same from 24s. to 36s per Acre; or, in distinct Sorts, as may be desired. The finer Sorts, mixed for Lawns, at 1s. 6d. per lb. Also Lucerne, 1s. per lb. White Belgium Carrot, 1s. per lb. Altringham Carrot, 1s. per lb. Mangold Wurtzel, 1s. per lb. Yellow and Red Globe Mangold, 1s. per lb. Laing's improved Swedish Turnip, 1s. per lb. Skirving's do., do., do., 1s. per lb. All other Sorts of Agricultural Seeds equally low, and of genuine quality.

AMERICAN FOREST-TREE and SHRUB SEEDS.—A consignment of 24 barrels recently received are offered FOR SALE, either entire or in separate portions, as may suit the convenience of the cultivators of them.—For further particulars apply to GEORGE CHARLWOOD, Seedsman, 14, Tavistock-row, Covent-garden.

The assortment consists of the following articles:—Andromeda, arborea, Mariana, and paniculata; Alnus serrulata, Acer rubrum, montanum, and striatum; Betula populifolia and excelsa; 1 bushel Crataegus pyrifolia, Cornus florida, 2 lbs. Cercis Canadensis, 4 lbs. Ceanothus Americana, 16 lbs. Diospyros Americana, Fraxinus tomentosa, acuminata, and sambucefolia; 14 lbs. Gleditschia triacanthos; Hibiscus syriaca et spec.; 1 bushel Ilex Opaca; 7½ bushels Juniperus Virginiana; 2 bushels Juglans tomentosa; Kalmia angustifolia, latifolia, Laurus Benzoin, Ligustrum Americana; 2 pecks Myrica cerifera; Magnolia glauca, grandiflora, and macrophylla; Prinos verticillatos, Phytolacca decandria, Philadelphus inodorus and grandiflorus; In cones—18 bushels Pinus nigra; 2½ bushels P. balsamea; 2½ bushels P. Canadensis; 7½ bushels P. rigida; 2 bushels P. alba; 3 bushels P. microcarpa; 2½ bushels P. strobus; ½ bushel P. variabilis; 2½ bushels Quercus coccinea; 1 bushel Q. tinctoria; Rhus glabrum Vernix; 1½ bushel Sorbus Americana; 4½ bushels Thuja occidentalis, and several other articles.

G. C. begs to inform his friends and customers that this consignment is totally distinct from his usual supply, of which a priced list may be obtained by application.

PASTURE AND LAWN GRASSES of the Finest Quality, selected for every description of soil, consisting of Poas, Festucas, Cold Grass, Meadow Foxtail, &c., with a moderate supply of Clover, will enable Noblemen and Gentlemen to lay down upon very reasonable terms. Particulars of quantities suitable to various soils to be had, with an estimate of the cost per acre, by application to WARNER and WARNER, Seed-merchants, 28, Cornhill, London. Genuine Italian Rye-Grass, Mangold Wurtzel, and superior selected Turnip-Seeds.

TO FINE GROWERS.

TO BE SOLD BY PRIVATE CONTRACT, between 400 and 500 Fruiting and Succession PINE PLANTS, principally composed of Queen's, Black Jamaicas, White Providences, Black Antiguas, and other good varieties. The whole are in a very healthy, clean condition, and will be found worthy of notice. For Particulars apply to Messrs. JANSON and FINNEY, Gateshead Nursery.

TO GENTLEMEN, FLORISTS AND OTHERS.

MESSRS. PROTHEROE & MORRIS will offer at the Auction Mart, Bartholomew Lane, on Tuesday, March 26th, the remaining Standard and Dwarf ROSES and DAHLIAS; and on Thursday, 28th, a stock of CARNATIONS and PICOTEES, PINKS, NEW FUCHSIAS, HEARTSEASE, &c., the stock of a celebrated Grower; may be viewed the morning of sale. Catalogues may be had at the Mart, and of the Auctioneers, Leytonstone.

"PETUNIA PUNCTATA."

WILLIAM MILLER intends to give a List in next week's *Chronicle* of those Nurserymen that have ordered Plants of this unrivalled Flower. Other Nurserymen who wish their names to be added, must send their orders immediately.

Providence Nursery, Ramsgate, March 21, 1844.

CHOICE PANSIES.

J. HENCHMAN begs to inform cultivators of the PANSY that he is now sending out healthy plants of six good seedling varieties, for 21*s.* the set. Also a few choice kinds at 18*s.* and 12*s.* per dozen.—Edmonton, March 1844.

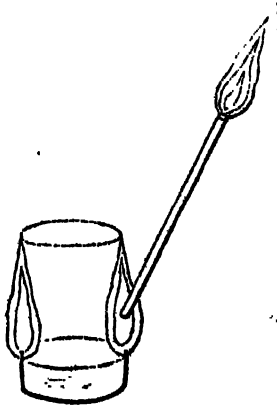
WOODLANDS NURSERY, MARESFIELD, near Uckfield, Sussex.

NEW and SUPERB FUCHSIAS, VERBENAS, PETUNIAS, CINERARIAS, CAMELLIAS, GREENHOUSE and HERBACEOUS PLANTS, HARDY CLIMBERS, and Plants adapted for bedding.

WM. WOOD & SON beg to inform their Friends and Amateurs that a Catalogue of the above, together with a List of entirely new ROSES, is now ready, and may be had GRATIS on application.

The Gardeners' Chronicle.

SATURDAY, MARCH 23, 1844.

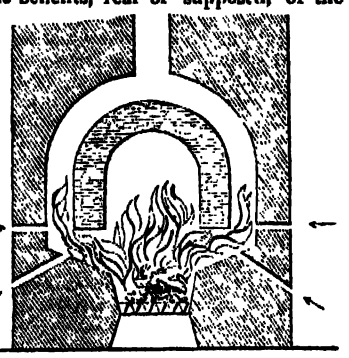


MEETINGS FOR THE TWO FOLLOWING WEEKS.

WEDNESDAY, March 27	Society of Arts	. .	8 P.M.
MONDAY, April 1	Entomological	. .	8 P.M.
TUESDAY, April 2	Horticultural	. .	3 P.M.
	Linnean	. .	8 P.M.

THE well-known experiment of conducting a portion of the unburnt gas from the interior of a candle-flame, and then lighting it at the end of the tube, forms the basis of Mr. Williams's reasonings in behalf of his IMPROVED FURNACE. This experiment, which we recall to mind by the annexed diagram, is assumed as proving that the whole of a gaseous current will never be consumed unless some extraordinary means be previously taken to intermix the gas with the air, whose oxygen is to combine with it. "If, then, the free unrestricted access of air on all sides of this small flame is not able by force, attraction, or the laws of diffusion, to form a due atomic mixture in time for ignition, *à fortiori*, it cannot do so when the supply of air is restricted, and that of the gas increased."

These words form the conclusion of Mr. Williams's notice of the experiment in question, and he proceeds to contrast it with the combustion of an argand lamp (his furnace being called the *Argand* furnace), in which he infers that no such phenomenon could be exhibited. We think, however, that there is a slight error in supposing that because some portion of unburnt gas can thus be abstracted and afterwards inflamed, that it would not have been equally burnt if left to itself. There is little doubt, we apprehend, that the upper part of every flame consists of the gas which but an instant before had formed the yet unconsumed central portion of the volume, and which might have been conducted away and burnt at the end of a tube instead of rising to increase the length of the original flame. We think there is a second error in supposing that in this respect there is any essential difference between the flame of an argand lamp and that of a candle. The combustion in the flame of the argand-lamp is, like that in the candle, successive. The flame has length in proportion to the supply of gas, because each portion of gas requires to be brought to the surface of the flame, in order to gain access to the air; and there is exactly the same central portion of temporarily unburnt gas, throughout the entire ring of the argand flame as there is in the candle, and which may be in the same manner abstracted and burnt at the end of a tube thus.



The great distinction between an argand lamp and a candle consists in the chimney, for without the chimney the best oil in an annular wick burns less perfectly than the commonest tallow with a simpler form of cotton. Besides the draught produced by the chimney, and the consequent increased supply of air, the contraction or shoulder in the chimney drives the ascending current of air forcibly against the rising gas, and compels an intermixture of the air and gas, which is highly favourable to combustion, and which may easily furnish hints for the construction of furnaces.

The effect of this contraction in the chimney, and indeed of any contrivance by which an inflammable gas and the air are made to impinge against each other is very strikingly shown in the recently-invented lamps for burning highly rectified spirits of turpentine. In these, a narrowing of the chimney corresponds with a metal button over the centre of the flame, by means of which the mutual penetration and intermixture of the two currents is made much more complete than in the common Argand lamp, and therefore a material is caused to burn without smoke, which, without some such extraordinary provision, fails to obtain a sufficient supply of oxygen from the air for its complete combustion.

These lamps exemplify very conclusively the leading argument of Mr. Williams, that, in order to obtain chemical combination, it is not sufficient to bring the materials into mere juxtaposition, though they may leave some doubt as to whether the means he proposes are the only ones, or the best for the purpose. The public is much indebted to him for the perseverance with which he has followed out the subject, but we think his own illustration of the Argand lamp scarcely does justice to this invention.

In the annexed diagram we have shown how simply and easily the benefits, real or supposed, of the contrivances in question may be obtained in furnaces resembling those generally used for Horticultural purposes. The apertures in the brick-work marked by 4 arrows, which indicate the course of the entering current of air, are the only novelties, and *they* are new only in this peculiar arrangement, because, as we have already stated, air has been admitted behind the fire for the same purpose for very many years. In this arrangement, the air which enters by the four channels meeting the current of gas at right angles, or rather, indeed, opposed to it, would tend to produce that sort of forced intermixture which is secured in the turpentine-lamps by the peculiarly-formed chimney, and the deflecting button placed above the flame. Common open stoves for dwelling-houses have been made with grated sides and backs to admit air to the upper parts of the fuel, for nearly half a century. For furnaces, the mode of admission has been much varied, though it has never, we believe, been done exactly as proposed by Mr. Williams, nor as is suggested above. Many years since, a furnace was brought before the Society of Arts, and was published in their Transactions, in which the fire-bars are all tubes, through which the air is made to pass, and from which it escapes into a long narrow chamber formed in the *bridge* behind the fire, which communicates with the tubular bars, and from which it issues finally through a thin aperture. This arrangement was supposed to possess the double advantage of heating the current of air, and of cooling, and therefore preserving, the fire-bars. How far all this is accomplished we are not called upon to say; but this proposal, and many others, show that the attention of practical men has been long directed to the supposed necessity of giving air to the gases otherwise than through the fuel.

The first question therefore for any Horticulturist who wishes to avail himself of these advantages, is one having reference to patent rights. The air has been admitted through gratings, through long narrow channels, and through tubular fire-bars, but not through small perforations in bricks, as suggested by Mr. Williams. It may therefore be questionable whether the four or more apertures described in the above diagram, which are supposed to be eight or nine inches long, and an inch wide, could be used without infringing any patent. On this subject we, of course, do not offer an opinion; our business is merely to show with what facility provision may be made for admitting air above the fire in the boilers used by gardeners; because it will be obvious that the arrangement above described is perfectly applicable to conical, cylindrical, and indeed to all the boilers now commonly in demand, as well as to the horseshoe-form shown in the engraving.—*A.*

FUCHSIAS.

(*Continued from p.* 164.)

Having thus stated what the conditions are upon which the just preparation of soils depends, it will be of some interest to consider the separate parts which constitute a correct arrangement of soils in the process of potting. It has been shown by an illustration of § 1, that matter when circumscribed is subject to an undue attraction or cohesion of its parts, and that all arrangements of soil in pots being circumscribed, are, in the absence of some modifying agent, subject to cohesion by atmospheric and mechanical pressure. Suppose, for instance, a flower-pot without the bottom hole which admits the escape of superfluous water, and in that state filled with soil, it is obvious that the application of water, or any other agent which acts mechanically by pressure upon such a mass of confined matter, will naturally tend to lessen the distance between every particle of which the mass is composed, which will thus become, because of the cohesion of its parts, incapable of permitting the uniform action of other agencies (§§ 3, 6, 7.) This shows that the confinement of matter in garden-pots is attended by a loss of the mechanical force by which matter operates. Again, suppose the same amount of soil to be transferred to a pot with the ordinary bottom hole, and water to be similarly applied, it is clear that by the passage of the fluid, and the diminished confinement of the soil, its mechanical force is increased exactly in proportion to the continued agency which acts upon it. We know that the passage of moisture in pots is in proportion to the absence of any obstruction to the bottom hole, in consequence of potsherds over it. This will be clearer, if we consider that, as the gravitating tendency of all matter is to a common centre, and as the theory of gravitation or attraction implies an agent, namely, mechanical force (Herschel), so it is assumed that mechanical agency should be strictly in proportion to the amount of the circumscribed matter it is intended to affect (§ 7.) Admitting the correctness of this view, the reader is reminded that the whole base of an ordinary flower-pot surrounding the bottom hole is diametrically opposed to the natural arrangement of matter which admits the action of other agencies upon it, this defect being in all cases obviated by the internal arrangement of potsherds, which, acting mechanically, modify the pressure of the remaining parts.

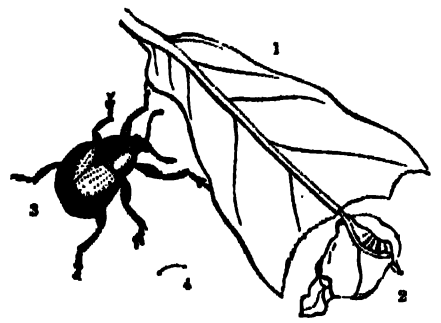
The arrangement of the materials employed in potting may be defined to be—1. Bottom drainage by potsherds, &c., solely intended, according to general cultivation, to act mechanically, by preventing the obstruction of the cavity which regulates the chief drainage. 2. Sub-drainage, by coarse vegetable matter or soil, intended also to act mechanically, by the coarseness of its parts, and nutritively, by its progressive decomposition. 3. Soil, adapted for growth, acting mechanically by its peculiar texture, and nutritively by its uniform proportion of chemical properties.

That these parts should bear a strict relation to each other (mechanically and chemically), has been proved by the principles 7 to 10, inclusive.

In accordance with the opinion given in a previous Paper, which states that the vigour of plants is in proportion to the uniform excitability of their organs,* plants of Fuchsias from cuttings of the current year's growth are preferred to others; and when such are not procurable, the most vigorous, uniform, and short-jointed of one-year-old plants may be selected; and in all cases cuttings from the base or root of the plant are preferable to those from the maturer stem.

On receiving plants which may have been injudiciously potted, with a deficiency or disarrangement of drainage, it is nevertheless better to retain them in their pots (unless injured or broken), in order to regulate the circulation of their fluids, according to the existing state of the plant, as follows:—1st. If the bottom cavity shows, by its close position, that free drainage is impeded, enlarge the cavity externally with an iron wedge, in proportion to its defective state, and thus, without disturbing the vital function of the roots, the first simple remedial process is effected. 2d. If the growth of the plant is feeble, reduce it by pruning to the size which appears most favourable to a uniform and accumulated vigour. As the future figure of the plant is regulated by its first formation, the following rule may be given for plants of one year's growth, namely, a branch may be formed from every axil or bud, where already the small young leaves appear; but, where they are wholly absent, there is a risk of a very late development: this, however, will depend in some measure upon the uniform excitability of the plants, and upon the nature of the atmosphere to which they are exposed. 3d. Open the surface of the soil; and, 4th. Raise the pots either upon a shelf, or on inverted pots on an ordinary front platform of a stove or forcing-house, where the heat is maintained at from 55° to 70°, where they will require occasional waterings, with alternate syringings. The importance of syringing is in proportion to their continued exposure to strong sun-light, and an otherwise dry atmosphere; apart from other reasons, which will be hereafter noticed. In this position they remain until the buds are formed as young branches, and the roots are making their appearance at the enlarged cavity.—*William Wood, Pine-apple Place.*

(*To be continued.*)



ENTOMOLOGY.

ATTELABUS CURCULIONOIDES (*the Black-legged Coral Weevil.*)—There is no district, however barren, nor any period of the year, however cold and dreary, that will not afford amusement and instruction to the reflecting mind, if imbued with a taste for Entomology and other branches of Natural History. Even in the Polar regions our enterprising countrymen found various insects to capture and admire, and tropical countries are swarming with species which vie with the splendid feathered race in the brilliant lustre of their plumage. We need not, however, wander from our native land for amusement, if we are disposed to study the economy of insects; there is not a wood, field, or meadow, heath, or hedgerow, that will not present abundance of materials to those who seek diligently and zealously to explore the treasures that Nature has in store for those who become her admirers, and we are often rewarded in the pursuit when we least expect it. I remember rambling in a wood early in June, admiring the charming wild flowers which there adorn

* *Chronicle*, p. 733 (1843.)

every uncultivated spot, enlivened by the cheerful hum of busy flies, which hover over every sparkling leaf, when I was attracted by the singular aspect of the foliage of a sapling Oak, the basal half of the leaves alone appearing to be alive (fig. 1), whilst at the extremity was suspended a little sort of pod (fig. 2). On examining them attentively, I found each leaf cut through to the midrib on either side; the apical portion had been folded together, so that the two upper surfaces were applied to each other, an egg having been previously deposited near the apex, and the whole had then been rolled up, beginning at the extremity, by which process the broadest points of the leaves were often left sticking out. This operation being performed when the leaf has become soft and flaccid, from the division of the vessels, it rolls up firmly, and as it dries it becomes brown, hard, and very difficult to unrol, unless it be relaxed by moisture; and to expedite the extinction of vitality in this portion of the leaf, the animal eats a deep little hole in the midrib, about an eighth of an inch from the cut margin, so as to interrupt entirely the supply of sap beyond the point of the basal portion, which remains alive and adheres, of course, to the branch or twig of the tree.

Having collected about a dozen leaves thus transformed into the *nidus* of an *insect*, I soon returned home to commence unrolling one, and found within a quarter of an inch of the apex an egg, about the size of a small pin's head, smooth, translucent, yellow, and shining; it was nearly globular, and apparently loose, for it rolled off immediately, and in this instance I had employed no moisture in the unrolling which could relax the gum, by which eggs are generally attached. The leaves had, no doubt, been recently rolled up, for upon some of them I saw the Coral-red Weevils, which were very conspicuous, contrasted with the rich green foliage on which they were resting, and relieved by their jet-black legs. As this is nearly allied to a similar insect which I have bred from the Hazel, it will be advisable to describe the species before us, which Linnæus named

Attelabus curculionoides (fig. 3).—It is intensely black and shining; the thorax and elytra are bright red; the head is oval, with a small but prominent eye on each side; the nose is elongated, and forms a short punctate rostrum, a little dilated at the extremity, which is furnished with two mandibles, minute palpi, &c.; towards the base of this rostrum is a little tubercle, on each side of which are inserted the antennæ; they are longer than the head, straight, and 11-jointed, the two basal joints being a little shorter than the six following, the three apical ones forming a slender elongated club; the thorax is semi-ovate, and minutely punctured; the elytra are nearly twice as broad, very short, and rounded at the apex, indistinctly punctured, with nine punctured *striæ* on each, the sutural one short; the legs are long, the anterior appearing the longest; the thighs are stout, the tibiæ slender, a little curved, serrated, and bristly internally, with two small claws at the apex; tarsi longish and 4-jointed, two basal joints obtrigonate; 1st, the longest; 3d, bilobed and cushioned beneath; 4th, slender, clavate, furnished with two small but strong claws.*

Having seen many other sorts of trees similarly affected, I shall return to this subject as soon as I have ascertained the various species which are the authors of the work; and I doubt not they belong to the genera Rhynchites, Deporaus, and Apoderus.† The present species, however, will supply abundant employment to any one who has leisure to study its economy—for I saw nothing of the operation—which would be highly interesting. The mouth, as above stated, is at the extremity of the rostrum, and being furnished with jaws, it, no doubt, first cuts the leaf transversely, and afterwards the egg is deposited; from this we may infer, that the female is the skilful operator; but may not the male assist her in rolling up the leaf? which, it must be admitted, is a very curious piece of workmanship for so small an animal to execute. The natural size is exhibited by the curved line at fig. 4. The maggot of another species I have found in its leafy case, and although I have not discovered the pupa inclosed, it is certain that the transformation takes place where the larva is nourished, from my having witnessed the fresh-born Attelabus emerging from its cartridge-like cell.—*Ruricola.*

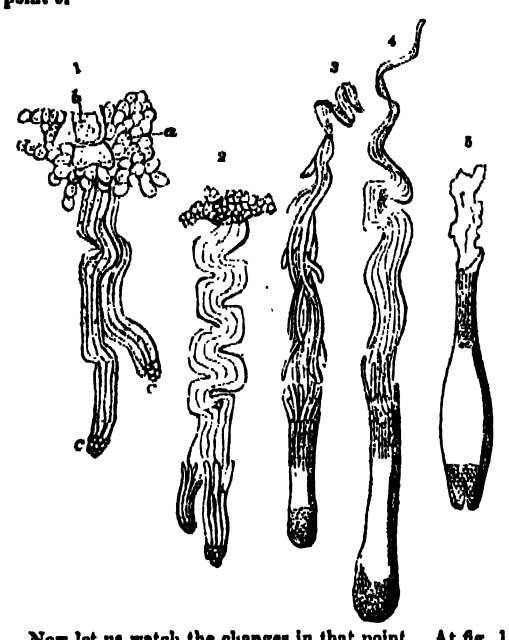
FAMILIAR BOTANY.

MORPHOLOGY, No. VIII.



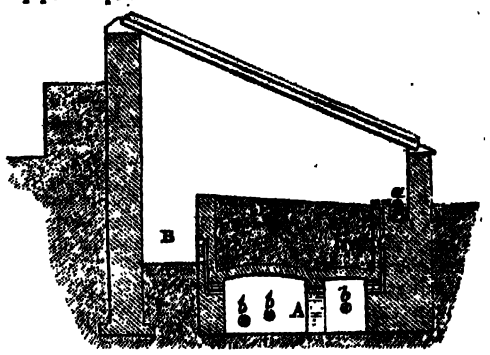
(*Continued from page* 168.)

"Ohne studium der Entwickelungsgeschichte giebt es keine Wissenschaft der Botanik."—SCHLEIDEN.

OUR first two steps have carried us over the threshold of Morphology, and have shown that in the first place all the kinds of matter known in the vegetable kingdom are little transformations of an extremely small number of physical elements; and in the second, that every herb, grass, or tree, is built up with one organic element only, differently fashioned by plastic force. As hydrogen, oxygen, and carbon are the foundation of all the tissue of vegetation, so is the cell, first-born and simple, the parent of every other, even the most apparently complicated and dissimilar form of that tissue; so that the succulency of plants, the toughness of timber, and the elastic springs that lie hidden within the veins of the leaf are all derived from one common state, through various transformations.

How wonderful and admirable is this simplicity! how much more consistent with our finite notions of the power and wisdom of God, than to suppose that a hundred different things are to be made in the first instance, and then put together after the fashion of man! How beautifully, let us add, is this marvellous plan adapted to the nature of the bodies in which it is worked out, and how inconceivable is it, by any one really acquainted with the true nature of created beings, that any other plan should have been adopted, or in fact that they could be fashioned in any other way.

Let us now direct our attention to the manner in which the tissue (or organic elements as distinguished from the chemical or physical) are themselves brought together when a plant is to be generated. The way in which the common Yew forms its embryo within the young seed may be taken as a beautiful example. (See a curious paper by Mirbel and Spach, in the Annales des Sciences for Nov. 1843). In this plant, as in all others, the young seed is in its earliest condition a mere bag of mucilage, containing rudiments of cells which gradually arrange themselves in a regular and somewhat honeycombed manner. After a time the interior is acted upon by the point of a pollen-tube, which is itself a cell drawn out into a long and even microscopically minute thread. Then begins an active change among the cells; from *a* and *b*, fig. 1, which are primitive cells of different kinds, extend others in the form of tubes, which pass irregularly into the cavity of the young seed, and there ceasing to lengthen, the next formed cells reassume their first condition, as at *c*. We must pay particular attention to the point *c*; the tubes themselves are but *suspenders* of that point, and undergo no very important change after they have once acquired their natural length; they become more numerous, and more solid, as at fig. 2; or they separate as at fig. 3 and 4, or they gradually become absorbed and disappear, as at fig. 5; all these alterations being consequent upon their growing older, and ceasing to be of use to the point *c*.



Now let us watch the changes in that point. At fig. 1 it is a little heap of cells; at fig. 2, it is older, and has become rather larger, but still is not materially altered; at fig. 3, it is becoming far more compact, and has assumed the appearance of a short cylinder of cells (part only of which are shown in this and the following sketches); at fig. 4, it has become some weeks older, is still larger, begins to separate from its suspender; and at fig. 5, when nearly perfect, it divides into two lobes and contracts at its base, possessing scarcely any connexion with the suspender, which has become useless, because the original point *c*, to nourish which the suspender was wanted, has advanced from a few cells, with scarcely a fixed form, through various intermediate changes, to the condition of an independent embryo plant, with two lobes or cotyledons which are rudimentary leaves, and a solid mass which represents the future stem and root. It is still, however, merely composed of cells, and in that respect has scarcely changed from what it was at the first hour of its birth.

Here we have a young plant in its embryo state indeed, but perfectly organised, formed by the gradual addition of cell upon cell, till it has gained its destined form. And out of these simple materials all the future fabric of the Yew-tree is to be produced.—*R. E.*

PLAN OF PINE AND MELON PITS AT WORSLEY GARDENS.

THE objects I wished to accomplish in erecting these were—1st. A circulation of air without loss of heat; 2d. A supply of moisture at command, proportionable to the temperature; 3d. A desirable amount of bottom-heat; and 4th, A supply of external air (when necessary) without producing a cold draft.

The method by which the first of these is accomplished will be understood by referring to the section in which *a* is the flow-pipe, *b b b* the return-pipes in the chamber A. It is evident that, as the air in the chamber becomes heated, it will escape upwards by the opening *c*, and the cold air from the passage (B) will rush in to supply its place; but the ascending current of heated air coming in contact with the glass is cooled, descends, and, entering the passage (B), passes into the chamber (A), where it is again heated; and thus a constant circulation is produced. In order to obtain the second object, I have to some extent combined the tank and pipe systems. The flow-pipe *a* is placed about half its diameter into the channel (C), which, when filled with water (or so far as is necessary) gives off a vapour exactly proportionable to the heat of the pipe and pit.

The third requisition is produced by the surrounding atmosphere and heating materials. The fourth is accomplished simply by lowering the upper sash; the cold air thus entering at the top only, falls directly into the passage (B), and passes through the hot chamber before coming in contact with the plants. In order to test the circulation, I fixed a piece of paper near the front of the pit, and found the current to be so strong as to bend it backwards and give it a tremulous motion. When the heat in the chamber is 95°, in the open space over the bed it is 71°, in the bottom of the passage only 60°, and in the mould in the bed it is 80°. The amount of vapour is regulated with the greatest facility, even from the smallest quantity to the greatest density. In one division of the Melon-pits, at present employed as a propagating house, the cuttings have for some time past been covered with a fine dew, and yet not one of them has been injured by damp. This I can only account for by the air around them being kept in constant motion.—*John Mitchell.*

Home Correspondence.

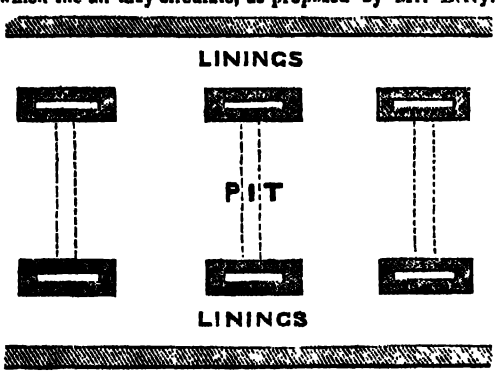
Functional Disease.—In the 10th Number of the *Gardeners' Chronicle* the possible existence of functional disease, apart from structural derangement, in organised bodies, is maintained by a correspondent, who, in support of his position, compares the working of an animate organ to the operations of an inanimate engine, and asserts that because a want of due adaptation of the moving power of the latter to the work to be done is simply a functional derangement, therefore a deficient supply of moving power, whether derivable from nerves or blood-vessels, to the animate organ, causes also a purely functional disease. Does not a very small amount of consideration make it evident that this illustration is peculiarly unapt to the purpose for which it is professed that it is designed, and far more likely to mislead than to enlighten those readers who do not chance to be very well acquainted with the physiological and pathological workings of their animal machines? It appears to us that the cause of movement in all inorganic machines (for such we presume your correspondent to mean when he writes of inanimate), is simply and solely mechanical force, the operation of the physical properties of matter, whether elasticity or friction, or gravitation, upon matter endowed only with the like physical properties, although moulded into some peculiar form; in this case function springs out of rest. It would be of little use that the particles of steam were endowed with elasticity and expansibility, if the piston-plate had not also impenetrability and the moving parts inertia; and those very properties especially indispose the material of the engine to take upon itself structural change; so that its "diseases" and "derangements" must be solely from some mal-application of the moving power. But surely this is not the condition present in any animate "machine:" the moving cause there is continued change. The vital blood and nervous influence do not come to the animal organ as the steam to the high-pressure cylinder, or the moving stream to the wheel. They furnish to the living organism the material by which structural changes are immediately impressed upon its constitution—changes upon which its very existence as a portion of vital organisation hangs. The perfection of its intimate constitution requires the continued operation of waste and repair; and consequently, if what your correspondent calls the supply of the moving power—that is, blood and nervous influence—be withheld, the immediate consequence is the presence of structural disease. That there shall be no structural derangement it is required that that structure shall be continually and constantly renewed—that the affinities of the corroding oxygen conveyed by the blood shall seize upon the products of incipient decay, and remove them from the vital tissues, where their continued presence must be injurious. The happy father of a family who eats a hearty dinner, and hears of his collegiate son's death immediately,

that he may prove your correspondent's position, seems to us to have had his fit of dyspepsia rather unopportunely for that purpose; for surely it cannot be true that in his loaded organ of digestion there is "functional derangement without change of structure." The coats of his stomach are thrown into a state of great vascular activity, under the application of the stimulus of the imbibed food. That there shall not be structural derangement in the organ, it is required that a certain series of changes shall ensue; that a portion of the organ already in an incipient state of decomposition shall be mixed up with the loosened atoms of ingested material, to cause in them an analogous chemical change. But it so happens that by a sudden impression upon other organs of the animate individual, the series of changes constituting healthy action is checked; the organ becomes consequently structurally deranged; and the result is, that impairment of function becomes the evident indication of the concealed cause of the evil. In the inorganic engine of the mechanist, fixity of material is necessary to the perfection of the machine, so that when the active stimulus is withheld from it, no alteration in structure ensues, although it ceases from its work; while in the animal and vegetable organisation, loose chemical affinities and aptitude for continued change are the conditions required in order that it may do its work effectually; and when the needed stimulus is withheld from it, the necessary and unavoidable derangement of intimate structure is the immediate cause of functional disease; and that derangement may be either so subtle in its nature or slight in its degree, as to be only discovered by the disordered function which it has caused; or it may be so evident, as to be at once detected and known. And in this difference of degree, and this only, we presume, is to be found the source of the useful but inaccurate and unphilosophical division of the pathologist of structural and functional diseases. Your correspondent conceives that he disposes of sundry objections to his position, when he admits the agency of the blood as a motive power in animal organs. It is surely more important that he overlooks the fact, that it becomes a motive power only by inducing structural change. We are not quite able to see, being ourselves perchance but little skilled in the philosophy of harmony, the weight and bearing of the abuse of the poor musical instrument to the question at issue; but we yet have enough of practical harmony within us to hold the hand of good fellowship to "M. D." while thus differing from him in our views. And we offer to bet him, in good honest English mood, our earliest Rhubarb plant against his best Melon, that the next time he undertakes, in the routine of practice, to remove a functional disease, he will seek, notwithstanding his avowed theory, to call to his aid some remedy that will apply its energies to the structure of the deranged organ, either by mediate or immediate means; and, wishing him all the success practically, which theoretically we deem he does not deserve, we beg to remain—*Der Greif.*

Durability of Timber.—Your correspondent "P. P." in the *Chronicle*, p. 150, will find the following passage in Davy's Third Lecture on Agricultural Chemistry, at p. 139 of the 6th Edition, 1839:—"The woods that contain aromatic oils are remarkable for their indestructibility, and for their exemption from the attacks of insects; this is particularly the case with the Cedar, Rosewood, and Cypress. The gates of Constantinople, which were made of this last wood, stood entire from the time of Constantine, their founder, to that of Pope Eugene IV., a period of 1100 years."—*C. J. Lancaster.*

Aviaries.—In reply to "M. E.'s" inquiries relative to the description of birds suitable for an Aviary 17 feet by 12, I beg leave to state that I have kept birds for several years, in an Aviary 28 feet long, 9 feet wide, and 12 feet high, divided, however, into two parts, for the following reasons:—I found that the class of birds named Sylviadæ, or soft-billed, were not destructive to flowers, trees, or plants, beyond occasionally soiling them, which is easily remedied by frequent ablutions, and that their food differed from the other class Fringillidæ, &c., or hard-billed, which are destructive to every living plant, and for which dry twigs on a leafless tree served as perches. I will enumerate those I have been in the habit of keeping together in each separate division.

Sylviadæ.	Redbreast	Fieldfare
Nightingale	Long-tailed Tit.	Redwing
Black Cap		Song Thrush
Garden Warbler	Fringillidæ.†	Blackbird
Hedge Sparrow	Chaffinch	Starling
Comm. Whitethroat	Goldfinch	Large spotted Woodpecker
Lesser Whitethroat	Greenfinch	Green Woodpecker
Redstart	House Sparrow	Nuthatch
Stonechat	Tree Sparrow	Jay
Whinchat	Bullfinch	Lapwing
Wheatear	Linnet	Barbary Dove
Pied Wagtail	Averdevine	Turtle Dove
Grey Wagtail	Redpole	Wood Pigeon
Yellow Wagtail	Hawfinch	Blue Tit
Willow Wren	Bramblefinch	Cole Tit
Hedge Warbler	Canaries	Marsh Tit
Woodlark	Twite	Water Hen
Titlark	Crossbill	Partridges
Skylark	Blk.-headed Bunting	Pheasants
Meadow Pipit	Common Bunting	Quails
Snipe	Yellow Bunting	Water Rails, and
Common Wren	Cirl Bunting	Kingfishers.
Spotted Flycatcher	Missel Thrush	



Should "M. E." wish further information, I shall be happy to communicate with him, by his addressing me to that effect.—*W. Rayner, Surgeon, Uxbridge.*——Another correspondent writes thus "you may put into your aviary 5 cock and about 12 hen canaries—the cocks rich, and the hens mealy. You may add two or three goldfinches, linnets, yellowhammers, chaffinches, or siskins;* but these should be all cocks, in which case you may have some mules. Feed daily on the best canary and rape-

* Hedge-sparrow, reed-sparrow, and greenfinch.

seed, three parts to one. Give fresh groundsel, as seedy as you can get it. Boil an egg hard, and cut it in two. Bread is quite unnecessary, even when you have young birds. Fresh clean water in a flower-pan, about seven inches over, every day. Your seed may conveniently be put into a tin receptacle, called "a witch." No growing shrubs or plants can be kept in the aviary; but thick boughs may be fixed up, either with or without boxes or baskets, for the nests. To enable them to construct these, you cannot supply them with anything better than fine sweet hay. If the aviary is open to the sun, you will be much better without any additional source of heat. I have now canaries building in an open aviary. You may add skylarks, and the song-thrush; not the blackbird; but in this case you must give hemp-seed and bread-crumbs. You may, instead of the seed-birds, put in soft-billed birds, such as the nightingale, blackcap, whitethroat, &c.; but the two sorts seldom do well together, and the latter are much the most precarious and troublesome. These observations are the results of some years' experience.—*Corylus.*

Mr. Loudon.—A paragraph having appeared in several of the newspapers, stating that above a thousand pounds had been subscribed for poor Mr. Loudon's books, since his much lamented death, many of our friends have supposed that Mr. Loudon's family are now free from all pecuniary difficulties. This, however, is far from being the case; for though it is quite true that the large sum alluded to has been collected (and the greater part of it in the short space of six weeks, since the first advertisement on our behalf appeared in the *Gardeners' Chronicle*), yet more than half the original debt is still owing, and till the whole of it is paid, Mr. Loudon's family cannot derive the slightest benefit from his copyrights. I am anxious that this should be known, in order that our friends may be aware of the important service they will still do us by ordering copies of poor Mr. Loudon's "Arboretum," or any of the other works which were his own property; and I cannot conclude without expressing my warmest gratitude for the kindness we have already experienced. It is, indeed, only when we are in trouble, that we find how much real goodness there is in the world.—*J. W. Loudon, Bayswater.* [We understand that his Royal Highness the Duke of Cambridge has kindly expressed his intentions to become a purchaser of the "Arboretum Britannicum," and that a meeting in behalf of Mrs. Loudon has lately been held in Edinburgh, which promises to be attended with successful results.]

The Heckfield Melon-pit.—In this pit, as described and alluded to in former Nos. of this Paper (p. 892, 1843, and p. 54, 1844,) the front and back walls have been considered as unbroken, and, therefore, as cutting off all direct communication between the linings and the interior of the pit. The effect of the linings was limited, therefore, to heating the cavities in the front and back walls, through which the circulating air was made to pass, and no means of access to the litter within the pit existed, except through the bed on which the plants were growing. It has been thought, therefore, that all the benefits of the original contrivance might be retained, and the inconveniences in question be removed by building the front and back supports as detached hollow piers, having communicating drains at bottom, as shown by the dotted lines, through which the air may circulate, as proposed by Mr. Berry.

The plan is fully explained in the annexed figure, and it will doubtless be considered as an improvement on the former arrangement.—*A.*

Joints of Hot-water Pipes.—In our last Number, we recommended the use of old rope-yarn for making these joints. We are since informed that when the rope has been much saturated with tar, this material melts out with the heat, and sometimes leaves the joints imperfect. It is, nevertheless, very much employed; but new or at least untarred yarn is better, where the permanence of the joints is greatly desired.

Wash for Fruit-trees.—You constantly recommend that Fruit-trees should be done over with lime as a wash. Nothing can look more frightful than their glaring conspicuous trunks on a hot summer's day; and to obviate this dissight I use cow-dung, soot, or wood-ashes, mixed up with urine, the drainage of a dung-mix, or ammonical water from the gas-works, to the consistency of thin paint. This composition appears to me to possess all the advantages of the lime, and the trunks of the trees appear less-cased, and altogether much more pleasing to the eye.—*J. C. S.*

Bees.—In answer to a "Constant Reader," I beg to state that the period of the year when artificial swarming is resorted to, is from the beginning of May to the middle of July, or as soon as the stock-hives are full of Bees. In order to ascertain when hives are ready, it is necessary to blow a little smoke into them, then lift them up and look how many Bees are on the boards. If there should be as many as will fill a 32 or 24-sized flower-pot on each board, it is time to take off swarms. In 99 cases out of 100 the queens run up into the empty hives, but it is advisable to ascertain that they are with the swarms before they are put into the hives, which are prepared with sticks and combs to receive them. The swarms would be drummed into these hives at once, if the sticks and combs did not make it more difficult to see the queens. When swarms are drummed into empty hives the queens are easily seen, for the Bees fall to the crowns of the hives, when they are inverted, and then run up the sides. If the queens are not seen within the space of two minutes from the time the hives were inverted, the Bees must be put on the crowns of the hives with spoons. If it happen that a queen has not left the stock-hive, drum her and a few Bees into the sticked-hive, and throw the swarm in beside them. On the 17th or 18th day afterwards, second swarms will issue from the stock-hives, and on the 21st day all the brood, but a few drones, being 24 days in their cells, will be hatched, on the evening of which day all the Bees are drummed into empty hives. Thus we obtain three swarms and a pound's worth of honey at an early season, from every stock-hive. If a pound's worth of honey cannot be thus obtained, it is better not to drum the swarms out. Instead of taking the honey out of these hives after the Bees are drummed out of them, it is often more profitable to put them in a garret till September, when two swarms ought to be put into each. The honey is simply squeezed or allowed to drop out of the comb.—*A. Pettigrew.*

Grafting.—As this is the proper time for grafting, I beg to subjoin a list of plants the most difficult to take, but which will invariably succeed, if, in addition to clay-ing, they are moulded up to within a bud of the scion; to admit of which, the stock must be cut very low, as near the ground as possible, the earth drawn up in a pyramidal form round the plant:—

Willows.	Mistletoe on Apples.	Laburnums.
Ligustrums.	Cotoneaster on Thorns, &c.	Ash.
Euonymus.		Vines.
Chinese Cherries.	Roses.	Azaleas.
Pinuses.	Acacias.	Rhododendrons.
Daphnes.	Elms.	Andromedas.
Evergreen Oaks.	Poplars.	Kalmias.
Loniceras.	Chesnuts.	Lilacs.
Jasminums.	Limes.	Deutzias.
Pears on Quinces.	Almonds.	Arbutus.
Pears on Thorns.	Cytisus.	Phillyreas.
Laurel on Cherries.	Sorbus.	Careganas and
Mespilus canadensis.	Currants.	Ribes.
Pyrus spectabilis.	Hollies.	

—*Union.*

Solandra grandiflora.—Among the many plants that adorn the conservatory with blossoms at this season, few are more showy than is Solandra grandiflora; and as this plant in many places does not bloom freely, I shall give my method of flowering it: After it attains to the height of from 3 to 5 feet, I do not shift it, but it is allowed to remain in as small a pot as it will grow in until the roots become matted round the outside of the ball; this, in some measure checking over-luxuriance, without injuring much the constitutional vigour of the plant, gives it a disposition to bloom. Early in autumn it is kept in a cool situation, and allowed to become perfectly dry, when the leaves will drop off. About the beginning of November it is introduced into heat, and forced gently, supplying it plentifully with water when it begins to grow. Being thus excited for a short time, the plant grows freely and produces blossom-buds on the young wood, and at the end of each shoot, these in January and February, expanding into large Magnolia-like flowers, have a gay and imposing effect. As soon as it has done flowering, which is generally in March, the shoots are cut back, and the plant, being shifted, is put into heat, and encouraged to grow, stopping the young shoots frequently, to induce it to throw out laterals, and to keep it dwarf. By this treatment it very often forms spurs similar to a Pear or Apple-tree, at the ends of which, after allowing the roots to become matted in the pot, giving it a rest, and keeping it dry and cool from August till November, blossoms are produced in abundance upon its being put again into heat, and excited into growth.—*J. Brown, Whittlebury Lodge Garden, Towcester.*

Hops.—Will any scientific reader be kind enough to inform me whether the Hops are a necessary ingredient either for yeast or for making beer keep? Or are they merely useful for flavouring? Have they really, when thus applied, any antiseptic virtue? If they have, why will not a strong decoction keep for any length of time in a Chemist's shop? If they are of any use in keeping beer, it must be in checking the tendency to fermentation; and if so, would they not be better left out in making yeast?—*J. B. K. L.*

Miscellaneous.—*Nova* states that Heath has been long used for edgings in the gardens of the Lord Great Chamberlain, where it is much admired during summer and autumn. In 1840 and 1841 about 1000 yards were laid, and most of the old edging was renewed, the soil was taken out eight inches wide and eight inches deep, and the trench filled up with bog-earth. Into this the heath was planted firmly four inches broad; it is cut square every spring. Planted and managed in this way it will stand for 10 years without being renewed, and if it is cut twice in the year it will stand longer. It should be planted in spring.——*A Correspondent* states that he has tried Humphreys's compound with success on several Hyacinths this year, and also on several sorts that would not hitherto root in water. This season they have rooted very freely and strongly; the whole of the blossoms are considerably larger and more beautiful; the foliage is dwarf and waxy. ——*Wax* inquires if any of our correspondents can inform him where he can purchase or see one of "Wildman's mahogany hives."——*M. P. E.* suggests that

the culture of Tropæolum tricolorum might be attempted in the open air with success, as it is grown in abundance in the cold climate of Cashmere, where it forms an important article of food, as related by Baron Von Hugel in his Travels.——*J. Webster* observes, that for Orchidaceous plants, where fibrous peat is scarce, an excellent substitute is to be found in woods, where leaves, sticks, &c., have accumulated and become a mass of fibrous roots. This material is lifted with a spade, about the thickness and in the same way that turf is lifted, and is again cut into smaller pieces when it is used.——*R. S. D.* informs us that being obliged to form a cut through an old meadow which had been drained some 13 years ago with spray or brushings of Spruce and Scotch Firs, he found the drains were running well. He states, that to his astonishment, soon after exposure to the air the Firs budded freely.

Societies.

HORTICULTURAL SOCIETY.

SIR C. LEMON, Bart., M.P., in the chair. Mr. Wm. Cock, Jun., was elected a Fellow of the Society. Mr. Cockburn, gardener to the Earl of Mansfield, at Kenwood, sent bulbs of Oxalis Deppei for the purpose of being distributed. A smaller, and in every respect an inferior kind to this, is generally cultivated for it, which is no doubt one reason why this root is not more in use for culinary purposes. In Belgium it is extensively grown, where not only the tubers but the leaves are also made use of. Respecting its culture Mr. Cockburn says, "I have grown it for several years, and I am convinced that if a little attention is paid to its cultivation it will be found very useful in the months of October, November, and December; but it would require a longer season of fine weather than our climate affords to bring its tubers to perfect maturity. The bulbs should be potted as early in spring as circumstances will permit, and as they vegetate in a low temperature the pots may be placed in a Peachhouse, greenhouse, or even in a cold frame: but they must not be turned out of doors until all danger of frost is over. They thrive best in a light sandy soil in a southern exposure; the bulbs may be planted from 9 to 12 inches apart each way, and should be so arranged that they may be protected from the early frosts of October and November by a slight covering of straw, mats, or spare lights. As 8 or 10 good tubers are sufficient for a dish, there may be 2 or 3 dishes a week for 3 or 4 months, which is no small acquisition to a gardener who has a family at that season to supply with vegetables. Along with these Mr. Cockburn sent for exhibition a tall well-grown specimen of Correa Harrisii, for which a certificate was awarded.—From Mr. Robertson, gardener to Mrs. Lawrence, was a collection of plants, containing handsome specimens of Epidendrum rhizophorum, a rather scarce plant, remarkable for its bright orange-red blossoms; Illicium religiosum, a hardy greenhouse plant with pale green flowers, and somewhat resembling a Spurge Laurel in appearance; Dendrobium secundum, with handsome small racemes of purple flowers; a tall plant of the old Cyrtopodium Andersonii, in excellent condition; also Batemannia Colleyi, Schomburgkia violacea, a good specimen of Cyrtochilum maculatum remarkable for its fragrance, an Amaryllis and 5 pretty plants of Epacris, viz. E. impressa, variabilis, nivalis, attenuata rubra, and a variety of impressa. A Knightian medal was awarded for the first 4 plants.—Mr. Graves, gardener to Mrs. Cannon, sent a bloom of an Epiphyllum from Brazil, which was not different from E. violaceum.—From C. B. Warner, Esq., was Camarotis purpurea, an East Indian species, having gracefully drooping racemes of purple blossoms, and a large flowered variety of Lycaste Skinneri that was imported late last autumn; the bulbs were at first placed in an Orange-house, and were not exposed to the sun until after roots were formed. The plant was then removed to the cool Orchidaceous-house, where it has since been growing—a certificate was awarded for the former.—Mr. Plant, gardener to J. H. Schroder, Esq., sent Vanda cristata, singular on account of the curious form of its flowers; and Oncidium bicornutum having a fine spike of dingy yellow blossoms: a certificate was awarded for the Vanda cristata.—From Mr. Jackson, of Kingston, was a large specimen of Erica Cushiniana with small purple blossoms; and Morina longiflora, a scarce herbaceous plant, which will grow out of doors, but does better to be kept in a cool frame or in a greenhouse, where, if it is well grown, it produces a stem 2½ ft. high, which, when covered with bright crimson blossoms, is rather a striking object.—Mr. Crawford, gardener to Mrs. Arabin, sent a cut specimen of Solandra grandiflora, a beautiful hothouse shrub, having large showy white bell-shaped flowers. It was introduced from the West Indies a great many years ago, but on account of the difficulty found in blooming it, it is not generally cultivated.—From Mr. Doran, gardener to T. Hawes, Esq., was a brace of straight, well-formed Cucumbers, measuring 19 ins. in length: a certificate was awarded for them.—From the garden of the Society was a collection of plants, comprising Oncidium amplistum, both the small and large variety; they were sent from Guatemala by Mr. Hartweg, and are both one species, but differ in the size of the flowers, the one being much larger than the other. It is one of the many instances in which Orchidaceæ differ in this respect; it seems to be a general disposition among them, for plants of the same species to produce flowers different in size, while in other respects they are not dissimilar. In the same collection were likewise Dendrobium Heyneanum, Epidendrum Stamfordianum, Lycaste cruenta, Franciscea Hopeana, Euphorbia melanthera, and three Cinerarias, viz. Fanny Tripet, Urania, and Unique; which had been drained with charcoal, the second had been top-dressed with the same material, and the third, besides being top-dressed with charcoal, received one teaspoonful of Harris's liquid manure to a pint of water, on the 5th of February. With these differences, the plants were treated in every respect the same. The first was the smallest, and the leaves were of a pale yellow green; the second was larger, and the foliage was of a deeper shade; the third, being the one that had received the liquid manure, in addition to the top-dressing of charcoal, was the largest, and the leaves were of a very healthy dark green; but that this results from the use of the liquid manure is not perfectly ascertained. Along with these were cut flowers of Camellia Colvillii, imbricata, and Reevesiana; and also of Acacia pubescens, and Riceana. The following cuttings of Pears were distributed:—Comte de Lamy, a Belgian variety, middle-sized, very sugary and rich, and in perfection in October, Thompson's, also of Belgian origin; it was received from Dr. Van Mons; and although it possesses great excellence, it has not yet been discovered among the more recent importations of new varieties from the Continent, received with names; it is by many esteemed the richest Pear of its season, which is November. Winter Crassane, one of Mr. Knight's varieties; it is an abundant bearer, as a standard quite hardy, of the form and size of the Crassane, with its flavour and less grittiness: it comes into use in December or January. Althorp Crassane, also raised by Mr. Knight, and hardy like the preceding: specimens of it have been found of excellent flavour, although grown in a much worse climate than that of London.

LINNÆAN SOCIETY.

Mar. 19.—EDWARD FORSTER, Esq., in the chair.—Thomas Bridges, Esq., was elected a Fellow. A collection of fruits was exhibited, presented to the Society's collection, by John Reeves, Esq.—A spurless variety of Tropæolum was exhibited by Mr. Hugh Low.—A paper was read from George Newport, Esq., on the structure and classification of the class Myriapoda. The author stated that this class had received less attention than any other belonging to the animal kingdom. Dr. Leach had left materials at the British Museum for their further study, of which the author had availed himself. This class was placed by many systematists with the insects; but they differed from the true insects in many respects. They were more like the larvæ of insects. They differed from insects in being born with a small number of segments, which go on increasing and lengthening the body of the animal, till it has attained maturity. Insects always have the same number of segments. In true insects the legs are only six in number; but in the Myriapoda, each segment is furnished with several legs, and in some species they amount to 160 in number. The Myriapoda were not more nearly allied to the Crustacea and Arachnida, but there were species pointing out an affinity with each of these classes. In arranging the Articulated classes, the author considered this group ought to be placed next the Vertebrate division, and he placed the insects at the top of the Articulated classes. He did so on account of the larger developments of the supræsophageal ganglion in this class, which must be looked upon as the representative of the brain in the vertebrate classes, and which accounted for the superior instincts and intelligence which those animals exhibit. In the arrangement of the whole group, he should not take alone the digestive apparatus as his guide, but the skin, the organs of locomotion, and the nervous system, as it was on these organs that the functions of animals depended, which most clearly distinguished them from the vegetable kingdom.

Reviews.

A Treatise on the Cultivation of the Pine-apple, &c. &c. By Joseph Hamilton, Gardener to F. A. Philips, Esq. 12mo. Masters.

THE author of this book is the grower of the large Thornfield Pines, mentioned at p. 861 of our Journal for 1843, and on previous occasions. He is, therefore, a man of authority, and his method of cultivation will be read with interest.

The weight of Pines grown by him is stated by himself (p. 93) to be as follows:—"The Montserrat has been frequently cut here, from 6lb. to 7lb.; 20 Montserrats have been cut the last two years, viz, 1841 and 1842, which in all weighed 104lb., the largest of which was 7lb. 4oz., all out of one house. The Black Jamaica generally speaking runs rather larger. The majority of the Enviles cut at this place vary from 7 to nearly 9 lbs."

And he adds, that in his opinion—"A Queen of 5lbs. is equal to a Montserrat, 5 lbs. 4 oz., Black Jamaica, 5 lbs. 8 oz., Enville, 7 lbs., White Providence, 11 lbs.;" long experience having taught him, that to grow the above varieties to the weight specified above, deserves equal merit. These things will enable the reader to judge in some measure of Mr. Hamilton's skill.

The first fifty-seven pages consist of a brief and useful sketch of the plans of Pine Growing employed by former gardeners, from Welend up to Marsland; but, strange to say, not a word is said of Mr. Glendinning's, which is the best of them all; nor of Mr. Barnes's, published in the January Number of the "Gardeners' Magazine," and which might have been introduced into a note at the end of the work. Mr. Hamilton next sets forth his own mode of proceeding, which occupies forty-five pages. The main points on which his practice seems to depend are: 1st, Fruiting the suckers of old stools; 2d, Turning his successions out of their pots into a tan-bed, in which they fruit, and through which their roots find their way without let or hindrance; and, 3d, Watering the plants overhead. His mode of proceeding with suckers is stated at considerable length. We can only make a few extracts:—

"The plant being ready for its last shift, I commence by putting two or three inches of broken Oyster-shells, mixed with a little bone-dust, at the bottom of the pot as drainage; on this I place a covering of half-decomposed turf, and then turn the plant carefully out of its pot, re-removing a little of the soil from the bottom of the ball, in order to have it a good depth in the pot, so as to allow room for soiling up after the first fruit has been cut.—I am quite convinced of the superiority of earthing up, over that of transplanting into larger pots, after the fruit has been cut. I have frequently tried the latter as an experiment, and invariably found the plant to be from two to four months longer in fruiting, and the fruit also to be much inferior in size.—The plants after earthing up will commence growing immediately, and new roots will be thrown out from the bare trunk into the fresh soil.—By attention to watering, moist atmosphere, &c., the suckers will grow rapidly, and perfect their second fruit, generally speaking, in from eight to twelve months from the time the first was cut.—With me it invariably happens that all the varieties of the Pine that I have cultivated, except the White Providence, have one sucker or more in progression, whilst the plant is swelling its fruit; in such cases one only ought to remain, the others should be destroyed as they appear, except the cultivator prefers quantity to quality.—After the fourth fruit has been perfected, I then cut off the sucker which produced the last fruit, with from six to eight inches of the old trunk attached to its bottom. The leaves are all dressed off that portion of the detached trunk, and from the bottom of the sucker, which will have made a quantity of roots in the axil of the leaf of the detached trunk, is then planted into a pot, nine or ten inches diameter at the top, placing the attached trunk at the bottom of the pot, before the drainage is put in, in order that the sucker may be sufficiently deep to be covered with the soil.—It must be observed that by the practice of planting a portion of the old trunk, with the sucker, although the former when first planted, has frequently no roots, it undoubtedly assists in supporting the sucker until it has made roots of its own; and this I ascribe to the sap or juices already deposited in the trunk, which are very probably set in motion by the chemical agency of the soil. The plant being a succulent one, is capable of holding in reserve its accumulated food in a fluid state, for a great length of time, and particularly if screened from the powerful rays of the sun."

The method first employed in turning the succession plants out into the tan-bed is thus described:—

"On February 26th, 1828, I planted 48 Pine-plants in the tan-bed, all of which, except one, fruited the same year. The process which I adopted was as follows:—The pit in which they were grown was 27 ft. long, by 10 ft. wide inside; two feet of which were occupied by the flues and cavities, which left a width of 4 ft. for the tan-bed. After all the plants were taken out of the bed, the old tan was levelled, well trodden down, and smoothed with the rake; the whole bed was then covered with fresh tan to the depth of 10 inches; the plants were then immediately turned out of their pots, with their balls as entire as possible, and plunged into the bed; they were then beaten tightly about the ball, and covered to the depth of one inch only. It will be necessary here to observe, that if the ball, with the roots, be covered too deeply, they will be in danger of being burned. The tan used for this mode of culture must be made from British bark, as it undergoes a slower putrid fermentation than foreign tan; and I have always found that as it decays it is rendered less fit for supplying the plants with food. I have tried planting in old decayed tan, but the plants made very little progress: the fruit also was of inferior size. Foreign tan is objectionable, as it soon decays."

Afterwards it underwent some variations.

"Thinking, however, a great improvement might be made in this method of planting out into the tan, I tried the following experiment, which fully answered my expectations:—At the time the plants were showing fruit, I added two or three inches of fresh tan all over the roots of twenty, beating it down with the spade, and the beneficial result was seen in the swelling of their fruit. By the time this was cut, the suckers then growing on all the plants were of a prodigious size, and had I then known the value of their produce, by letting them remain attached to the old stools, their second fruit might have been ripened by the following October."

The reason why tan is found a better plunging material than anything else, is, in Mr. Hamilton's opinion, its warmness; for he found that the best kind of compost was too cold. And this we quite believe. But we should like to know whether tan would be found better than rich soil, if bottom-heat were supplied by hot-water gutters. We should expect it would *not*.

Upon the importance of watering overhead with *warm* water, Mr. Hamilton much insists. Indeed, he also keeps the atmosphere damper than is usually thought necessary. At page 65 he says—"I only water the plants over their leaves in the evening, at the time of closing the house, which ought to be done whilst the sun is still shining on the glass, before its rays are much diminished, thus causing the heated particles of the water, which have been sprinkled inside the house, to convert the superincumbent atmosphere into a state of humidity, which being inhaled by the respiratory organs, into the assimilating system, will assist the plant to promote those secretions indispensably necessary in maintaining it in health and vigour. It is also of much importance that the atmosphere be kept moist during the day, by throwing plenty of water in the alleys and other vacuities; the humidity arising therefrom will be absorbed by the plants, and thus the respiration and perspiration of fluids being perpetuated day and night, will

tend greatly to keep the plant in a vigorous growing state." And in another place he writes thus—"My motive for supplying the plant with a sufficiency of water, by syringing over the leaves, is twofold; first, I believe the epidermis of the Pine to be very porous, and therefore capable of absorbing a great quantity of its food by that process. Thus I syringe with tepid water," &c.

In this practice of pouring water on the leaves, we have no doubt that Mr. H. is right—*at certain seasons*—that is to say, when the plants are growing *fast*; for that is what naturally happens to them, and what the peculiar arrangement of their leaves is manifestly intended for. But we greatly fear that it will have a bad effect upon the *quality* of the fruit, if followed up after the blossoms are withered and swelling begins. At that period, Nature gives the Pine-apple a hot and dry atmosphere, which is doubtless required to bring out its rich secretions; and all the moisture it obtains is from the soil.

We should like to hear, from disinterested persons, what the *quality*, that is flavour, of the Thornfield Pines has really proved to be. In the meanwhile, we reserve some more special remarks on Mr. Hamilton's work for another opportunity.

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

ARCTOSTAPHYLOS PUNGENS. Pungent Bearberry. (*Evergreen Shrub.*) Ericaceæ. Decandria Monogynia.—This seems to be a common Mexican shrub, for it occurs in most collections from that country. In appearance it is extremely like Arctostaphylos tomentosa, and an insufficient examination of dried specimens led to the belief that it is a mere variety of that plant. The fresh specimens show, however, that in addition to a want of the long beard-like hairs of the branches of A. tomentosa, this species has the awns of the anthers longer than the anthers themselves, and only seven cells to the ovary instead of ten. It was introduced to the garden of the Horticultural Society by Mr. Hartweg, who found it in Mexico, at an elevation of 7000 to 9000 feet above the sea, forming an evergreen shrub six to eight feet high, with a reddish brown smooth stem and branches, and very hard wood. It was common about Guanaxuato, Real del Monte, Bolanos, and Oaxaca, and is known there under the name of "Pinguica" or "Manzanilla," according to that Botanist. Up to the present time it has proved, in cultivation, to be a neat little half-hardy or possibly hardy evergreen shrub, growing two or three feet high. But it is one of those uncertain plants which will die suddenly during the hot weather in July and August, especially after a few hours' rain, if planted in the open border, although it may have been previously in the highest state of health and vigour. Mr. Gordon, who has had the management of it in the garden of the Horticultural Society, has given us the following note concerning its management:—"It seldom can be kept alive for more than two or three seasons after being raised from seeds, even in pots, unless treated in the following manner:—The seeds should be sown in pans, filled with a mixture of peat and loam, to which should be added a small portion of decomposed cow-dung, and placed in a close pit or frame. They soon come up if sown in the spring or summer, but if sown late in the autumn the seeds lie in the soil until the following spring before they vegetate. When up, and before they make a rough leaf, prick them off into a fresh pan filled with the same kind of soil as that in which the seed was sown. Afterwards keep them shut up close and well shaded, and finally pot them off singly when they have made three or four proper leaves, giving them at once a shift into larger pots, and return them to the frame, which should now have the back turned to the sun, and be kept close for a few weeks; air not being given at any time until the plants are fairly started and growing again. Afterwards remove the lights entirely during the night time, and keep them on quite close in the day, during the summer and autumn. When the nights become wet and frosty, remove the plants to a cold pit for the winter, where there is plenty of light and air and no damp."—*Botanical Register*

BERBERIS PALLIDA. Pale Ash-leaved Berberry. (*Evergreen Shrub.*) Berberaceæ. Hexandria Monogynia.—To the pinnated, or Ash-leaved, Berberries, formerly miscalled Mahonias, Mr. Hartweg has been able to add seven new Mexican species, among which is the plant now described. In its native country it forms an evergreen shrub from five to six feet high, and is found but sparingly near Cardonal and Zimapan, on mountains thinly covered with Pinus Llaveana. Mr. Hartweg also met with it near the hot springs of Atotonilco El Grande, but nowhere in any quantity. That gentleman informs us that it is easily distinguished by its dry hard leaves, and pale yellow flowers; and that the wood is also of a lighter colour than in any other species. In our gardens its appearance is vastly improved, and it will probably prove as handsome as others. It grows freely when potted in a mixture of sandy loam and leaf-mould, to which is added a small portion of rough bone-dust. Being at present extremely rare, it has not been tried in the open border; but the appearance of the plant leads us to suppose that it may be at least as hardy as B. fascicularis. Up to the present time, in the garden of the Horticultural Society, it has been kept in a cold pit. It may be increased like the other pinnated kinds, by grafting on the common B. aquifolium either in spring or autumn, when the young shoots are nearly hard; but hitherto the plant has not shown the least disposition to make any lateral shoots, although three feet high. It will, no doubt, be increased hereafter by seeds, which are likely to be produced freely when the plants get older; as yet the Berries have had no seeds in them. It flowers during the months of January and February, if kept in the greenhouse, and in July ripens its long erect spikes of deep purple Berries.—*Botanical Register.*

Miscellaneous.

*Propagation of Plants by Circumposition.**—The following mode is practised by M. Fonlup, at Mont-Brison. He procures a quantity of small tin cases of a conical form, like the upper part of a funnel, 2½ inches in length, and 2⅛ inches wide at top, narrowing towards the lower part till only sufficient room is left for the introduction of the shoot or branch intended to be propagated. These cones are supported on rods, to which they are secured by wire. Commencing with the central branches, the leaves are taken from the parts which the tin is intended to inclose. The branch is cut two-thirds through, as in layering; and being inclosed by the funnel the latter is well packed with moss. Moisture, necessary for favouring the emission of roots, is supplied by means of a bottle from which the bottom is struck off and the neck furnished with a cork, perforated so as to admit a small pigeon's feather or bit of wool, to form a syphon, by means of which the moss is kept in a proper state of moisture. The plants on which the operation is made are placed so as to be partially shaded by trees during the first month. Hard-wooded plants are propagated in this way from the middle of May till the end of June; and the branches are sufficiently rooted to be taken off by the end of September. Soft-wooded plants may be operated upon in March, and the plants taken off in June, or in the end of June and beginning of July, in which case the plants may be taken off, if sufficiently rooted, in the end of September. It is, however, necessary, in all cases, to ascertain whether the branches are sufficiently rooted previously to their being separated. This is easily done by opening up the edges of the tin. When the branches are found to be sufficiently rooted they are potted off without removing the Moss by which the roots are surrounded. Being moderately watered, they are immediately placed under glass, on a slight hotbed, and kept shut up for a fortnight. They are then gradually exposed, and afterwards placed in the shade of large trees, so that only half the rays of the sun shall reach them. In this manner M. Fonlup obtained from one stool of Pittosporum sinense, 52 well-rooted plants in the short space of two months, by means of 30 tin cones. He also employs the latter for invigorating weak branches, and for increasing the size of fruits.—*Revue Horticole, for Sept.*, 1843. ‖

M'Nab Testimonial.—At a dinner lately given to Mr. M'Nab, the following articles were presented as the result of the late subscriptions, viz., a silver snuff-box enclosing a draft for 400*l.*, on the Edinburgh and Glasgow Bank; also another snuff-box fashioned like a Scotch Thistle, and formed out of the root of a Scottish Bamboo, grown by Mr. M'Nab in the Botanic Garden; and it was stated that the cane from which it was taken grew to the height of 40 ft, in the short space of six months. A silver salver, silver divider, and silver sugar-basin were likewise presented to Mrs. M'Nab, and a work-box bearing an inscription was given to Miss M'Nab, who has drawn a well executed portrait of her father, which is to be given to every subscriber.

African Guano.—We lately announced the arrival of African guano at Liverpool. We are now enabled, by the kindness of a friend, to give its analysis, as obtained by Mr. Huson of Liverpool.

Guano from Ichaboe, Western Africa.

Moisture (water)	16·3
Free Ammonia	6·5
Ammoniacal salts, chiefly urate and phosphate of ammonia	52
Carbonate of lime	6
Organic (animal) matter, with phosphate of lime, traces of oxide of iron, and an inappreciable amount of silica	19
	100

[If this analysis is correct, there can be no doubt that the substance is of great value.]

Hamburgh Botanical Garden.—The friends of Mr. Edward Otto, son of the botanical veteran, will be glad to learn that he has been appointed Superintendent of the Hamburgh Botanical Garden, an establishment provided by the government of that republic, for the use of students and lovers of our science. Mr. Otto will assume his office in the middle of next month, and it is, as he writes to correspondents, his wish and hope to keep up an active and useful intercourse with his many friends on this side of the water.

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

PROPAGATION and potting will occupy the greater portion of the time here for the next six weeks; attention must also now be directed to training and regulating the young growths of climbers and other free-growing plants. Newly potted plants do not want much water until they are more established in the fresh soil; bulbs of the Amaryllis tribe brought in for forcing may be potted, if they require it, when their leaves are half grown, but never pot them when they are at rest; the heat and moisture may be the same as recommended for the last few weeks.

Conservatory.—The temptation to collect all plants in flower into this house being great, you may be led into error, by crowding them too much at this early season; crowding plants in winter is a matter of necessity, and when the plants are in a dormant state this is of less consequence, but now that they are in active growth, unless they have room to admit light and air among them, they soon spindle up out of all shape and proportion; except on fine days, little air is necessary for this house in March, and might prove very injurious to tender flowers. Camellia blossoms are as soon affected as any by cold currents; damp the paths in the evening, and light gentle fires at night while the weather keeps cold, and do not let the temperature get below 40° for the season.

Greenhouse.—The great facility and economy of heating ranges of pits now, and the superior manner in which plants grow in such pits, will do away with greenhouses altogether in a few years; this will make a great improvement in small places, where all the plants are now packed together in a neat little greenhouse, and where many of them die yearly, under the greatest care that can be given them; such little greenhouses will then be devoted to plants in flower only, except perhaps a few good specimen plants in winter. In the meantime keep this house as cool as possible—our nights are too long yet, and we have too little sun to preserve early growths properly; great attention is necessary in watering here now, as the plants soon get dry in fine weather.

Forcing-pits.—Bulbs of the Amaryllis tribe, or other kinds brought in for forcing, often make fine large leaves, but show no blossom, and on that account anyout of the way place is thought good enough for them afterwards; but the less these are disposed to bloom the more care is necessary to cultivate them, to expose their leaves as much as possible to the light, to see that they have neither too much or little water, and that their pots are well drained; turfy loam, with a little leaf-mould and sand, suits a great many of these; peat is injurious to some of the more delicate sorts of them, while the most tender of the Iridaceæ will live only in light peat. Always keep up a good moist growing heat, of from 56° to 60° in these pits from this time, and smoke them as soon and as often as the fly appears, but avoid strong doses; better do it often and give a little at a time.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

IF the directions of former Calendars relative to seed-sowing have been attended to, it will not be necessary to sow any more at present; but if not, a general collection must be got in without delay. The last few days, though they have been piercingly cold, have been favourable for the performance of out-door operations, and though the ground is in tolerable good condition, it will not be advisable to use the rake much on the beds until the end of the month. It will, however, be well on heavy land, to hoe it deeply, so as to get as great a depth as possible in a free pulverised state prior to planting out the half-hardy plants. Recently-transplanted annuals will suffer much during these parching winds, if they are not protected by a few branches or some other contrivance. Ply the broom and roller vigilantly, both on the lawns and walks, and above all things get the Grass cut well into the "bottom" before the middle of next month, or you will be troubled with it throughout the season. Snowdrops are now on the wane, therefore remove the flowers, and strengthen the bloom for another season. These simple things, though they take good care of themselves, are not unworthy of a little cultivation.

Rockwork.—This, where it is covered with plants, is one of the most difficult things in the garden to manage, without the plants being destroyed on the one hand, or a character of stiff formality imparted to it on the other. In regulating the plants avoid everything like formality, and while you keep each plant in due bounds, do not, if you can possibly avoid it, distort the symmetry of Nature. A little fresh peat or leaf-mould may be added as a top-dressing to the more choice of the Alpine plants, and a few seeds of trailing annuals may be sown in any vacant places.

Pits and Frames.—Many of the established and more hardy plants in these structures may now be removed to temporary pits to make room for the spring-struck stock, which are now being daily potted off. Some judicious remarks on this subject were offered by Mr. Errington three weeks back, which, though they do not accord with the practice of the best metropolitan cultivators, are nevertheless worthy of consideration. For my own part I imagine that plants should not be kept in a perfectly shaded situation from this time until June, merely because it happens to be good treatment for them from November until March, when they ought to be in a perfectly dormant state. My practice, which extends to upwards of 20,000 plants annually, is to get the plants growing as soon as the natural season will induce them to do so, so as to get rid of that rusty appearance which is always attendant upon plants that have been shaded for a few weeks after they are first planted out. Proceed with potting off, and do not permit any vacant space in the propagating frame until you have more plants than you require for bedding out.—*W. P. A.*

III.—FLORISTS' FLOWERS.

THE boisterous winds of March are anything but congenial to Florists' Flowers; and the frosts that we may constantly expect, must be guarded against with redoubled care; for every Florist knows that more havoc is made amongst their collections during the present month, than at any period of the year. The Auricula is very susceptible of cold when expanding its blossoms; and, should the temperature of the frame get too low, it is with the greatest difficulty (and with some sorts wholly impossible), that they are enabled to bloom. The crop or stock of Carnation layers is much below the average, many growers complaining sadly of the loss they have sustained. When the nights are likely to be fine, the frames ought to be left open, so that the plants may be hardened preparatory to their removal into blooming pots. Very few Ranunculuses ought now to be out of the ground. Seed may still be sown with success. *Pinks* appear to have been rather affected by the late winds; all cracks in the bed must be closed, and the plants looked over after frosts, and fastened. *Polyanthuses* are rapidly growing; care must be taken to trap snails and other insects injurious to the forthcoming blossoms. Under this head we may just observe, that "we" are not in the habit of asking fictitious questions on the Polyanthus, and then "*modestly*" answering them ourselves. *Pansies.*—Would amateurs and cultivators for sale discard from their stocks all varieties with undecided body-colours, flimsy petals, and bad forms, one half the flowers in the published lists of the present season would be ejected. We are rather fastidious in the matter of Pansies; but the following may be relied on as prime show-flowers, combining shape, purity of ground, and distinctness of colour, joined to perfect marking:—Pearson's Milton, Sobiraki, Macgraith and Black Prince, Gibbons's Belle du Monde, Prince of Orange, and Sovereign, Duff's Enchanter, and Bridesmaid.—*T. F. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—With the increased light the plants now enjoy, they will bear a greater degree of excitement by bottom-heat, as well as a warmer atmosphere. The fruiting plants may now have a bottom-heat of 85° at a depth of 9 inches from the surface. If the heat exceed 95° at the above depth, it will be requisite to draw a portion of the tan from the sides of the pots, or to use some other means to let the heat escape. The plants intended to fruit in the autumn should have from 80° to 85° of bottom-heat, and the same for the younger successions. The safest way of ascertaining the degree of bottom heat is by the thermometer. The heat-sticks in common use do very well for practised men, but the unpractised should not depend upon them, and it is of the greatest importance to be careful that the bottom-heat is of a proper degree. Shade those plants potted in February only during very clear sunshine. Be careful not to give much water to newly-potted plants, till it is ascertained that they are rooting freely.

Vinery.—Attend to the directions given last week with regard to thinning, tying, and stopping. Look well to the state of the heating material on the outside borders; for, if the heat is allowed to decline now, it will prove very injurious to the Vines and crop. Any healthy Vines, but not of good kinds, should be inarched before the wood gets too old.

Peach-house.—Continue the treatment recommended last week. Where it is intended to force Peaches, Apricots, or Cherries, in pots next season, and some suitable plants have to be provided, it should be no longer deferred. It is a good plan to pot some good maiden plants every year to succeed any that are becoming useless.

Figs and Cherries.—See last week's Calendar.

Melons.—Many will now be preparing to plant out their first Melon plants, and it is indispensable to success that the plants be strong and healthy at planting. Take care that the heat is "sweet," and that the soil is in a medium state of dryness. Those plants turned out in February ought now to be rooting freely. If the roots are appearing through the hills or ridge upon which they are planted, encourage them by adding a few inches in depth of soil of a rough turfy texture; the soil should be of the same heat as that in which the plants are growing. Keep the shoots in their proper position by tying or pressing down.—*G. J.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Protecting Peaches and Apricots.—A temporary wood coping, of from 12 to 15 inches in width, is of great advantage. Screens of woollen netting or thin bunting are preferable to thicker materials, as when the latter are used they must be drawn up or aside once a day, when the blossom or fruit is as apt to suffer from unobstructed bright sunshine as from slight frosts. Where these materials are wanting, or too expensive, a good substitute will be found in straw ropes, twisted rough, so as to leave part of the straw hanging out; these, 18 inches separate from each other, and fastened to poles 9 feet apart, constitute a good pro-

* This term was employed by early writers on gardening, but has latterly fallen into disuse. In the "History of the Propagation and Improvement of Vegetables by the concourrence of Art and Nature," by Robert Sharrock, Fellow of New College, Oxford, 1660, layering and circumposition are thus defined:—"Circumposition is a kind of laying; the difference is, that in this, the mould is borne up to the bough which is to be taken off; in laying, the bough is to be depressed into the mould. Such plants are propagable this way that might take by laying, but that the branches are too far risen from the ground to be laid along therein; and therefore it becomes necessary, since they cannot stoop to the earth, that the earth should be lifted up to them."

tection. Apricot-blossoms appear to be very thin in this neighbourhood, owing to the wood being imperfectly ripened. *Pruning and Nailing.*—Finish all sorts as soon as possible. *Planting* should now be attended to, in favourable weather. All young trees should have their roots hampered in a puddle as soon as taken up, to prevent the young fibres being dried up. *Carrots, Parsnips, and Onions.*—Sow the first main crops, if not already done. In wet stiff soils, cover the seeds with some dry soil. Sow almost everything in rows, and then any one may clean and thin. *Basil, Balm, and Scorzonera.*—Sow a little of each for early use. *Potatoes.*—Get in the main early crops. Spring ones may be planted in beds intended for late Celery, as previously recommended. *Pits and Frames.*—Keep up the heat to Cucumbers. Grow them quick, if you want crisp fruit. Give plenty of air to Potatoes, Carrots, &c., in order that the frames may be removed shortly for other purposes.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—There will be nothing particular to do in this department but what has been previously recommended, till the bark season commences.

Coppices.—Now that the weather seems to be more favourable, all the work recommended to be done at this season in former Numbers, should be completed as soon as convenient. Cutting of hedges, corf rods, poles, &c., will do well *for* some time yet, particularly Birch, and some of the more copious bleeding kinds.

Young Plantations.—Works previously recommended should be forwarded with all possible *haste*. When the ground is a little firm, and before it becomes too hard, go over all newly-planted trees, and placing them upright fasten them firmly in the ground by various *means*, according to size and other circumstances; also mulch any choice sorts.

Hedge rows.—Neglect nothing that requires doing at this season, which has repeatedly been adverted to in previous Nos.

Nursery Work.—As soon as the ground is in a favourable state, proceed with all necessary work; complete the planting of seedlings, and small plants taken up. Plant Larch and early budding kinds first; sow seeds, kernels, nuts, &c. of forest-trees and shrubs, and fasten all newly-planted trees and cuttings, that have been lifted up by frost, as soon as the ground is in a favourable state.—*W. B.*

State of the Weather at Chiswick during the last 18 years, for the ensuing Week ending March 30, 1844.

Mar.	Aver. Highest Temp.	Aver. Lowest Temp.	Mean Temp	No. of Years in which it Rained.	Greatest quantity of Rain.	Prevailing Winds.

March 15th Rain; fine; clear and fine at night
16th Slight haze; fine; densely overcast; boisterous
17th Overcast and cold, with easterly winds; cloudy and boisterous
18th Clear; cold and dry; overcast at night
19th Cloudy and cold; overcast; fine
20th Cloudy; rain; boisterous, with hail-showers in afternoon, and at intervals calm and sunny; clear and frosty
21st Sharp frost early; very clear; sunshine; clear, with slight frost at night

Mean temperature of the week, 4 deg below the average.

Notices to Correspondents.

ANEMONES.—*R. V.*—Procure some good sandy loam and well-decomposed cowdung, and mix them in the proportion of three-fourths of the former to one of the latter. If the loam is stiff, add a sufficient quantity of fine sand, to make it free. Having thus prepared the compost, procure some 24-sized pots, and drain them with a few potsherds, putting over them a layer of fine charcoal, which is excellent for bulbs, independent of its preventing the admission of worms. Then pot your roots of Anemones and Tigridias, putting three or four roots (less or more, according to their size) in each pot, and placing the pots in a cold frame or pit, where they will be free from frost and damp. When they are up, admit air freely in fine days, otherwise they will become drawn and will not flower well, nor will they remain long in flower. After they have done flowering, remove them to a shady situation, and supply them plentifully with water at first, reducing it as the leaves begin to turn yellow, and, finally, allowing them to become quite dry, in which state they may remain all the winter. Some of the Anemones might be potted in the autumn for an earlier bloom. The bulbs of Tigridia keep much better all the winter if they are allowed to remain in dry soil in the pots they were grown in.¶

ASPARAGUS.—*Ponterdulais.*—Now is the time to prepare your beds for sowing the seed; but it is getting too late to plant the beds with seedlings. Sea water is most advantageously applied when the summer shoots are about 6 inches high.

AURICULAS.—*A Subscriber.*—Although a Cowslip and a dark Auricula were planted in conjunction, the colour of the blossom of the Cowslip would not partake of the dark colour of the Auricula bloom.‡

BEES.—*A Lady.*—A "Nutt's hive" does not prevent Bees from swarming. The unusual proportion of drones in the old stock was an evil, but the greatest was being weakened by its offspring and the bad season. The supply of food in autumn does not seem to have been sufficient. Probably many of the Bees were induced to leave the hive on account of the mildness of the winter, and perished in search of food. Those that died in the hive would be cast out by the famished inmates. The empty combs will be of great use when the hive is replenished again with another swarm.—*J. W.*——*J. T.*—The single-leaf hive is the best for experiments. A good plan of it is given in Dr. Bevan's work on Bees. But if you wish a wooden hive with windows, merely for observing the insect's at work, and expect part of their treasure, the collateral, or Polish hives are the best. You ought, however, to be careful in purchasing a hive, as some are made more for show than real utility. Mr. Wighton, in his book on Bees, mentions a very simple plan of constructing a Polish hive.—*W.*

BEET.—*A W.*—The sweet flavour in the root seems to depend much on the soil; for the best sorts will taste earthy in some gardens, where inferior kinds are not so. The red Castelnaudary, when it can be obtained genuine, is best coloured; and it is much esteemed for its superior flavour. It is small in its whole habit, and, occupying little space, may be sown closer than other kinds. Beet requires a deep, rich, and rather light soil, to prevent its growing forked; and being impatient of frost, it should not be sown until all danger of destruction from that is over.‡

BOOKS.—*E. B.* must consult the advertisements.——*G.*—Gloxinias on the Pine-Apple by all means.——159.—No man can be a good gardener by reading books. Gardening, like all arts, requires practical experience. Loudon's "Suburban Horticulturist" may perhaps answer as well as any.

BROCCOLI.—*Rambler.*—See p. 153.‡

BURNT EARTH.—*Rural Chemistry.*—All plants will be the better for this, if it is mixed with the soil in which they grow.

CELERY AND CELERIAC.—*Rambler.*—It will be worth while to grow, or at least attempt to grow, Celeriac instead of Celery if you prefer using the former; but if your soil be not adapted for it, that is, if it be a rich loam, and not sandy, you will find its cultivation will be a more difficult matter than that of preventing your Celery from "running away or piping."‡

CHARCOAL.—*S. S. S., and Others.*—We want much a good and *cheap* contrivance for charring charcoal, peat, and similar substances. At present, every one must act upon his own judgment. The principle is, to form the charcoal with as little access of air as can be secured; otherwise, the woody matter will be reduced to ashes. Possibly, the cheapest contrivance in the long run, would be to construct an iron chamber, into whichthe wood, &c. can be introduced, and then to surround the chamber with fire. A small chimney or sock in the chamber, would allow the smoke and volatile matters to fly off.

CLIMBERS.—*A Lady* may cover her wire trellis with Jasminum revolutum, Lophospermum scandens, Convolvulus major, and Eccremocarpus scaber.‡

ENGINE-ROOMS.—*W. T. W.*—Nothing but stove plants will succeed in an atmosphere of 60° to 70° by day, and 70° to 80° by night; and they not well, because the natural difference of temperature between day and night is reversed. It is indispensable to the majority of such plants that they should have a damp atmosphere; and you possibly might obtain that by plunging the pots in a thick bed of bog-moss (Sphagnum) well wetted, or in refuse sponge clippings, if they can be had. What are called dry stove plants, such as Aloes, Stapelias, Cactuses, Mesembryanthemums, Echeverias, and the like, would suit you best. Can't you manage a Ward's case? In it you might grow any kind of small stove plants, if you can get light freely.

FIGS.—*D.*—Two good varieties of Fig for the open wall are, the Brown Turkey and the Brunswick. So long as the tree you already possess bears abundantly, there is no necessity either for cutting its roots or allowing it to ramble above the wall. Thin out some of the branches, in order to make room for a fresh supply of bearing-shoots, near the base. Protect the extremities, the bearing portion of the shoots, from the early frosts of autumn most especially.‖

FRENCH BEANS.—*A Subscriber.*—The cause of your French Beans dropping their blossoms is no doubt owing to cold and damp combined; but, from what you say, principally from the latter.‡

FRUIT-ROOMS.—*N. V.*—Your fruit-room window should face the north, and it would be advisable to have shutters on it, so as to be opened or shut as required.‡

FUNGI.—*An Inquirer* must permit us to class under this head the information he has received. We cannot answer the question about the Botanic Garden. Why not write to Mr. Maund?

THE FIG.—*Clericus.*—If your Fig-tree does not bear, it is owing to some other cause than the advance of another tree in its neighbourhood. Caprification is not required in this country. If, however, your fruit swells pretty well, and then drops off, try the effect of moistening the eye of the Fig with a little sweet-oil, at the time when it is open.

GRASS SEEDS.—*Ponterdulais.*—The Grass which smells like new Hay is the Sweet Vernal (Anthoxanthum odoratum); but it is of no use in a lawn. The best for that purpose are the Crested Dogstail and Meadow Poa. Certainly put down your Calceolarias, &c., if the old stems are on them; but there is no advantage in doing so with the new shoots. All Greenhouse plants should be repotted now, if they are to be fine; if you do not care for that, you may let alone such as are to be turned out in June.

HEATING.—*R. S. D.*—Will not the Heckfield-pit plan at p. 892 (1843), or another in to-day's paper, answer your purpose? They are both excellent in different ways.——*M. J. R.*—Your tank is unnecessarily deep; six inches are enough. We do not otherwise object to your propositions. Iron will, however, be much better than wood and stone, if you do not mind a little present expense. All, however, depends on the degree of forcing you wish for. If it is only to bring Grapes a little forward, then wood and slate will do well enough. All the modern boilers are sufficiently good, and we should, for such a job as yours, take the cheapest. There is more difference between many of the boilers in theory than in practice. A good iron boiler well set is quite as useful as one of copper, unless you want to have it exposed to view.

HOTHOUSE BULBS.—As you are an *early member* you may refer to various answers to correspondents, and to the Indexes of former Volumes, for the information you seek. The cultivation of each of the bulbs you inquire about has been *fully* explained on former occasions.

HOTHOUSES.—*N. N.*—Your plan for propagation is unobjectionable, provided you can prevent the materials in your bed from becoming dry, in consequence of the action of the pipes. It would be desirable to place upon them an evaporating-pan. The Cannon Hall Muscat is different from the common Muscat, but not better.

INSECTS.—*Peter Mackenzie.*—The beetle you found in the Beans is the Bruchus granarius, figured and described in last year's *Chronicle*, p. 188. It is not the same which eats the edges of the Bean leaves.*R.*——*E. B.*—The insects in your Cucumber frames are the Acarus coleopterorum, which infests beetles inhabiting dung and putrid animals. They are conveyed into your frames, in all probability, with the hot muck, and a single diseased beetle, concealed in the earth or in a rotten Cucumber left for seed, would generate myriads of the Acarus in a short space of time. But are you convinced that these mites eat the roots of the Cucumbers? *R.*——*J. Took's* little beetle, which he considers a troublesome pest amongst his Cucumber plants, is the Hister (Abræus) minutus. We believe that he need not apprehend any mischief from its appearance; but should we be mistaken, we shall feel obliged by his correcting us. *R.*——*A. F.*—We cannot make out the name of the animal complained of as a pest in his Cucumber frames; but if he will favour us with specimens, we will advise him on the subject. *R.*——*A Lady's* Pelargonium-leaves have been eaten by some animal infinitely larger than those which were detected by her; but whether the culprit be the caterpillar of some moth, or a slug or snail, which probably ventures out at night only to feed, it is impossible to say, but by scheeching after dark the truth may be ascertained. *R.*

MANURES.—*G. S. T.*—The ammoniacal liquor of the gas works, is not gas-tar, but what they call gas-water, through which the gas passes in the process of purification.——*E. A. N.*—It is very troublesome to char saw-dust. It can only be done by great care in a sort of kiln furnace, expressly constructed for the purpose, and must be *quite dry.*——*Amateur.*—No doubt your Pernambuco Gourd will require the management of a Melon. We know nothing of it.——*Jack.*—We do not know what the effect of Potter's Guano may be on resinous trees, such as Firs; for other plants, it seems to be generally useful. Both Peruvian and Potter's Guano are far better than nitrate of soda; but the Peruvian requires to be reduced in strength by being largely mixed in the soil or cinder-ashes.

NAMES OF FRUITS.—*J. G.*—The Apple you sent is correctly named Hammond's Pearmain. It is a Suffolk variety, excellent as you describe it to be.‖

NAMES OF PLANTS.—*W. H.*—Cotoneaster microphylla ‡——*Jones*—Vestia lycioides.——*C. J. C.*—Catasetum discolor; not an uncommon species. You will hardly find twelve *good* varieties of Azalea indica, if you buy all that are on sale. Phœnicea, alba, variegata, interitia, and the old Indica are the best.——*W. Rayner.*—What you have got for Martynia fragrans is some kind of Kali!——*G. H.*—Your bulbs are small specimens of a fungus called Scleroderma vulgare.——*A Reader.*—Your plant seems to be Iria stellata, and not Stanhopea nobilis.

ORCHIDACEÆ.—*H. T.*—There are no exotic Orchideæ in cultivation that would succeed in a Vinery all the year. The dry atmosphere in summer necessary to colour Grapes, and the low temperature in winter required to ripen the Vines, would destroy the most hardy sorts.‡

PELARGONIUMS—*C. D. F.*—Your plants of these, that have been kept in a cellar during winter, should be replaced in pots as soon as possible. ‡

PHLOXES.—*A Subscriber.*—The following 12 are showy:—*Dwarf or early flowering kinds:* Phlox nivalis, white; P. procumbens, purplish blue; P. amœna, rosy red; P. setacea, pink; P. subulata, rosy purple; P. Nuttalliana, rosy pink. *Tall or late flowering kinds:* P. omnifiora, white; P. Brownii, crimson; P. picta, lilac striped; P. Van Houttii, purple striped; P. Coldreyana, bright red; P. tardiflora, white. We have had no experience with Potter's Liquid Guano.¶

PINES.—*A. N. S.*—The dung of deer or sheep or pigeons, steeped for a few hours in water and well stirred, then left till it is clear, will prove as useful as anything. We should not value the second infusion. The action of patent manures on the Pine-apple is unknown; but they are well worth a trial. The best Pines are the Queen, Black Jamaica, and Montserrat. None of the English-raised seedlings are first rate. The Cayenne Pine is from French Guiana; cannot state its price; that is the affair of the nurserymen. How can you suppose that the seeds of a plant infested with insects will also produce a filthy offspring?

POOR-RATE.—*A Constant Reader and a Rate-Payer.*—The overseer can demand the poor-rate after the quarter for which it was made, and there is nothing to prevent his collecting two rates for two different periods at the same time.

POTS FOR CARNATIONS.—*A. B.*—The pots commonly made and used for the purpose of blooming Carnations in, are called wide-mouthed 12s. Two plants are put in each pot, and they are made wide at the top for the convenience of layering the plants in.*

STOCKS—*Vectis.*—There is no means of distinguishing a double from a single stock before the flower-buds show; when they do show it is not too late to transplant the stock, if the operation is performed with care. ‡

STRAWBERRIES.—*A Novice* seems to have ruined his plants in pots by forcing them too quickly. If they are to be fine, the temperature of their forcing-house should be raised very slowly at first. Probably the Violets have been spoiled by similar means.

VERBENAS.—*A. Y. L.*—Six plants will be sufficient for a bed of Verbenas the size you mention; when they are planted peg down the branches in the direction of the vacant spaces; they will readily take root, and, sending forth fresh branches in different directions, the surface of the bed will soon be completely covered. We recommend you to procure V. Symondsii, which is a brilliant orange scarlet, a prolific bloomer, and one easily preserved in the winter. In September, when the plants are growing vigorously, it is a good plan to sink some small pots in the earth, filled with soil, and passing a branch over it peg it down upon the earth; the pot will soon become filled with roots, when it may be cut from the parent plant: these should be re-potted and encouraged, and when winter approaches put them into a cold frame, or bring them into the house; give very little water during winter.*

VINES.—*A Subscriber.*—It is not surprising that your Vines only four years old are now in a bearing state, after having been forced summer and winter, and sometimes prematurely stripped of their foliage by your predecessor. You cannot do better than cut them back in order to get good bearing-wood for next season.‖——*T. Y. P. R.*—It is a disputed question, and you had better put it to the test of experiment. If the laterals of Vines are permitted to grow without being stopped, they will probably injure the bunches; but the question is, whether it is not better to leave them and stop them than to destroy them entirely. Your gardener is right in not risking the experiment upon his own authority; but you can relieve him from the responsibility by directing the experiment to be tried.

WHITNEY'S VARNISH.—*C. Gyde.*—Your muslin is not so clean and white as Mr. W.'s, but it is as transparent, and will answer the same purpose.——*To a Constant Reader* we return the same answer; his, however, is not so good as Mr. Gyde's; that is, it is less transparent; but that may be owing to the stouter quality of the linen.

MISCELLANEOUS.—*Ignoramus, W. M.*—Although truth is seldom elicited by ridicule, yet you employ your weapons with so much good nature, that we would find room for your remarks if we could, and probably shall do so hereafter. In the meanwhile we would submit to you that it is not fair to expect from a mere gardener that degree of clearness which is demanded from a scholar, and that with the one, as with the other, the context will often show the writer's meaning, better than his actual words. Indeed, the old saying, *ex fumo dare lucem*, shows that educated men are sometimes sufficiently obscure in their language. If you will again read the editorial remarks you will find that they are used with considerable reserve, and relate to the general tendency of the articles criticised, and not to particular opinions, which of course *we* should not defend. We attach importance to these papers notwithstanding their obvious faults, and trust hereafter to convince you that although there may be a good deal of smoke it really conceals a reasonable quantity of light.——*W. B. B.*—A Walnut can only be *grafted* on a Walnut; the operation can only be performed when the tree is growing.‡——*A. B. C.*—Asphalte was advertised last week. For the purpose of preserving the points of stakes, we imagine that one kind is as good as another.‡——*A Subscriber.*—No.——*One of Ten Weeks.*—You will gain the information you seek from the Secretary of the Royal Agricultural Society in Hanover-square. Urine is of the greatest value; it should be mixed with twice its quantity of water, and allowed to become putrid, when it may be mixed with earth into a rich compost.——*W. C.*—You may cut hurdle coppices up to the end of April. The best Willow for planting in such places is the Bedford.——*Northumbriensis.*—As the Deodar is a Mountain plant, it is to be presumed that it will stand high winds as well as *any evergreen.* Dr. Royle says it is sometimes 10 ft. in diameter. Willow and Poplar form the purest charcoal.——*John Foster.*—You may kill blackbirds by common rat-traps, baited with anything they like. Probably jackdaws and thrushes may be killed in the same way.——*A Subscriber.*—West Indian Agriculture cannot be advantageously dealt with except by a person who has visited the islands. It is a pity that the planters do not send out a scientific commission, which, if well selected, would be the making of them. To *speculate* on such matters might do harm. We agree with you that there *is* some room for fearing that misdirected zeal may do harm. At the same time we do not see why stirring the ground should be disadvantageous. Ratooning might, we presume, be dealt with like the stools in a nursery-ground. What the Cane-fields want is plenty of strong manure, and a thorough breaking up of the land.

SEEDLING FLORISTS' FLOWERS.

CINERARIAS.—*J. S. J.*—Your seedling named No. 1, Blue Beard, is a very beautiful variety; the colour is a splendid blue, the flowers large and showy, a decided acquisition. No. 2, Bonny Bess, is sweet in colour, but it differs but little from many that are out.——*W. G.*—There is a pleasing variety in the colours of your seedlings, but the petals appear to want substance, and the flowers are very small. No. 3 is the most novel in colour, and No. 5 is prettily marked, but they both want size, and in all the petals are too narrow.——*F. B. Y.*—Two flowers of the largest Cineraria we have seen, measuring two inches in diameter; the flower is white, slightly tipped with a purple tinge; petals stout and well formed.*

*** As usual, many communications have been received too l t.

A VACANCY exists for a young Gentleman with a respectable Farmer and Grazier, in Lincolnshire, occupying extensively various descriptions of land.—Direct to X. Y., care of Messrs. Brooke, Lincoln.

ON SALE.

RED AND WHITE CLOVER-SEEDS, TREFOIL, PARSLEY, ITALIAN and DWARF RYE-GRASSES. English and Foreign LINSEED CAKE.

JOHN. QUESTON & SONS.

Office, 47, Queen-street, Hull (adjoining the Victoria Hotel.)

THE following are useful remarks upon an important subject. They are extracted from a periodical published in 1798*, which was edited by Dr. Anderson, of Edinburgh:—

"Mr. Locke began his 'Essay on the Human Understanding' by showing the necessity of adverting to the precise meanings of words. The same thing ought to be done respecting Agriculture; for we shall find that the frequent use of words and phrases which have no precise and definite meaning affixed to them has been one of the most powerful causes of that retardment which has so justly excited our wonder. To give an example: every person who has but begun to enter upon the study of Agriculture has heard of three or four grand divisions of soils, viz., clays, sands, loams, and gravels; and to each of these terms he annexes an appropriated idea, which particularly corresponds with the qualities of such soils as have been denominated clays, sands, loams, and gravels, in his native place; so that, whenever a soil of any of these denominations occurs to him, whether in conversation or in writing, he thinks it must be somewhat similar in its nature and qualities to the soils which he has been accustomed to discriminate by those names; but as the clays of one region are extremely different from the clays of another region, some of the soils so called being endowed with almost inexhaustible fertility, while others are as justly characterised by that of insuperable sterility; and as there are innumerable shades between these two extremes—as it also happens that there is a diversity equally great in regard to every other peculiarity of clay as that which respects its vegetative power, it must follow that whenever a clayey soil is mentioned among any number of farmers, that single word must convey to each of them a separate idea." Dr. Anderson then proceeds to show that the benefit which other sciences derive from the arts of writing and printing, by the accumulation through these means of the observations and discoveries of many generations, is comparatively lost to Agriculture; "for so long as one man remains ignorant of the precise meaning of the words that are employed by another, he cannot benefit by the acquirements which that other shall have made." The works of his predecessors are thus in great measure useless to him, and "each individual must begin with the knowledge that his own observations furnish; nor is he able to communicate his knowledge to others, unless it be to his immediate descendants or his nearest neighbours, to whom he may point out the identical objects with which he has been conversant. And thus we can account for the fact which must have been noticed by every Agricultural observer, viz., that striking improvements in this line have always been of a local nature."

Agricultural writings of a practical kind are generally descriptive of certain operations on certain soils, and they state the results of these operations as the test of their value. Now it is evident that the usefulness of all such writings is dependent both upon the accuracy and clearness of the description given of the soil (for many operations which would benefit some soils are injurious upon others), and upon the accuracy with which the results of those operations are described. Whether it be the fault of the author, or of the means he has at his command, if the account he gives under either of these heads be not clearly conveyed to his readers, it is evident that, by acting in accordance with what they believe to be his advice, they will either suffer absolute injury, or at any rate be much disappointed in the amount of benefit they receive.

In the above quotation, Dr. Anderson refers especially to the importance of accurately describing the soil on which any operation to be detailed is to take place; but it is obvious that his remarks are demonstrative also of the importance of employing terms by which all may understand the nature and quantity of the results of such operations; for the value of an author's report of experiments depends as much upon his due attention to the latter, as it does upon the care with which he attends to the former of these particulars. In all writings of this kind, those weights and measures which are sanctioned by Act of Parliament ought alone to be referred to. The use of LOCAL WEIGHTS AND MEASURES has been productive of much confusion and uncertainty, and, like every other source of error, is often provocative of angry and useless discussions.

We have made some inquiries into the quantity of certain measures of length, surface, and solidity, which have been and are used in many districts of the kingdom, and the following information, which we have received on this subject from many kind correspondents, is published with the view of exposing the absurdity of the system. To commence with measures of length:—the perch, pole, rope, or lug, (for it bears all these names,) which is properly the fourth part of a chain, or 5½ yards long, is the ordinary unit of length employed in the measurement of various descriptions of work; as the digging of drains, cleaning out ditches, building walls, grubbing up hedges, &c. Over Ireland it is 21 feet in length; it is the same in Richmondshire, Yorkshire; near Rayleigh, Sussex; and, for certain descriptions of work near Chepstow; for other descriptions of work near Chepstow, it is 18 or 20 feet; at Truro in Cornwall, at Cardiff, at Witney in Oxfordshire, in Berwickshire, and in Fife, it is 18 feet; in East Lothian, for certain kinds of work it is 18½ feet; at Baldoon, in Wigtonshire, and at Collumpton in Devonshire, it is 20 feet in length; at Llandilo and Swansea in South Wales, and in South Lancashire it is 24 feet in length. The unit of surface employed in the measurement of digging, paring and burning, and various kinds of field-work, is generally the square of the perch in length, whatever that length may be in the various districts in which it is used. The imperial acre is 4840 square yards; the acre of South Wales is 5120 square yards; that of Ireland and of Lancashire is 7840 square yards; that of Cornwall, the same as the Scotch, is 1¼ imperial acres; the Cheshire acre is 10,240 square yards. With reference to measures of solidity:—the imperial bushel is an arbitrary measure of 8 gallons, each containing 277·274 cubic inches; the Cornish bushel and the Carlisle bushel each contains 3 imperial bushels; the bushel used about Llandilo in South Wales, in Monmouthshire and other places, contains 10 gallons; the old bushel used about Chepstow contains 10½ gallons; and, which is the most extraordinary measure ever we heard of, the old bushel used near Swansea contained rather more than 3 imperial bushels, viz. 3 stricken half-bushels, and the 6th heaped! We extract the following from Mr. C. Johnson's "Encyclopædia of Agriculture:"—"At Abingdon and Andover, a bushel contains 9 gallons; at Appleby and Penrith, a bushel of Peas, Rye, and Wheat, contains 16 gallons; of Barley, Malt, and Oats, 20 gallons. A bushel contains at Carlisle, 24 gallons; at Chester, a bushel of Wheat, &c. contains 32 gallons, and of Oats 40; at Dorchester, a bushel of Malt and Oats contains 10 gallons; at Falmouth, the bushel of stricken coals is 16 gallons; of other things 20, and usually 21; at Kingston on Thames, the bushel contains 8½ gallons; at Newbury, 9; at Wycomb and Reading, 8¾; at Stamford, 16 gallons. The Winchester bushel contained 2150·42 cubic inches. The imperial bushel is therefore to the Winchester bushel as 2218·192 to 2150·42."

In Scotland and the north of England, grain is often sold by the boll, containing so many imperial bushels. In Wigtonshire, the boll of Oats contains 12 bushels, and that of Potatoes contains 16 bushels of ¼ cwt. each; at Newcastle, Hexham, and Richmond, the boll of Wheat contains 2 bushels; at Stranraer, it contains 4 bushels, and in East Lothian, and Berwickshire it contains 6 bushels; at Hexham, the boll of Oats contains 5 bushels, and at Stranraer, it contains 12 bushels. The sack of Wheat contains in some places 3, in others 4 and 5 imperial bushels; formerly in some parts of Monmouthshire it used to be understood to weigh 336 lbs., *including the bag!* The sack of Potatoes weighs 200 lbs. in the Isle of Thanet; in East Suffolk, &c., it contains 3 heaped bushels; in many other places it contains 5 heaped bushels, and weighs 2¼ cwt.; at Collumpton, it weighs 160 lbs.; at Rayleigh, it weighs 252 lbs. In Ireland, Potatoes are sold by the barrel of 20, 24, 48, and 96 stones.

We need not continue this subject further into the various ways of selling butter, cheese, hay, wool, meat, &c. Enough has been said to prove the extreme absurdity of sanctioning in any way the use or preservation of local weights and measures; and from what has been said it may be easily inferred of Agricultural writings which adopt local terms, whether of quantity or quality,—terms signifying length, surface, and bulk, or descriptive of soils and their production—that such writings are liable to mislead rather than inform. We are glad to find that our national Agricultural Societies are about to take up this subject, and we hope that their endeavours to induce the general adoption of a uniform system of weights and measures will be attended with success.

SALT AS MANURE.

AMONGST the many manures strongly recommended to farmers, few are more highly lauded than common salt; which, it is stated, supplies to crops all that they require, being at the same time the cheapest, most effectual, and most universal of all known manures. As to the practical evidence on which such assertions are based, I will say nothing; well authenticated facts are always valuable, and we may form our own conclusions from them; the advocates of salt as a manure are, however, not satisfied with stating simple facts respecting its use, but theorise as to the probable manner in which it may act, and endeavour to prove by those theories, its excellence as a manure. Two chemical reasons are advanced to prove the value of common salt as a fertiliser. It is stated that salt fixes ammonia; and secondly, that when decomposed by ammonia, alkali is set free, which greatly increases the fertility of the soil. In the *Gardeners' Chronicle* for 1843, No. 8, I made some observations on the action of salt on carbonate of ammonia, my object being to show, that the assertion that salt was one of the best fixers of ammonia, was not supported by chemical facts; but that, on the contrary, it was highly improbable that salt could be used for that purpose, although true that under particular circumstances salt and carbonate of ammonia partially decompose each other. As the subject is again exciting a good deal of interest, I am induced to make a few further observations on the subject, more especially in respect to the second assertion, that salt, when decomposed by carbonate of ammonia, furnishes alkali to plants.

There can be no doubt that in some situations, on particular soils, and applied to particular crops, salt in moderate quantity is an excellent manure—abundant evidence of this is given in the writings of those who have studied the effects of manures; but at the same time there are many cases in which its application has done no good, and indeed sometimes produced evil effects. In many cases, no doubt, these effects were the result of too large an application of salt, whilst in others the nature of the soil was such as to render the salt of no value.

In the following observations, my object is not in any way to discourage the employment of salt, but merely to point out the questionable nature of the scientific reasons in favour of its application, which are made use of by its advocates. When very strong solutions of common salt and carbonate of ammonia are mixed at low temperatures, they slowly and imperfectly decompose each other, and a quantity of bi-carbonate of soda and muriate of ammonia are formed, whilst a portion of ammonia is set free. The bi-carbonate of soda being almost insoluble in the solution of muriate of ammonia, may be separated and obtained pure, whilst the muriate of ammonia may be obtained by evaporating the solution and separating it from undecomposed common salt, and free ammonia. If, in place of separating the two substances, a quantity of water is added, the bi-carbonate of soda dissolves, and the two salts re-decompose each other, common salt and carbonate of ammonia being formed. In the same way, if solutions of carbonate or bi-carbonate of soda be mixed with solution of muriate of ammonia, they mutually decompose each other, and form carbonate of ammonia and common salt.

It is perfectly true that very strong solutions of bi-carbonate of ammonia and common salt decompose each other, and that common carbonate of ammonia decomposes solution of salt, when carbonic acid is passed through it; but it is equally true that this only holds good when the solutions are concentrated; if dilute, no such change takes place. When salt is employed as manure it is exposed to the action of a very dilute solution of carbonate of ammonia, for dew and rain-water contain a minute quantity of that salt; under these circumstances it is not to be expected that the salt will be decomposed; and it is not reasonable to compare what takes place in strong solutions in close vessels, with what takes place in the open air with abundance of water. We can only compare the action of rain-water on salt, to the action of very dilute solution of salt and carbonate of ammonia, and such solutions do not decompose each other. Although chemical facts are certainly against the decomposition of salt by carbonate of ammonia, or the fixation of ammonia by common salt, yet this in no way diminishes the value of salt applied as manure.

* Recreations in Agriculture, Natural History, Arts, &c., by James Anderson, LL.D., &c. &c. The writings of Dr. Anderson on Agricultural subjects, though published so long ago, are still among the most valuable in the English language.

It has been assumed that salt cannot act beneficially on vegetation except it be previously decomposed, but there appears very little proof of the truth of this assertion. Even supposing it proved that salt must be decomposed, it is yet by no means impossible that this decomposition is effected after it has been absorbed by the roots of plants; on the contrary, it is very possible that such a change may take place in their organs, and more likely than that it should be effected in the soil by the carbonate of ammonia, of dew and rain. Salt mixed with soot is often praised as an excellent manure, and mentioned as affording an example of the decomposition of the former by the carbonate of ammonia contained in the latter; there is, however, no need to suppose any decomposition to have taken place to explain the beneficial effects of such a mixture. When plants are manured with ammoniacal salts they grow with increased vigour, the roots increase rapidly, a larger supply of inorganic matter is required, and if this is withheld from the plants they do not flourish. When inorganic manures are used, plants acquire increased powers of absorbing ammonia, and when manured with salts of ammonia they acquire increased powers of absorbing in organic matters; hence, the best manures are those in which both classes of substances are supplied at the same time, and hence it would be reasonable to expect that salt and soot together would produce a more powerful effect than either alone, except in soils rich in alkaline or ammoniacal salts. The mode in which manures act can only be ascertained by observing the effects which they produce on living plants, but the changes which take place in the organs of plants cannot be compared with those which are the mere effects of ordinary chemical action. The process which can effect the decomposition of carbonic acid and water in the organs of a plant, are equally able to cause the decomposition of common salt, and other inorganic compounds.—*E. Solly.*

SOME REMARKS ON DRAUGHT.

Whatever there may be of theoretical uniformity among scientific men respecting the mechanical principles to be regarded in the construction of carriages, and the manner of applying the draught powers, there is much difference of opinion among mere practical farmers on those points. For instance, some are advocates for the four-wheel waggon, and others for the Scotch cart (or one on a much smaller scale), each party giving very good reasons for their preference of one vehicle to another. Some again maintain that the teams for all wheel conveyances and ploughs ought to be yoked in single file; and others contend (and with these I concur,) that they ought to be placed two or even three abreast, when there is room enough for the purpose. But circumstances may render it judicious to adopt a system, though it may not be correct in the general abstract principle. A Norman French farmer employs a team of five or seven horses and oxen (they are generally combined) in a single row, to draw 2 tons weight it may be of farm produce, though half or a third of the number would be sufficient for the purpose on a good road, because the execrable state of his bye-lanes renders the draught severe along them; and he arranges his cattle in single file on account of the narrow breadth of those lanes. Again, no sensible man, knowing that a horse, which can carry but 2 cwts. conveniently on his back, will draw 10 cwt. with as much or more ease in a cart, would say, generally, that it would be economical to convey manures on the backs of mules or horses, or by sledges instead of carts; yet in very hilly, uneven places, or along the rough and precipitous passes which in many localities conduct to a sea-shore, loaded panniers or sacks upon the back of a horse, or a load on a sledge, may be more safely and effectively conveyed in that manner than by means of a cart. Perseverance, however, in an imperfect practice (advisable only under peculiar circumstances) is evidently absurd when the necessity for it has ceased by the change of those circumstances. The Frenchman pursues his favourite mode of yoking his teams even on the finest road imaginable, though in every winding of a road there is a loss of power consequent upon it (incurred by the deviations from the true line of traction). He is *accustomed* to that method, which he acquired under very different circumstances, and will not adopt a new one, though in a case which, by its suitableness to his purpose, plainly invites its adoption. Hardened by custom, he carelessly observes the unequal and severe labour which is imposed on his shaft-horse in turning corners and crossing watercourses, and the painful pressure that the poor animal suffers from the belly-band whenever the weight is thrown backwards from its equilibrium by the prevailing system of harnessing. In Ireland, where the great improvements in the construction of roads within the last 15 or 20 years has led to the almost universal substitution of the spoke for the block-wheel, as the solid wheel was termed, and the abandonment of the back-load system, there is still a disinclination to adopt the high spoke-wheel, from a lingering regard for the form of the original wheel, which was found useful as a drag in descending hills, and in preventing the rude shocks which the horse would receive on very rough roads, from the concessions given to the lighter, and therefore more unsteady wheel. But another consideration also operated to preserve the use of the very defective block-wheel, even after the supposed necessity for employing it had been removed by the new construction of roads; namely, a penny-wise sort of economy evinced in the determination to wear out the old wheels before incurring the expense of purchasing new ones—a kind of prudence somewhat similar to that of a thrifty parent, who is unwilling to dress his hobbedyhoy son in a new long-tailed coat until he has completely worn out his jackets, notwithstanding that he has much outgrown them. There is, however, this difference between the two cases: in the latter there is a positive saving, and that without any hindrance to the boy's advancement, either in mind or body; while in the other case there is loss in the lesser quantities and weights conveyed by means of these imperfect wheels, and the greater wear and tear of the animals employed in moving them.

There is still, I apprehend, not only in Ireland, but in Great Britain generally, a deficiency in the formation, or rather in the height of cart-wheels. From frequent observation of the power of those which are used in France, which enable a very feeble horse to draw great weights, I am convinced that the average height of the cart-wheels we employ in road and farm labour ought not to be less than from five feet six inches to six feet. The wheel of the common Irish farmer rarely exceeds three feet six inches; for he is impressed with the notion that, if it were higher, the pressure would be too great on the horse when going down hill, having no knowledge of the simple contrivance of the Frenchman, who, by means of a piece of wood which can be pressed from behind by a simple sort of screw, causes a degree of friction which retards the action of the wheels, so as to relieve the horse in the descent. In a level country, there can be no doubt whatever of the mechanical advantage to be derived from a very high wheel, and still more on ascending ground; and though it often occasions difficulty to the horse on descending ground, from want of a friction-break, or the neglect of the carter to apply it, there is on the average of work a decided advantage obtained from the use of the high wheel, provided that it does not exceed the elevation which will admit of an horizontal shaft, or, still better, allow a trifling declination from the fore point to the other extremity; and, I may add, from a narrow axle, which causes a lesser friction than a wide one.

Having referred to the Continental custom of attaching the animals of draught to carts and roulages, one before the other, and being of opinion that the Scotch cart, with one horse, or two at the most, is the most efficacious vehicle for ordinary work, I may venture to advert to the reasons which have been sometimes urged in condemnation of the former mode, because, though the conclusion is practically correct, one of the chief reasons assigned against the yoking of the cattle to carriages (or ploughs) in single files, is that there is a loss of power in proportion to the distance at which they are placed from their load. I have myself erroneously concurred in that opinion. Now, in the first place, the term proportion, used in this sense, is wrong in a scientific point of view; for though the draft may increase or diminish, as the distance increases or diminishes, there may be neither proportion nor ratio in the amount of increase or decrease of both, as compared together.

The waste of power in the case I have supposed, has nothing to do with the distance. There is no ratio whatever in respect of that; the loss of power is only occasioned by a deviation from the direction in which the weight is to be moved; and in practice that deviation is continually occurring, owing to the inequalities and windings of a road. If there be two or more horses abreast, there can be no deviation from the true line of draught; still less can there be any such deviation in the case of the single-horse carts. From knowing that the mere increase of distance between the horse and his load will not diminish his powers of draught, it follows that very long traces may be very advantageously used on occasions; for instance, to effect the passage of a cart through a slough, at the entrance of a field, which has been deeply rutted from frequent traffic, it is plain that all the horses of a team, except the one in the shafts, would have greater power in drawing, if they were on firm ground within the field, than if they were labouring through the slough, along with the shaft-horse; a pull from the firm footing within, however long the distance, would give increased power. If the line of traction be preserved, all is right on the general principle.—*Martin Doyle.*

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. XI.

(*Continued from page 170.*)

Every practical farmer is so well acquainted with the value of good rotten manure, that it would be a waste of time for me to dwell upon the advantages derivable from the decomposition of vegetable matter. Sir H. Davy recommended the application of dry Straw to land, in order that plants might derive the benefit of its slow decomposition. Others have used dry bran upon the same principle. A little reflection, however, will convince the reader that such experiments must fail, and that it is better to secure the decomposition of these substances, before they are used. But some one will exclaim:—"Do you not obtain all the results of decomposition, and prevent volatilisation, by burying the straw?" The answer to this is simple and conclusive. In the decay of Straw by itself, there is no volatile matter formed, and therefore none can be lost. It is only where urine or animal matter is added to the Straw, that any appreciable amount of ammonia is formed by the decomposition.

When the crop of Corn is removed from the land, the grain, converted into flour or malt is consumed by man, and the animals around him. The Straw thrown into the yard is formed into manure by the cattle. Now Straw will not readily decompose without moisture. In the straw-yard it is mixed with rain and urine, both containing nitrogen. The Straw and dung contain little or no nitrogen, and we therefore see that the cause of decomposition is the source of volatilisation,—that the two phenomena depend upon each other. Without urine the Straw would make very indifferent manure, for the nitrogen of the urine is one of the principal sources of the azotised part of the future crop—the seed. Nothing can be more simple or true than this well-established fact. Surely, then, the grand object of the farmer should be to secure to his crops of grain as much azotised matter as possible; for upon this depends chiefly its *quantity*, the *quality*, and the *weight*. The more azotised matter within certain limits, the more Corn—is as clearly demonstrable as a problem in mathematics, or as the fact of the quantity of fat in the sheep being proportioned to the amount of oil-cake and turnips that it devours. The more Straw or carbonised matter in the manure, the more Straw in the crop, is also equally clear; for Straw by itself can never produce grain.

From the rain, then, containing ammonia, and the urine of cattle containing urea, (which by decomposition is converted into the carbonate of ammonia,) the Straw in the farm-yard receives a considerable quantity of azotised matter, but much of this is lost by volatilisation. The carbonate of ammonia is a volatile salt, and the grand object of the Agricultural Chemist is to fix it, convert it into a salt of ammonia, which is not volatile; and the sulphate or phosphate are of this character. Numerous remedies have been proposed to fix the ammonia of dunghills, and the experiment proposed by Professor Henslow, and now in progress in the county of Suffolk, will set at rest the value of one agent proposed—gypsum. But I do not think that the fixation of ammonia in the dunghill is of so much importance to the farmer, when compared with the means which he has always at hand, at little cost or trouble, of obtaining large quantities of ammonia easily fixed in the form of liquid manure or urine.

For this purpose every farm-yard must be provided with tanks of considerable size, in which the urine must be collected, and treated in a manner to be explained presently. That the urine is the only azotised source of stable-manure I do not mean to contend; for dung, straw, and rain-water, all contain nitrogen in small quantity. But the aggregate of these sources is so small when compared with that contained in the urine, that we are justified in treating of that liquid as the real and practical source of supply. If any person wishes to convince himself that urine contains much nitrogen, let him place a vessel of it aside for a fortnight, and then add sulphuric, or any other acid to it as long as effervescence continues. From the amount of acid used, it is easy to calculate the amount of carbonate of ammonia which the decomposition of the urine has formed. If this amount is estimated at half the weight of the acid, it will be near enough for ordinary purposes. Liebig has stated from theory that a pound of urine contains the elements necessary to form a pound of Grain. In an experiment which I made, I have proved the soundness of Liebig's "thought;" for, from 80 lbs. of urine, with the ammonia fixed, I obtained of produce 77½ lbs., and about 37½ lbs. of Grain to 40 lbs. of Straw. Now, every human being passes about a pound of urine in the twenty-four hours, upon the average; and it has been estimated that every adult is capable of manuring, by his urine alone, an acre of land per year! and yet how little of this is saved?

I have stated that, directly or indirectly, every human being is indebted to Agriculture for his food. It matters not whether he lives upon beef, or pork, or bread, or potatoes,—upon the whale blubber and roots of the Fuegian, or the oil and saw-dust of the Esquimaux; still we can trace the primitive organisation of the elements of animal nutrition to the vital operations of plants. Now, almost all human beings and animals, the former especially, take in more azote in their food than the waste of the body requires. If this takes place with the principal element of respiration—carbon (as is often the case), it is deposited as fat. But the excess of nitrogen is separated from the blood by that beautifully constructed organ the kidney, and thrown off in the urine. Nature intends to restore to nature all that is superabundant in her living organism. It is the negligence, or the blindness, or the indolence of man that prevents this means of increasing the produce of the soil from being taken advantage of.

Human urine is much richer in nitrogen than that of cattle—according to Liebig, as four to one. It is, consequently, four times better for the purposes of agriculture. But the urine has other ingredients of the seeds of corn besides azote. The seed contains phosphate of lime and magnesia, and the salt is found in considerable quantity in urine. The carbon for the starch in the seed is always to be obtained from the atmosphere; but the grain cannot of course be formed without the stalk and roots; and for their formation several important ingredients not found at all, or in sufficient quantity in urine, are requisite; and these are supplied to the soil either in abundance by the original rocks from the disintegration of which it was formed; or, as is most frequently the case, they are supplied by the constant application of rotten straw and dung by the farmer. What phosphate of lime and magnesia is deficient in the urine, is supplied by the dung; and the potash, sulphur, iron, and in heavy lands sometimes silica, is restored from time to time in the straw. In addition to this, the decay of straw is a constant source of humus, which is an important means of nutrition to the young or embryo plant. While, then, the straw and dung supply the above ingredients, the urine is the great and important, though much neglected source of azote; and thus each of the parts of stable manure contain and supply the plant with the appropriate food for each portion or division of parts into which the structure of the plant can be divided: for the whole plant, it is obvious a union of all its constituents is requisite.

It is quite clear that the principle which guides the feeding of animals holds good with regard to plants. If in fattening a bullock, we select that food which will

deposit fat (the oleaginous), such as oil-cake, &c., so in desiring to increase the bulk and weight of a grain of Wheat, we select for food that which will deposit azotised matter (gluten), and for this purpose we have every element we require in urine. But as a dog will die if fed only upon sugar, so will a plant if we do not supply it with a union of all the elements entering into its composition. —*C. B. Bree, Stowmarket.*

(To be continued.)

EXPERIMENTS ON THE RAISING OF TURNIPS.

[In No. 8 of the *Agricultural Gazette* we published the report of experiments by the Duke of Richmond and Dr. Manson on the influence of certain manures on the growth of Turnips. These experiments were apparently undertaken in competition for premiums offered in connection with the subject, by the Moray shire Farmers' Club. The second premium was awarded to Dr. Manson. Mr. M'William, to whom the first prize was awarded, has sent us the report of the Club, from which we extract the following account of his experiments.]

Rates per Imperial Acre.

* This lot was injured by the sand blowing in a gale.

Nos. 9 and 12.—The bones were watered with the sulphuric acid the day before being sown.

No. 7.—The sulphate of ammonia, guano, and bones, were mixed together.

No. 10.—The sulphate of ammonia used was dissolved with the liquid.

Nos. 16 and 17.—The bones and guano were dibbled in with a mixture of saw-dust.

Part of two drills of each experiment, measuring 4 perches, were topped, tailed, and carefully weighed on 13th and 14th December.

The quantity experimented on was 30 acres, 2 roods, 23 falls. The liquid manure was prepared in the same way as reported on last year;* but in place of being applied with a watering-pan, as then, it was put on with a cart, constructed on purpose, to do three drills at a time, and so as to give a uniform discharge when nearly empty as when full, which cannot be done by any common discharge-pipe. When 2 bushels of bone dust per Scotch acre, with the sulphuric acid, were applied with the full proportion of water, a portion of the mixture, equal to a half-bushel of bones, was put into the cart, and filled with water, which went over exactly quarter of a Scotch acre, the horse going at the rate of 3 miles an hour. When 4 bushels were applied with the acid to the Scotch acre, with the same proportion of water, in like manner a half-bushel was put in and filled up, which went over the quarter of an acre as before; but this had to be repeated, and gone over a second time. In order, if possible, to save this labour, several experiments were tried, with half the quantity of water; in this case the full bushel of mixture of bones and acid was put in at once, and the cart filled up with water, and went over the quarter of an acre Scotch, thus effecting a considerable saving of labour; and, as far as I can judge from the experiments, with equal effect. When the proper proportion of water to be put in the mixture is ascertained by experience, the plugs which regulate the discharge may be graduated, and a series of them made so as to regulate the quantity of mixture per acre during pleasure, the horse going at the regular and common pace, without having to do so by augmenting or lessening the quantity of water, or by making the horse go faster or slower, the latter being difficult to regulate.

Remarks with regard to the varieties of Turnips.—Laing's Swedes, part of No. 3, are decidedly superior to Gibb's in point of quality and hardiness, and, under the same treatment, much heavier. 4. Dale's Hybrid have been raised on Sheriffston for years, and properly selected, and decidedly a superior variety to the other yellow sown. 15. White Globes, Gibb's London, superior variety of Turnip to the Green Top White, which were of an inferior description—bought seed.—(*Signed*) *Geo. M'William.*

ON MINERAL AND INORGANIC MANURES.

No. XI.

By Professor Charles Sprengel.

I shall now proceed to explain some other phenomena which are observed on fields manured with marl.

It has been very often observed, that marl will not produce any effect on one sort of soil, whilst on another it will act most beneficially. This is to be ascribed to the fact that marl is not only of use to plants by the decomposition of humus, but that it really nourishes them by its constituent parts. If, for instance, a soil is deficient in magnesia, but not in all other essential parts, it will not be materially improved by marl, though rich in lime, gypsum, phosphate of lime, &c., if it does not contain magnesia; whilst the same marl, conveyed on a ground which contains plenty of magnesia but is deficient in other substances, will produce the most beneficial effect. I have found this out by too many experiments for me to doubt it for a single moment. I have seen, very often, that a marl merely composed of carbonate of lime and clay, produced at some places the best results, whilst in others it produced none; but chemical analysis always pointed out to me that any soil where it showed itself very useful, contained but very little lime, whilst that where it was useless, had already plenty of lime.

It is often the case, that a soil which has been marled some time since, contains yet a sufficient quantity of carbonate of lime, whilst its fertility has nevertheless become much impaired, although there is also no deficiency of humus. The reason is, that such soil, although not deficient in lime, does not possess enough of those other substances which had been once conveyed to it by the marl. At times it is only the gypsum or potash it is deficient in, and it is merely necessary to apply to it these substances to re-establish its former fertility, or to apply an additional dose of the marl previously used. The mineral substance in which it is especially wanting is, however, often obtained more cheaply than by a repeated application of marl. In most cases, however, a soil which, after a previous plentiful manuring with marl, exhibits signs of sterility, will be found deficient in humus, and in this case the marl which may yet be in the soil cannot produce any effect, because we have seen before, that it is especially humic acid, through the action of which lime, magnesia, alumina, iron and manganese, potash, soda and phosphate of lime, are conveyed to the plants. A soil which no longer contains any humus, is called in Germany over-marled (*ausgemergelt.*) In order to make it fertile it must be manured with substances which not only contain humus, or yield humus by their decomposition, but must also contain nitrogen, as any soil which is "out-marled" is always deficient in that substance. Dung, certainly, is best in most cases, but it may be also advisable to use along with it some vegetable-mould, as it requires a great deal of dung to supply the soil even with one-fourth per cent. of humus. At times, however, a soil, though deficient in humus, will yield (after being manured with marl) some good crops, in which case it may be that the marl contains some humic particles, or saltpetre, by which latter substance the plants are supplied with that essential food for them—nitrogen.

At times marl acts the first year very powerfully, but the effect soon decreases, which will be the case if it is applied in a powdery state. It is clear that in this case the particles of lime more easily become mixed with the soil, and bring the humus sooner to a state of decomposition, and many of its other constituent parts are easier soluble in water, and can be more speedily conveyed to the roots of the plants. If, on the contrary, marl is hard or stony, it will hardly act at all for the first year or two, for the lumps will not affect the humus, neither can the water penetrate into them to receive their soluble parts. At times marl will act the first year with astonishing power, and cease altogether the second; it may then be taken for granted that it contains saltpetre, which, on account of its great solubility in water, comes soon into play, and forces the plants by its great amount of nitrogen. Marl will always act better on wet soils than on dry ones,* which is chiefly caused by the plants being only able to receive nourishment through the medium of water. If, therefore, a dry soil has been manured with marl, it is always advisable to have it fallowed by Rye, as then the moisture of the winter season will remain longer in the soil. This moisture will be instrumental in the decomposition of the coal of humus and the vegetable matter, which will increase the action of the marl. On account of the necessity of preserving moisture, it is also well to let a soil manured with marl rest for a few years after the Rye has been cut down; the field may be planted with Clover and Grasses, and used as a pasture.

(To be continued.)

* To 1 bushel of bone dust sifted out, put 29 lbs. sulphuric acid previously diluted with 56 lbs. of water; and having stood 24 hours, it was then mixed up with the full quantity of water.

Home Correspondence.

Salt as a fixer of Ammonia.—An article appeared in No. 3 of the "Agricultural Gazette," under this head, signed "Peter Mackenzie," in which it is asked if any other means of decomposing common salt for the use of land have been discovered besides that of first converting into sulphate, and then into carbonate, as described in "Rural Chemistry." I am in a situation to answer this question, and I deem it of no small importance to the farmer. I saw in my newspaper last week a recommendation to apply salt to the dunghill, stating that the carbonate of ammonia generated there would be prevented from going off into the atmosphere, if common salt were occasionally thrown on the dung, as the carbonate of ammonia and common salt would by the moisture and heat of the dunghill decompose each other, forming muriate of ammonia and carbonate of soda. Carbonate of ammonia will be evaporated into the air by the ordinary heat of a dunghill, but muriate of ammonia will not—thus we not only save the ammonia, which is the most valuable part of the manure, but we get a new ingredient—carbonate of soda, which is also highly valuable. This is all to be accomplished by buying a little Agricultural salt and applying it to the dunghill—that is to say, if the foregoing be true. On reading this I got a chemist to try the experiment, and stood by him the whole time. He saturated a solution of common salt, say ½ or ¾ of a pint, put into a white glass bottle with a wide mouth and glass stopper; he then put into this strong brine several pieces of carbonate of ammonia in lumps, so that in the event of a precipitate before the ammonia was all dissolved it should be distinctly known. After shaking the bottle for half an hour so as to dissolve some of the ammonia, it was subjected to a gentle heat, and a large deposit of white powder was the result. In this state the bottle remained all night, and next morning the powder was separated from the fluid by filtration, and it was found to be soda, and the chemist said that it was mostly in a state of bicarbonate. After the powder was dried it was tested, and found to contain 29.41 per cent. of real soda, which the chemist told me proved that it contained upwards of 80 per cent. of bicarbonate of soda. Now I know all this to be true, for I saw the whole operation, and the bottle was in my own keeping during the whole period. I have directed my people to put about 1 lb. of salt to every good wheelbarrow-full of manure that they take from the stable or feeding-stalls. The adoption of this quantity is all guess-work, and if any of your readers have any experience or information on this point, I should be glad to see it transmitted to your columns. I have considered the subject of the preparation of manures for some years past; and with this new, and, to my mind, very important fact before me, I am strongly of opinion that all newly-made manure should be accumulated under a shed, with a tank to receive the drainings, salt being intimately mixed with it, but not in too great quantity;—be sure to mind this; 1 lb. to a barrowful may be too much—this can only be known by trial. Let the drainings be pumped over the dung from time to time, and the heat of the dunghill will evaporate the watery part of the fluid, and leave all the rich salts of the urine of the animals incorporated with the dung, to be acted upon by the salt as hereinbefore described."—*J. F.*

Dibbling Turnip-Seed.—This is much practised here, and by some of our very best farmers, and we believe it to be the surest way of procuring a regular braird. One sturdy Scot with an improved hand-dibble, will go over one imperial acre in a day. He makes the holes at the proper distances; a boy or woman follows with bones, or other portable manure, puts into each hole the requisite quantity, when another boy or woman follows with the seed. They take a pinch betwixt the finger and thumb, and with finger and thumb thus joined, they shove a little of the soil above the manure, and while doing so they drop the seed. By this mode you will never see a failure; and, after a little practice, the workmen become so accurate, that they scarcely ever err in giving either too much or too little of seed or manure. Perhaps this method will not do so well with guano, but for bones it is excellent, and not expensive. This hasty notice is given

* By "dry soils" are probably meant thin stony land, easily scorched in summer.

from having seen the matter hinted at in the *Gazette*.—*W. Drummond & Son, Stirling.*

Bones.—In the *Agricultural Gazette* of the 13th ult., I observe some remarks, under the signature "E. R., Halifax," with details of a conversation on the subject of that manure with a Roxburgh farmer, from which it is inferred that unboiled are preferable to boiled bones. For years back I have been in the habit of using bones largely, and have made trial of both sorts of bones. The result of my experience is, that boiled are infinitely preferable to unboiled bones. The boiled bones I made use of were procured from a large establishment in Aberdeen for the manufacture of soups for exportation, and had been subjected to a thorough boiling. I obtained them whole, and had them ground for myself. The first season I tried them to the extent of 1 ton, and at the rate of 18 bushels per imperial acre; and to test them thoroughly, I applied, beside them, in the same field, and at the same rate per acre, a ton of unboiled bones. The result proved the superiority of the boiled, as I had double the crop of Turnips from them that I had from the other. The two following seasons I increased my supply of boiled bones from 1 to 7 tons; and, had I not found guano a less expensive and equally effective manure, would have given up using any other extraneous manure than boiled bones. Last year I believe these bones were all purchased by the Duke of Richmond's land-steward for Gordon Castle, and it might be desirable to learn the result of his experiments with them. The "hoar-frost" appearance mentioned by the Roxburgh Farmer is no criterion of boiled or unboiled bones. Any one using bones is aware that they are materially affected by the nature of the soil they are used in, and the state of the weather. Here, however, the boiled bones have again the advantage, for they are not to be found entire when the ground is ploughed after Turnip in the ensuing spring, as the unboiled are, being much more easily decomposed. To produce "hoar-frost" in the drill rapidly, however, and at the same time to encourage quick germination of the Turnip-seed, let a little water be added to the bones about 24 hours previous to their being put in the ground, so as to induce a heat, which will materially assist their decomposition, and consequently rapid incorporation with the soil. I ought to mention that these boiled bones were about 12 lbs. per bushel heavier than the unboiled, and, on being heated, gave out a very strong ammoniacal odour.—*A. H., Aberdeenshire.*

Bones.—In your *Gazette* of the 13th inst., Mr. Patrick Clay, Berwick, states that for the last three or four years he has sold large quantities of bones in the counties of Roxburgh and Berwick, and that consequently I have been misinformed as to their going out of use. This I do not altogether admit: it is quite possible that Mr. Clay may have sold large quantities of bones in the two counties; it is also equally possible that in some districts they may be in less repute; my informant merely spoke of his neighbourhood, which is Kelso. My object in making the communication to the *Gazette* of the 13th ult., was to elicit information as to the respective merits of boiled and unboiled bones, and not to bring them into disrepute. If Mr. Clay can give any information on the subject, I have no doubt it will be acceptable to many.—*E. R., Halifax.*

Gorse.—Under the word Gorse in "Withering's Botany," it is mentioned, on the authority of Dr. Evans's tour in Wales, that my father, Mr. Davies, of Llechdwnny, fed a large team of horses on the young shoots of that plant. The fact is, that my father planted 10 acres of very steep land with Gorse seed, and it was cut down and ground in a mill erected for the purpose, the horses invariably preferring it to the best Hay. Dr. Evans was in Carmarthenshire, I believe, in 1802, and it had been the custom then to use the Gorse from time immemorial. One circumstance I must mention:—and Messrs. Rowland and Son ought to know it:—immediately after its use the horses' beards and moustaches grew to an enormous size. —*F. Davies.*

Lime and Salt.—I tried this mixture on two acres of old Grass land, having mixed them in the proportions recommended by Mr. Cuthbert Johnson. A heap was made, and the lime and salt were laid in alternate beds, then mixed up together, and well covered over with soil and sods. After three months this was applied to the meadow in question; it was in a state resembling mortar, and was with difficulty spread; after it became dry, it was beat to pieces, and spread and bush-harrowed. In many parts of the field the Grass appeared as if it was scorched. It did not grow luxuriantly, and the crop was the worst I ever had—in some parts not worth cutting.—*Northumbriensis.* [Possibly too much was applied.]

Analysis of Soils.—The following is a method of analysing soils for ordinary Agricultural purposes:—Weigh a convenient quantity of the earth to be analysed, say 1000 grains dried in the open air; dry the same before a fire on paper, so as not to scorch the paper; re-weigh, and the difference will be the moisture. Roast the residue; re-weigh, and the difference will be the organic matter. Pour a convenient quantity of muriatic acid on the remainder; when stirred and settled pour it off, and add oxalate of ammonia: the precipitate will be the lime. Mix remainder with water, and stir it well; when a little settled, pour off the turbid mixture, and the suspended contents are argillaceous, and the deposit siliceous.—*An Old Subscriber.*

Mangel Wurzel.—It is to be hoped the *Agricultural Gazette* will not patronise the barbarous mode often adopted of spelling this name "Mangold Wurtzel." We allow sailors to transmogrify foreign proper names into words to which they can attach some meaning, and to call the *Ville de Milan* the *Wheel-em-along*, the *Bellerophon* the *Belly-ruffian*, and to distort the beautiful Italian *Livorno* (for they no doubt have first done it) into *Leghorn*; but surely it cannot be necessary that the enlightened Agriculturists of the present day should frame the word Mangel into Man and gold before adopting it. The original and proper German name Mangel Wurzel literally means Want (or Scarcity) root, from its having been found so valuable when there was a deficiency of other food for cattle. And why should we not keep to this correct name, which is intelligible to nearly all the rest of Europe, instead of corrupting it into another which must puzzle them, and is in itself absurd?—*S.* [If our correspondent will examine a German dictionary, he will find that the words "*Beetroot*" are translated there "*Mangold Wurtzel.*" It is possible that "*Mangold*" has had its origin in Germany by some such distortion of "*Mangel*" as those quoted above; if so, the distortion is not chargeable on us. In importing an article from another country, we must just give it the name which it bears there, however ridiculous its origin may have been. The adoption of the word *Mangel* involves, we think, a very questionable theory.]

On the Preservation of Guano.—Guano has been found to exercise wonderful powers in exciting the growth of vegetable life, on nearly every kind of soil, but it is expensive in the first outlay, and to a certain extent it loses its properties by exposure to air and moisture. A few words, therefore, on the means of better preserving it will be useful to such of your readers as use it, and also to those parties who have to keep a large stock on hand for sale. It is well known that this article comes from a climate where it is nearly always dry; it is also known that a great portion of it is soluble in water—a portion containing some of its most fertilising ingredients; hence it must be evident that the exposure to continued moisture, which it receives in England, must wash out the greater part, if not the whole of the soluble matter contained in it, and render it comparatively worthless. It is probably on this account that some parties who have used this manure have found very little benefit from it, and have exclaimed against the new-fangled manures as useless, whereas it has not been the fault of the manure itself, but of the way in which it has been kept—not preserved. In order to keep guano fit for use, it must be preserved in a perfectly dry place, otherwise much useful matter will be washed out. Besides its soluble ingredients, there exists in guano a volatile compound of ammonia, to which it owes its peculiar pungent odour when in a fresh state. Old guano does not possess this pungency in an equal degree, and when very old not at all. The carbonate of ammonia, or common smelling salts of the shops, is the state in which the volatile part of the ammonia exists in this manure. By exposure to the air, even when dry, this compound escapes in the state of vapour, and when wet, is washed out; so that in course of time it is completely lost in either way. Now, as it is well known from the recent researches of Liebig, that ammonia has a wonderful fertilising power, every care ought to be taken to preserve the whole of this compound for the use of the plant, and this can only be accomplished by converting it into a fixed ammoniacal compound, which can be readily and cheaply done by the addition of about 30 lbs. of sulphuric acid (oil of vitriol), mixed with about twice its weight of water, to one ton of guano. A small excess of the acid will not be injurious, as it renders the phosphates soluble, which are not so in simple water, thus enabling them to enter by absorption into the rootlets of any plants to which they might be applied. From the remarks made, it appears that but two very simple conditions are requisite for the preservation of guano, for any length of time, in a state fit for use: the one condition being absence of moisture; the other, the addition of a small quantity of sulphuric acid.—*John Mitchell.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A Weekly Council was held at the Society's House in Hanover-square, on Wednesday last, the 20th of March; present, T. Raymond Baker, Esq., in the Chair; W. R. Browne, Esq.; F. Burke, Esq.; F. C. Cherry, Esq.; E. D. Davenport, Esq.; J. Dean, Esq.; C. G. Dupre, Esq., M.P.; A. E. Fuller, Esq., M.P.; H. Gibbs, Esq.; B. Gibbs, Esq.; Rev. C. E. Keene; W. Miles, Esq., M.P.; H. Price, Esq.; Prof. Sewell, and R. Trench, Esq. The following gentlemen were elected Members of the Society:—

Pearse, Henry, 9, Manchester Square, London.
Parke, Charles, Jun., Lower Henbury, Wimborne, Dorset.
Croft, Rev. Richard, Rector of North Ockendon, Romford, Essex.
Eve, William, North Ockendon, Romford, Essex.
Coape, William, Duddington, Stamford, Linc.
Benson, Alan, Papcastle, Cockermouth, Cumberland.
Rees, William, Treharne, Holly House, Newport, Monmouthshire.
Paris, Thomas Greenwood, Barnet, Herts.
Twitchen, Andrew, North Oakley, Kingsclere, Hants.
Stratton, William, Laverstock, Overton, Hants.

The names of 15 candidates for election at the next Meeting were then read.

Burnt Clay.—His Grace the Duke of Richmond having transmitted to the Council the results of Mr. Page's experience in the application of burnt clay, the communication was read to the Meeting. The report stated the length of time during which the burnt clay had been used on the farm, the mode in which it had been prepared, the quantity applied to the land, the time of year, and to what crops; concluding with the following statement of its effects:—"I have known," says Mr. Page's servant, "that in a wet cold season it beats all other manure for Turnips: of course, it keeps our stiff lands from congealing together, giving the seed more power to vegetate stronger. I never earthed any without seeing an improvement made. All I can say about it is, that it certainly answers on wet cold lands; it will increase the Barley crop 2 coombs per acre. I do not think it answers so well for Wheat as for Barley. It has been used on the farm for 20 years upon a small scale, but for the last six years very plentifully: last year, had the season allowed me, I should have burned 600 loads."

Model Experiments.—Mr. Miles, M.P., informed the Council, that Mr. Pusey, in his capacity of chairman of the Journal Committee, being desirous that as much practical matter as possible should be communicated to the Society, and under such a uniform statement of the plan adopted, as would lead to direct inferences on a comparison of the results obtained, had suggested to the Journal Committee that a prize should be given to promote that object, a proposition that had been unanimously adopted by the Committee, and of which the details would in a short time be laid before the Council, and the conditions of the prize made public. Mr. Miles was anxious to see the model experiment on the growth of Turnips, which on a former occasion had been recommended by the Council to those members of the Society who had the means and opportunity for engaging in such inquiries, repeated on an extended scale, embracing in its plan not only a trial of the different manures on a root crop, such as that of Turnips, but also on a grain crop, as, for instance, that of Barley, made on not less than an acre of ground, and weighing the produce of not less than half an acre: the trial being tested not only by the resulting weight of Turnips, but also by that of the Barley. He thought that such an experiment would be important and interesting in many points of view; and as it would be desirable that in this, as in the former model experiment, the seed should be obtained from a given and genuine source. He then gave notice that the attention of the Council having been called to the circumstance of there being at present no duly appointed seedsmen to the Society, he should move at the next Monthly Council, that Messrs. Thomas Gibbs and Co., of Halfmoon-street, Piccadilly, the parties who had always been engaged by the Society to furnish seed for the model experiment, and to test by cultivation the various samples of seeds and plants from time to time referred to them by the Council, should be officially appointed the seedsmen to the Society. The Council then adjourned to Wednesday next, the 27th inst.

Southampton Meeting.—A Meeting of the General Southampton Committee was held on Thursday last, Colonel Challoner, Vice-Chairman, in the Chair; at which the recommendations of the Committee respecting the plans for the Pavilion and Show-yards at the ensuing country Meeting in July, were finally determined upon, and ordered to be reported for confirmation to the Monthly Meeting of the Council on the 3rd of April next.

ROYAL DUBLIN SOCIETY.

At the last meeting of the Society, H. Kemmis, V.P., in the chair, it was reported from the Agricultural Committee, that Professor Dick, of Edinburgh, has kindly undertaken to come to Dublin in April, to deliver lectures on the diseases of cattle, at the approaching Show. It is also hoped that Professor Kane will deliver, on one of the days of the Cattle Show, a lecture on the relations of science to agriculture, and the practical benefits derivable from its application.

HIGHLAND AND AGRICULTURAL SOCIETY.

At the late monthly meeting of this Society, the first paper read was a Report of Experiments with Manures by Mr. Finnie of Swanston, near Edinburgh, at an elevation of 600 feet above the level of the sea. Oats, Barley, Tares, Grass, and Turnips were tried with about a dozen manures. The cost of all the fertilisers, with the exception of common salt and ammoniacal liquor, was 24*s.* per acre each, as that sum was considered a sufficiently large expenditure for any farmer to incur for such purposes. The amount of produce obtained from the ordinary state of the land was made the standard of comparison with that obtained from the use of the fertilisers. The results obtained were the following per imperial acre:—

	Gain	Loss
Oats.		
Ground Rape cake		£0 5 11½
Ammoniacal salts	£0 7 3	
Common salt	0 12 10	
Nitrate of soda and sulphate of soda	1 6 10	
Nitrate of soda	1 15 4	
Foreign guano	3 10 8	
Artificial guano	3 3 8	
Bones dissolved in sulphuric acid	0 4 2½	
Ammoniacal liquid		0 8 1½
Barley.		
Saltpetre		0 15 5
Nitrate of soda and common salt	0 8 6	
Common salt		0 6 9½
Foreign guano		0 1 2½
Artificial guano		0 19 0½
Bones dissolved in sulphuric acid		1 0 3½
Humus	0 2 1	
Ammoniacal salts	1 7 4½	
Nitrate of soda	1 9 4½	
Ground Rape cake	0 6 11½	
Tares.		
Gypsum		1 1 3½
Foreign guano		0 10 11
Artificial guano		0 13 6½
Nitrate of soda		0 5 0½
Humus		0 8 2½
Nitrate of soda and sulphate of soda	0 1 0	
Sulphate of soda		0 15 1½
Bones dissolved in sulphuric acid		1 1 4½
Ammoniacal salts	0 1 4½	
Ground Rape cake		0 13 7½

The fertilisers applied to the Turnip-crop cost 1*l.* 12*s.* per imperial acre, in addition to 12 tons of well-made farm-yard manure, the land which received no fertilisers being manured with 16 tons; so that the value of the

produce obtained from the fertilisers was set against that obtained from 4 tons of farm-yard dung.

	Gain in bulbs	Loss in bulbs
Turnips.		
Bone dust		£1 9 11½
Sulphate of soda	£0 18 8½	
Burned bones		2 1 11½
Rape dust kept over year		0 5 11½
Second quality of Rape dust	0 6 0½	
Best quality of Rape dust	2 2 1	
Inferior Linseed cake	1 10 0½	
Bones dissolved in sulphuric acid	0 16 0½	
Humus	0 11 0½	
Artificial guano	0 0 0	
Nitrate of soda		0 12 0
Ammoniacal salts	2 12 0½	
Foreign guano	2 8 1	
Grass.		
Sulphate of soda		0 0 10
Common salt	0 0 7½	
Nitrate of soda	2 16 6	
Foreign guano	1 0 10½	
Concentrated manure		0 5 7½
Ammoniacal salts	0 16 10½	
Sulphate of ammonia	1 8 5½	
Refuse saltpetre from powder-mills	3 2 5½	
Muriate of ammonia	0 13 8½	
Sulphate of magnesia		1 4 0
Saltpetre	0 11 9	
Soot, 30 bolls of 4 bush., at 1s. per boll	3 2 6	

Papers on Sheep-washing and Irrigation were then read. The last communication consisted of reports of trials made at the request of the Society by farmers in different parts of the country, of certain varieties of Wheat, which had been decided to be the best in a competition that took place in Edinburgh in 1842, and the comparison thus obtained was not only to be in respect of the recommended Wheats themselves, but also with varieties usually raised in the part of the country in which the experiments were made. The varieties of Wheat selected by the Society for the trials were white Dantzig woolly-eared, Pearl, and Chidham; and of red varieties, Belgian red and Blood red. To Mr. Dickson, near Edinburgh, was assigned the three white varieties, namely, Dantzig woolly-eared, Pearl, and Chidham; and they were compared with the following varieties: Short cluster, Chidham, Hunter's, Hopetoun, Belgian red, White Essex, and Fenton; and the results obtained from these were as follows per Scotch acre in value and quantity, viz.:—

	Bushels per acre	lbs. per Bushel	Value of Corn and Straw
Dantzig, woolly-cared	55	65	£26 4 0
Pearl ,,	47	65½	23 16 3
Chidham ,,	49	65½	23 17 11½
Short-cluster ,,	47	64½	22 4 1
Chillham ,,	52	65½	25 4 5
Hunter's ,,	48	64½	24 1 1
Hopetoun ,,	48	64½	23 5 5
Belgian Red ,,	53	64½	24 2 11
White Essex ,,	46	65½	22 19 6
Fenton ,,	57	64	26 13 0

To Mr. Ritchie, of Alloa, were also assigned the three above-named white varieties, and with them he compared Hopetoun, Hunter's, and Whittington, and the results per Scotch acre obtained by him were as follows:—

	Bushels	lbs. per Bushel	Value of Corn and Straw
Chidham ,,	38	64	£17 7 9
Pearl ,,	40	60	15 0 4
Danzig woolly-cared	37	63	15 15 10½
Hopetoun ,,	41	62	17 13 4½
Hunter's ,,	43½	64½	19 1 2
Whittington ,,	30	62	16 9 5

These two statements may be correctly compared, as they indicate the results per Scotch acre. Mr. Allan, Berkshire, conducted the experiments with the red varieties, and compared them with Hunter's, and he obtained these results per imperial acre:—

Blood Red, rather more than 34½ bush., 57 lbs. per bush.
Belgian Red ,, 35½ — 57 ,,
Hunter's, rather less than 43½ — 57½ ,,

Among the donations sent to the Society was a small packet of African guano, from Mr. James Bell, of Liverpool, obtained from the first cargo, per the Levenside, of 300 tons, that has just arrived in Scotland. The cargo, it seems, has been offered at auction, and 8*l.* 2*s.* 6*d.* per ton refused, but offered at 9*l.*, and but little had been sold at that price. Mr. Bell is of opinion that a large quantity of the manure will be imported. The Society has requested Professor Johnston to analyse this guano, and compare it with the Peruvian.

FARMERS' CLUBS.

Debenham.—The subject of artificial manures was discussed at the meeting of this club on the 2d inst. The gentleman who introduced the subject said, that last year he had tried several kinds of artificial manure to a small extent, with a view of testing their comparative fertilising qualities, and from the success he had had with some, he was induced to increase his expenditure this year to 30*l.* Last year he was of opinion he applied the different artificial manures too late (the latter part of April); this year he should commence immediately. He had tried guano, gypsum, nitrate of soda, saltpetre, and urate. Last year he top-dressed a piece of Wheat (every other ridge) with 2½ cwt. of guano per acre, at a cost of 28*s.* per acre; he had taken with the greatest care an equal quantity (by measure) of the produce where top-dressed and where not top-dressed, and having had them kept and threshed separately, he found there was an increase of eleven bushels per acre where he had applied the guano, beyond the produce of that where no guano was applied, and a proportionate increase of Straw. From a top-dressing of one cwt. of nitrate of soda applied to Wheat, alternate ridges, he had an increase of six bushels per acre, cost per acre 26*s.*; from saltpetre about the like increase—but the cost per acre more than for soda: with both soda and saltpetre there was an increase of Straw. He had applied urate at the rate of 5½ cwt. per acre, cost 28*s.* per acre, but without benefit from its use. He had also tried an experiment with the above manures on Clover last year, each at an equal cost per acre; he had sown two ridges with guano and gypsum, two with guano alone, two with gypsum alone, and two with urate alone. He had the greatest produce from the guano and gypsum;—from guano alone, good; from gypsum alone, good; from urate, not so good as from the other artificial manures. He believed the produce from the guano and gypsum was double, compared with the other part of the field where no manure whatever had been applied.—Another member stated he had had a small quantity of guano sent to him last year, with directions for sowing which he strictly complied with. He top-dressed a spot in his Turnips, which were up and fit for the hoe; it was a decided failure—indeed, the Turnips so top-dressed were the worst in the field. He had also used a small quantity on Grass land; the effects were soon visible; the Grass there soon outgrew the rest of the field, for which there was a good reason—the cattle grazing therein would not eat the grass when top-dressed with guano, it was so very rank; thinks probably too much was applied, or that it ought to have been mixed with ashes or mould; he had used nitrate of soda as a top-dressing for Grass land, which produced a visible increase.—Another member said he had used soot as a top-dressing for Wheat, and found an increase in the quantity both of Straw and Grain. He had watched an application of rape cake, burnt earth, and farm-yard manure, for Turnips; the proportion used was as follows:—rape cake one third of a ton per acre, drilled in with the seed; 90 bushels burnt earth, also drilled; and about 15 chaldrons per acre of farm-yard manure; the other part of the field was manured with pig manure, and from it the best Turnips were obtained; the next best, where the rape cake was applied; from the common farm-yard manure and burnt earth, the Turnips were about equal. He had also examined the Barley which succeeded the Turnips; the pig manure had the preference, then the rape cake, then the farm-yard manure; the burnt earth appeared there to have lost its power.—Another member said he had seen a field of Turnips where the occupier had manured with the best bullock-yard manure, which, falling short, he had finished the field with rape cake; where the rape cake was used there were two thirds more Turnips than where the bullock-yard manure was applied.—Another member said he had top-dressed part of a field of Wheat with soot, about 25 bushels per acre, from which the increase was four bushels per acre.—As but few artificial manures had been tried, and those only to a small extent, it was thought advisable by the club not to come to any resolution on the subject this evening, but from what had been stated, it was hoped many of the members would be induced to try as many of the artificial manures as convenient, both as top-dressings for Wheat, and also for Clover and Grasses, and that they would report the results of such experiments to some future meeting of the club.—*Wm. Green, Secretary.*

Collingham.—At the meeting of this Club, held the 5th March, J. S. Woolley, Esq., jun., came forward to explain his method of keeping Farmers' Accounts. The system is principally this,—he has two books, a journal and ledger; the journal is for one year, and contains 52 pages, one for each week; half of each page is occupied by a daily journal of labour, the other page is divided into three parts, one for the stock account, another for the corn account, and a third for the cash account, which is an account of all receipts and expenditure not coming under the head of labour, stock, or corn. The ledger then is divided into four parts, ruled double; the first is occupied by a common cash account, which receives the weekly receipts and expenditure in labour, stock, corn, &c., and at the end of the month is balanced and carried into the ledger, or second part of this book; the third part is appropriated to the yearly valuation, and the fourth is to be occupied by all debts due to and from the farm, such as cake and bone bills, rent and taxes, &c. The meeting was numerously attended, and the members expressed their satisfaction in the proposed plan.—*Robert M. Wright, Secretary.*

Reviews.

Report of the Judges appointed to inspect the Farms entered for the Prize and Sweepstakes proposed by the Yorkshire Agricultural Society. 1843. J. Coultas. York.

(*Continued from page* 174.)

"Godfrey Wentworth, Esq. [who received the second premium], has occupied his Woolley-park farm about 14 years. The four-course rotation of green crops, Barley, seeds, and Wheat, is here adopted; a variation being occasionally effected by the introduction of Beans or Tares on portions of land that would otherwise have been sown with pasture-grasses or Clover after the Barley-crop.

"*Turnips and Fallow Crops.*—The preparation for these commences as soon as the Corn is carried, by ploughing and harrowing the stubbles as much and as often as the weather permits—making the last ploughing deep to give the greatest exposure of the soil during the winter. The manure is led from the farm-yard in December and February; placed in a convenient and level site on a layer of earth, and protected from the air by a light covering of the same. For these crops the manure is conveyed by one-horse carts, up the centre of each third drill, as soon as the drills are formed, and care is taken to spread it equally and quickly that it may be covered in with the least exposure to wind and sun. The drills for Potatoes are 30 inches apart; for Mangel-wurzel 27 inches; Carrots and Swede Turnips 25 inches. We found all these crops extremely promising and remarkably clean. They had been sown about the 8th of May; 6 lbs. of Mangel-wurzel, 4 lbs. of white Belgium Carrot-seed, and 3 lbs. of Swedes were sown per acre; 15 carts of manure per acre, were allowed for these crops. One-half of the Swedes are carted to the farmyard for the cattle by removing six rows alternately; but to supply the drain thus made upon the land, a quarter of a pound of Linseed-cake per head is daily given to the sheep when consuming the remainder. For the white Turnips, which are all consumed upon the land, only 10 cart-loads of manure are allowed.

"*Grass Land.*—The management of this department is admirable. The average stock of Leicester sheep is 550; of short-horned cattle, 40, all of a very superior breed, and in high condition. There being 76 acres of good permanent Grass-land upon this farm, the heaviest cattle are pastured upon it, with a smaller proportion of sheep. The younger stock are principally maintained with the ewes and lambs upon the seeds. Much pains is taken to make compost on a large scale, which is applied to the Grass-land in the autumn, winter, and spring. Thistles and other weeds are carefully kept down. Nine farm-horses are kept."

This is a most extraordinary stock for a farm of 255 acres, of which 76 are permanently pasture, and 50 in Clover-seeds.

"The next farm, Mr. Newham's, of Edlington, afforded us great interest. As a tenant-farmer he is peculiarly liberal in his management, both by consuming Linseed-cake, to a great extent, and purchasing bones, as the following account, which he delivered to us, of his consumption of these articles for the last four years will show:

Year.	Tons of Oil-cake consumed.	Bushels of Bones consumed.	Cost of Bones
1839	13	1200	£157 10 0
1840	16	1100	151 5 0
1841	22	1000	125 0 0
1842	28	1000	125 0 0
4	78	4300	558 15 0
Average....	194	1075	£139 13 9

"His sheep, from the period of weaning from the ewes to the time of their sale when fat, whether on Turnips or Grass, have always a full supply of oil-cake, be the pasture good or closely eaten. His opinion is, that the extra produce of beef and mutton pays for the cake, and that he obtains the prodigious benefit of the superior manure without cost. Certainly the land gains much by the application of linseed-cake, as food for cattle, and we never met with an instance where so much was consumed on a farm of scarcely 300 acres.

"This year, two acres of Lucerne and two acres of Sainfoin, have been sown close to the farmstead, for the purpose of soiling. Ten regular draught-horses are employed; the practice is to purchase annually two, of two years old, and sell out two of seven years old, thus keeping the stock always young. The ewes kept on the farm, on the average of the three last years, have been 122; lambs bred from them, 151, which are sold fat, when shearlings; and in addition to this stock, from 250 to 300 shearlings are bought each September, put upon Turnips, and sold fat in the spring. Mr. Newham also fattens about 20 bullocks every winter in the yards with linseed cake, holding besides about 20 cattle of various ages. It is chiefly from the vast supply of first-rate manure, made from these causes, and the liberal purchase of bones, that the high condition of Mr. Newham's farm has been obtained. He adopts the four-course of Turnips, Corn, Clover, and Corn, varying the Corn crops, but often taking two crops of Wheat in a course, and sometimes substituting Beans in the place of red Clover. His mixture for one year's pasture is ten pounds of white Clover, ten pounds of Trefoil, four pounds of Rib-grass, four pounds of Parsley, and a quarter of a peck of Rye-grass per acre.

"Mr. Snowden, of Marr, who has occupied his farm 15 years, has also practised a course of cropping somewhat similar to that followed by Mr. Newham. He sows Swedes 22 inches apart, allowing nine carts of well-rotten farm-yard manure per acre for the rows, on which he also drills 10 bushels of bones, 6 bushels of pigeon-manure, 8 gallons of whale-blubber, and 10 bushels of ashes, all mixed together. Estimating the farm manure at 10*s.* a cart, the cost of manure per acre for the Swedes is about 6*l.* More than half this crop is carted to the farm-yard, for cattle, and not many are eaten on the Grass-land. The white Turnips have 24 bushels of bones, and 10 bushels of ashes drilled, with two pounds of seed; these Turnips are seldom drawn."

The concluding remarks of this valuable report are well worthy the attention of Agricultural societies.

"In closing our report, we may perhaps be permitted to remark, that valuable as large Agricultural meetings for the exhibition of stock and implements are, on account of the opportunities which they afford for obtaining a knowledge of the excellences to be aimed at by the breeder and the grazier; and the improvement of machinery, which these exhibitions have mainly encouraged, yet the minute inspection of well-cultivated farms, is not less worthy the attention of the arable farmer. We are of opinion that the produce of grain would be much more than doubled, and that the profit of the cultivators would be greatly increased, if the praiseworthy examples set on the farms we inspected were generally followed. An inquiring mind is necessary to form a perfect, or even a successful farmer. The best-informed farmer would, on each of these seven farms, discern that he had something yet to learn, and would see some practice from which to improve his own."

An apology would have been necessary for extracting so large a portion of a published work, had it not been

that in thus giving circulation to its contents we are simply meeting the desire of the society to whom it belongs.

The Value of Landed Property demonstrated by Practical Deductions and Illustrations, tending especially to facilitate the valuation of estates as applicable to the purposes of Agriculture. By Layton Cooke, Esq., Land-Surveyor, chairman of the Committee of Agriculture of the Society of Arts, Manufactures, and Commerce, London. Published by the Author, 7, John-st., Adelphi, London.

We have not space at present for more than a short notice of this work, but we hope to be able *soon to direct* the attention of our readers in detail to some of the important subjects of which it treats. Mr. Cooke has had a lengthened experience as a land-surveyor; indeed, it may be seen from a perusal of this work that it was written by a practical man. Besides a detail of all the points which affect the value of land, and illustrations of the mode in which they act, it contains numerous tables, showing the amount of the influence which each exerts under given circumstances. The contents of this work were first "arranged for the author's private reference, and for the purpose of conveying to his pupils a correct idea of the principles which should regulate the practice of valuing land;" and by its publication he has made known "a rational and intelligible mode of valuing," which will promote what is much to be desired—uniformity in practice.

Miscellaneous.

Rotation of Crops for Heavy Clays.—My course of crops is as follows, viz., one-fourth Wheat; after that Oats, one-half of which is sown alternately with Clover; after that, sown with Winter Tares, eaten off green by fatting sheep; then a bastard fallow for Wheat—the other half fallowed for Turnips, part eaten on the land and part drawn off; then fallowed for Spring Tares or Colesced, eaten off by fatting sheep; then ready for Wheat again. For example, say if the farm be 200 acres of arable land—

50	acres	Wheat
50	,,	Oats
25	,,	Winter Tares
25	,,	Fallow for Turnips
25	,,	Clover
25	,,	Colesced and Tares
200	acres	

This is a system I have used for some years on strong retentive clay-soil, which I have found answer well.—*Mr. Nowlson, English Agricultural Society's Journal.*

The Highland and Agricultural Society of Scotland have fixed on Dumfries as the scene of their Show for 1845.

Ventilation of Cowhouses.—Every one knows that pure air is necessary for respiration, and that air on being used by the lungs is expelled in a deteriorated condition, and rendered unfit for being again inhaled. If, therefore, cowhouses are not properly ventilated, the air becomes foul from the respired air, as well as, perhaps, from impure exhalations, and the air so deteriorated is rendered unfit to maintain health. In the neighbourhood of large towns, too, there is another predisposing cause to disease, viz., the unnatural forcing of a cow's milk by a too liberal supply of brewer's draff. Fresh supplies of air, that the blood may be purified, are essential objects of a respiratory apparatus, and if the blood that goes to the lungs is returned to the system in the same state as it is sent, death will be the consequence, for venous blood is poison to the body. It does not often happen that imperfect ventilation produces immediate death, but it is too often the real cause of inflammation, fever, and deadly distempers.—*Correspondent of Mark Lane Express.*

Guano on Turnips and Potatoes.—Having since your meeting tried the weight of our Turnips on the different manures, I find them as here annexed, per Scotch acre:—

	Tns.	cwt.	qrs.	lbs.
1. Sowed 19th May, 30 bushels bones, produced	26	3	1	10
2. Sowed 19th May, 16 bushels bones, and 2½ cwt. guano, produced	34	52	1	14
3. Sowed 19th May, 5 cwts. guano	30	16	0	16
4. Sowed 19th May, 48 tons farm-yard manure	33	15	1	4

The above variety were all Laing's Purple-top Swede. The bones and guano came away first, and kept ahead. The soil is heavy clay: all were furrowed, drained, and limed at the rate of 50 barrels per acre. We have another field manured with 45 tons farm-yard manure per acre, which has produced 40 tons, 2 qrs., 24 lbs. The soil is a middling loam; the variety green-top Swede. The Potatoes I mentioned at your meeting were planted on the 4th and 5th of May. The six acres produced 40 tons, farm-yard manure. On the 9th and 10th of May I planted six acres with 5 cwt. guano mixed with four times the weight of coal-ashes; the drills made light, and the guano put in the bottom, and the Potatoes planted on it. The difference of crop when raised was not perceptible, both averaging 12½ tons per acre; the Potatoes mostly cups; the soil heavy clay: but all drained, subsoiled, and limed, and after two Corn crops.—*Andrew Templeton, of Ballyleidy, to the Secretary of the Holywood Agricultural Society.*—*Belfast Paper.*

Pea-straw.—At a lecture of the Rev. Mr. Sidney, at Acle, Norfolk, the rev. gentleman drew attention to the waste of Bean and Pea-straw. It was cut too late. He gave the analysis of each as to nitrogen and gluten, which showed that 74lbs. of Pea-straw, and probably of Bean-straw also, equalled in nutriment 100lbs. of common hay—a fact most important for farmers here, and well known in Scotland.

Fermentation in Manure-Heap.—When a piece of paper, moistened with spirit of salt, or muriatic acid, held over the steams arising from a dunghill, gives dense fumes, it is a certain test that decomposition is going too far; for this indicates that ammonia is not only formed, but is escaping.—*Smith's Productive Farming.*

Notices to Correspondents.

CARROT-TOPS.—*Vigil.*—They form a good feed for horses; but we have *experienced* the injury to the root that arises from thus cutting the plant.

CHURN.—*Clericus.*—Milk is said to be a solvent of zinc, and zinc vessels for holding it are therefore dangerous. The churn you mention is highly spoken of; we think it is made of tin, which is perfectly safe.

CLOACINE.—*A. W.*—You may disinfect it by the use of chloride of lime. Apply to any manufacturing chemist. Mixing with charcoal-dust will improve it, and dry it; but why wait till it is dry before mixing it with your peat? Your compost, which you may make at once for use in May, will be sufficient manuring in the quantity you propose per acre for Swedes. Good guano is more valuable, weight for weight, than night-soil.

CONCRETE TILES.—*F. C.*—The price, as you will find on making the calculation, ought to have been 13*s.* per 1000 tiles. 2560 tiles are made of one ton of lime, half a ton of black cinders, four tons of common sand, two tons of fine gravel. The two latter are ground together wet, and the other materials afterwards added. More particularly, hereafter, in the course of a series of articles on the subject.

DEEP DRILLING.—*A Surrey Subscriber* had better apply to Mr. Hornsby, of Grantham, Lincolnshire, on this subject.

DIRECTION OF DRILLS.—*Sussex Farmer.*—We drill our Wheat up and down the hill without reference to the points of the compass. If your ridges are well rounded, it is well, if the fall of the land will permit, that they should run north and south, as both sides will then get an equal share of the sun; and the drills may be either across or down the ridges, according to the degree of the fall. The same rules apply to spring Corn.

DRAINING-PLOUGH.—*D. Pugh.*—We shall be able to give you information on this subject in detail shortly.

FURZE.—*P. B. B.*—It will ultimately become dead below, and very open. The plant will spread, too, by seed. A Thornfence may be hidden by evergreens at intervals, so as to render its appearance ornamental. The sediment of rivers would be a useful top-dressing for light soils. The mud of roads is useful as an ingredient of the compost-heap; mix it with farm-yard manure.

GRASS-SEEDS.—*Graminea.*—Mr. Lawson, in his "Agriculturist's Manual," recommends for deep mossy ground per acre, intended to lie in Grass, Agrostis stolonifera, 2 lbs.; Alopecurus pratensis, 2 lbs.; Festuca duriuscula, 2 lbs.; Lolium perenne, 6 lbs.; L. Italicum, 3 lbs.; Phleum pratense, 2½ lbs.; Poa trivialis, 2½ lbs.; Trifolium repens, 6 lbs.; Lotus major, 1½ lbs.; and Rye, 1 bushel.

GUANO.—*Vigil.*—The addition of gypsum to guano *may* benefit it, and certainly *will not* injure it. It will probably make it a better top-dressing for Clover.

LINSEED FOR CALVES.—*M. P. S. T.*—Boil 1 pint in a gallon of water; you need not soak it in water first. Give your calves from 1 pint to 1 quart of the jelly daily, according to their age. Give 1 pint to horses along with their Chaff, &c., twice a day. It will not improve the milk, if given as food to cows.

LIQUID MANURE.—*W. D. W.*—40 bushels of soot are sufficient of an excellent manure for an acre. It may be advantageously applied as you propose. We apply liquid manure in a water-cart. If the land be dry, the marks of the wheels are no injury. Perhaps Mr. Booth will inform you the way in which he applies it.——*Amicus.*—Use it unadulterated in wet weather, and dilute it with, say an equal bulk of water, in dry weather. Potter's Guano is an excellent manure; you can apply it after the rate of 2 to 4 cwts. per acre.

NITRATE OF SODA.—*W. Northumbriensis.*—Decomposition, were it in the soil possible, probably would not injure it. You may apply it on newly-limed land, without chance of decomposition.

PERMANENT GRASS.—*Three Years' Subscriber.*—Mr. Lawson recommends for light land shaded with trees, Agrostis vulgaris, 1 lb.; Anthoxanthum odoratum, 1 lb.; Dactylis glomerata, 5 lbs.; Lolium perenne, 8 lbs.; Poa nemoralis, 4 lbs.; P. trivialis, 2 lbs.; Trifolium repens, 3 lbs., with an ordinary seeding of Barley.

PERMANENT PASTURE.—*J. B.*—April is the proper time to sow Grass-seeds. You can sow them safely enough with an ordinary seeding of Barley, unless your land is liable to grow much straw.

POINTS OF A MILCH COW.—*G.*—We know what you allude to, and will endeavour to obtain the pamphlet.

POTATOES.—*H. C. S.*—Mix 3 cwt. per acre of guano thoroughly with the soil before planting. It will not injure your young trees, if well mixed with the soil. We shall be glad to see your account of Prickly Comfrey.

SEEDS.—*A. B. C.*—If your field is only to remain 1 year in seeds, Italian Rye-Grass is useful, on account of its rapid growth, for filling up patches that have failed. The Yoxford Farmers' Club recommends Tares at the rate of 1 bushel an acre, to be sown when the blanks have not been noticed till spring.

SULPHURIC ACID AND BONE-DUST.—*York Subscriber.*—We doubt the propriety of drying this mixture with quicklime. Rather take ashes, charcoal-dust, &c.; and on mixing these in sufficient quantity, you can get it to pass through the drill. Please send a specimen of your guano.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, MONDAY, March 16.—Per stone of 8lbs.

Best Scots, Herefords, &c.	3*s* 8 to 4*s* 0	Best Downs & Half-breds	4*s* 2 to 4*s* 6
Best Short Horns	3 4 3 8	Best Long-woods	4 0 4 4
Second quality Beasts	3 0 3 4	Ewes and second quality	3 6 4 0
Calves	4 4 5 0	Pigs	3 8 4 4

Beasts, 3003; Sheep and Lambs, 23,320; Calves, 61; Pigs, 376.

We have to day a very large increase in the supply of Beasts. Although the weather is remarkably fine, and there is a good attendance of buyers, the quantity obliges us to submit to a reduction of prices. Not only is the number larger, but the Beasts are in much finer condition than we have noticed for some time, thus there is a very great weight of meat in market. The best and most selling Scots, &c. are making 4*s*, but very many not quite so complete are sold at 3*s* 10*d*, and Short-horns are not in ready sale at 3*s* 10*d* per 8 lbs. The supply of Sheep continues very short, and the trade steady, at fully as much money; there is a slight improvement in the best Downs, but scarcely a quotable one. There are a few Lambs in to-day, but the trade for them is very dull; a nice small Lamb is worth from 5*s* 8*d* to 6*s* per 8 lbs. Calves and Pigs are a steady trade at former rates.

FRIDAY, March 22.

The trade to-day is excessively heavy. Beef almost generally suffers a decline of nearly 2*d* per 8 lbs; only the very best selling Scots may be said to maintain Monday's quotation—they still realise about 4*s* per 8 lbs. The Sheep trade is very heavy, but the best Downs are still worth 4*s* 6*d*; other qualities are fully 2*d* per 8 lbs lower than Monday. Lamb is more in request, although it is too early and cold for any extensive dealings in that article, small Lambs of good quality are making from 5*s* 8*d* to 6*s* 4*d*. Calves are heavy, at from 4*s* to 4*s* 10*d*. The Pork trade is also very dull, but we cannot observe any alteration in prices.

Beasts, 734; Sheep and Lambs, 3800; Calves, 130; Pigs, 230.

41, West Smithfield.

HOPS, FRIDAY, March 22.

THE Hop Market remains steady at full last week's currency.

HAY.—Per Load of 36 Trusses.

SMITHFIELD, March 22.

Prime Upland Hay	70*s* to 78*s*	Clover	80*s* to 105*s*	Straw	28*s* to 30*s*
Inferior	55 65				

JAS. COOPER, Salesman.

CUMBERLAND MARKET, March 22.

Superior Meadow Hay	70*s* to 75*s*	Superior Clover	100*s* to 105*s*	Straw	30*s* to 32*s*
Inferior	60 65	Inferior	90 95		

JOSHUA BAKER, Hay Salesman.

MARK LANE, FRIDAY, MARCH 22.—A few runs of Essex and Kent Wheat remain unsold, and Monday's prices cannot be obtained by 2*s.* per qr. Free Foreign is a moderate sale at the same rates. There has been a slight inquiry for Bonded, principally Red Wheat, and a little business has been done in Rostock and Polish Odessa, f. o. b. at rather reduced prices.—Barley is dull, but not cheaper.—Peas and Beans continue the same.—Oats are flat, but there is no alteration in value.

KINGSFORD AND LAY.

COVENT GARDEN, MARCH 23.—In consequence of the weather during the week having been cold and changeable there has been little new in the Market since our last Report. It has, however, been pretty well supplied, and trade begins to get brisk. The prices of Pine Apples are nearly the same as last week; they are good in quality and sufficient for the demand. Hot-house Grapes are offered at 15*s.* per lb.; they are scarce, but Portugals are plentiful. The prices of Apples and Pears are nearly the same as are mentioned in last week's Report. Oranges and Lemons are sufficient for the demand, and are not altered in price. Chesnuts are offered at from 3*s.* to 8*s.* per peck. Nuts are plentiful. Vegetables have been pretty well supplied. Broccoli is a little reduced in price. Savoys continue to get scarce, and Brussels Sprouts are not plentiful. Greens are also beginning to get scarce. Carrots and Turnips are good and plentiful. Sea-kale is slightly reduced in price, as is likewise Asparagus; the latter is selling at from 3*s.* to 15*s.* per 100. French Beans are nearly the same as last week. We noticed some excellent Rhubarb in the market, and also a few good specimens of large well-formed Cucumbers. Frame Potatoes are offered at 3*s.* per lb.; and Strawberries are selling at 2*s.* an ounce. Among Cut Flowers were Erica Willmoreana, princeps, and rubra-calyx; Gardenia radicans and florida; Gnidia pinifolia, Acacias, Azaleas, Camellias, Pelargoniums, Cinerarias, Primulas, Fuchsias, and Roses.

FRUITS.

Pine Apple, per lb., 2*s* to 10*s*	Almonds, per peck, 6*s* to 7*s*
Grapes, Portugal, per lb. 1*s* to 2*s* 6*d*	Sweet Almonds, per lb., 2*s* 6*d* to 3*s*
Apples, dess., p. bush. 6*s* to 20*s*	Nuts, Spanish, per bushel, 15*s*
—,, Kitchen, p bus. 3*s* 6*d* to 6*s*	— Brazil, 16*s*

Horse Radish, per bundle, 1*s* to 2*s*	Chervil, per punnet, 2*d* to 3*d*
Radishes, spring, 10*d* to 1*s* 3*d* p. pun.	Salsafy, per bundle, 1*s* to 1*s* 6*d*
Carrots, p. doz. bun., 2*s* 6*d* to 5*s*	Scorzonera, per bundle, 1*s* to 1*s* 6*d*
Cucumbers, 1*s* to 4*s* 6*d* each	

POTATOES.—SOUTHWARK WATERSIDE, March 18.

In consequence of the very limited supply during the past week, the best samples have gone off readily, and every description have been eagerly sought after, and some fresh arrivals the latter part of the week brought an advanced price; at the close, the subjoined rates were fully supported. The weather continues favourable for the consumption of Potatoes, and is calculated to hasten vegetation.

MARK FOTHERGILL.

J. G. WAITE, SEEDSMAN, &c, 1 & 4, Eyre-street-hill, Hatton-garden, London, embraces the present opportunity of returning his best thanks for the very liberal support he has received, and to assure his friends that his exertions will at all times be used to deserve a continuance of that preference with which he has been so highly honoured.

J. G. W. most respectfully reminds the public that the seed time is rapidly advancing, and many of the following articles will now be in requisition.

	s.	d.
Waite's Queen of Dwarf Peas . . per quart	1	0
[A splendid new variety, growing only one foot high, producing a larger pod than any of the same habit; the seed is quite distinct from all others, and larger than any dwarf Pea in cultivation. The stock is limited to a few quarts.]

Parties wishing to buy by the bushel may have a priced Catalogue on application.

IMPORTANT TO MARKET GARDENERS.

J. G. WAITE can supply sufficient ONION SEED (any sort) to sow an acre for 1l. 10s.; he furnished many large Growers last season, and several of them had as many as 600 bushels to the acre. [illegible] experience as a grower for the London markets, recommends the above plan as the most economical.

J. G. W.'s INCOMPARABLE HARDY GREEN COLEWORT is by far the best in cultivation; it turns into heart before all others, stands the frost well, and continues in use till the Spring Cabbages come in. Time of sowing, April till July. Price 5s. per lb.

N.B.—Cash, or a respectable reference in London, is expected from unknown correspondents.

FLOWER SEEDS—36 Packets, 10s.; 18 ditto, 5s., forwarded, postage free, to any part.—Apply to Mr. JOHN BROWN, Albion Nursery, Stoke Newington, London. Any preferred species may be specified in the order. Payment by Post-office order or stamps.

J. and H. BROWN have on sale an extensive collection of the most approved Plants for greenhouses and conservatories. Parties building large or small greenhouses can be well supplied.

MANURES FOR WHEAT, &c.

POTTER'S GUANO.—Result of an Experiment on Wheat, tried near Colchester—sown Nov. 1842, reaped August 1843. POTTER'S GUANO.—Seven bushels per acre gave 54¾ bush. Grain. Daniell's Manure, 40 bush. per acre, gave 46 bush. Grain. Difference in favour of POTTER'S GUANO, 8¾ bush.

Note.—The Daniell's Manure cost 3l. POTTER'S (present price) 2l.—Works 28, Upper Fore-street, Lambeth; sold by M. FOTHERGILL, 40, Upper Thames-street.

BEAUTIFUL FLOWERS.—POTTER'S CONCENTRATED LIQUID GUANO, for Flowers, Kitchen Garden Produce, &c. Sold by appointment, by SAVORY and MOORE, Chemists to the Queen, 130, New Bond-street, and 220, Regent-street, and can be had of most respectable Chemists and Seedsmen. Price 1s. 6d. the quart bottle, with directions.

DR. LINDLEY, in the *Gardeners' Chronicle* for 1843, p. 560, says—"POTTER'S GUANO will convert your desert into a paradise." And in the Number, Feb. 10, 1844—"POTTER'S GUANO is unrivalled."—Works, 28, Upper Fore-street, Lambeth.

GUANO ON SALE BY THE IMPORTERS,
JOHN BOYD & Co.,
Wellington Chambers, London-bridge, Borough.

GUANO, PERUVIAN, &c.—The above Manures, also Potter's Guano, Nitrates of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.

Lists of Prices, with Synopsis of mode of use, on application to MARK FOTHERGILL, 40, Upper Thames-street, and 5, Railway Place, Mark-lane, London.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS,
ANTONY GIBBS AND SONS, LONDON;

And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, March 22, 1844.

PERUVIAN GUANO, of first quality, and in any quantity, direct from the Bonded Stores. Also African Guano and Nitrate of Soda.—Apply to H. ROUNTHWAITE and Co., 6, Cable-street, St. George's Crescent, Liverpool.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing a more rapid vegetation in Plants than any substance known. It may be had at Mr. LAWES' Factory, Deptford Creek, price 7s. per cwt.

Phosphate of Potash,	15s.	per cwt.
,, Soda.	12s.	,,
,, Magnesia	9s.	,,
,, Ammonia	1s.	per lb.

THE URATE of the LONDON MANURE COMPANY, 5l. per Ton. It is with the greatest satisfaction, after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By promoting a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops. The Urate may be sown broadcast, or which is preferable, by the drill, at the rate of one ton to three acres, and it is desirable it should not be placed more than two inches below the surface. As a top-dressing for Wheat the Urate has been used with great advantage. Gardeners and Florists will find it very useful for Dahlias and other roots. Full particulars and Testimonials will be forwarded on application. Genuine Peruvian Guano; Phosphate and Sulphate of Ammonia; Gypsum and every other artificial Manure.

EDWARD PURSER, Secretary, 40, New Bridge Street.

ASPHALTUM in its pure state, with all the material and instruction how to prepare, or if required, the labour performed at a moderate charge.

TOBACCO ASHES.—A few Tons of Tobacco Ashes to be Sold at 3l. per ton, convenient for land or water carriage.—Apply to J. A. HUBBARD and SON, 20, Harp-lane, Tower-street. All Letters prepaid.

CHOICE FLOWERS and PLANTS in POTS.

HUMPHREYS'S COMPOUND, applicable to all Greenhouse Plants, to Seeds, Cucumbers, &c., and to promote the germination of Seeds. Sold in bottles price 1s. 6d. each, by Messrs. THORNE, Shepton Mallet; and other leading SEEDSMEN in town and country. Wholesale Agents, DAVY, MACKMURDO, and Co., 100, Upper Thames-street, London.

TO AGRICULTURISTS.

THE Dry Material for making CAMPBELL'S CORN-PRODUCING LIQUIDS, or FERTILISING STEEPS, which have arrested the attention of Agriculturists in all parts of the United Kingdom, is now to be had in Boxes containing quantities for 5 Gallons and upwards, at the following prices:—For WHEAT, Material per Gallon ....2s. 6d.

,, OATS and GRASSES,		1 6
,, BARLEY,		2 0
,, BEANS and PEASE,		2 0
,, TURNIPS and RAPE SEED		2 6

Agents in London:—Mr. EDWARD PURSER, 40, New Bridge-st.; Messrs. GEO. GIBBS and Co., 26, Down-st., Piccadilly, and Messrs. THOMAS GIBBS and Co., Corner of Half-moon-street, Piccadilly.

TO AGRICULTURISTS.

ENGLAND INDEPENDENT OF THE WORLD FOR CORN.

THE attention of the Agricultural Interest, at this momentous crisis, is requested to the great importance of LIQUID MANURE, and the ease with which it may be appropriated, by the use of FOWLER'S PUMPS, made expressly for the purpose, either portable or fixed; Garden, Ship, and Barge Pumps; also, those for Distillers, Brewers, Soap-boilers, and Tanners, for hot and cold liquor. Pumps kept for Hire, for Excavations and Wells, Buildings heated by hot-water, for Horticulture, and every variety of manufacturing purposes. The trade supplied on advantageous terms, by BENJAMIN FOWLER, Engineer, &c., 63, Dorset street, Fleet-street, London.

AGRICULTURAL IMPROVEMENT.

SPRING WHEAT.—HUMPHREYS'S FARMERS' COMPOUND, manufactured on a *new principle*, so as to present a cheap manure of greater power, and more extensive usefulness, than the guano; and without its caustic rankness, and liability to be washed out of the soil. From its wholesome character, it is unrivalled for garden culture; and as a Top-Dressing for all Spring Crops. Per acre, for WHEAT, BARLEY, &c., with a bad soil, *Five cwt.*; with better land, *Three* or *Two*. GRASS on the average, *Two cwt.* TURNIPS, THREE or TWO. Price 12s. per cwt. Agents, DAVY, MACKMURDO, & Co., Manufacturing Chemists, 100, Upper Thames-street, London.

CHOICE FLOWERS AND PLANTS IN POTS.

HUMPHREYS'S INODOROUS SOLUBLE COMPOUND. A few grains dissolved in water, and used occasionally, are effective. For list of Agents see other Advertisement.

MOST IMPORTANT TO FARMERS AND GRAZIERS.

GIBBONS' DISINFECTING OINTMENT, a most effectual and perfect cure for Epidemic and Foot-rot in Sheep; also for Epidemic and Foul in Cows' Feet, and for the Grease and Thrush in Horses; prepared only by HENRY GIBBONS, Agricultural Chemist, Wolverhampton.

This Ointment effectually destroys the American grub on Fruit-trees. Sold by all respectable Druggists in Town and Country, in packets at 2s. 6d. each. Mr. William Bailey, Manufacturing Chemist, North Street, Wolverhampton, is appointed Sole Wholesale and Shipping Agent.

IMPORTANT TO AGRICULTURISTS AND OTHERS.

ANALYSES OF SOILS, MANURES, &c., are conducted by Mr. MITCHELL, Analytical Chemist (late of the Royal Polytechnic Institution), No. 5, Victoria Cottages, Hawley Road, Kentish Town.

A vacancy now occurs for one house or outdoor Pupil, for the study of Chemistry as applied to Agriculture. Apply as above.

LEVEL.—This Instrument, the invention of a Gentleman extensively engaged in Draining, is confidently recommended for its simplicity and cheapness; it requires only one person to use it, and gives the rise and fall in land as well as the level, and is also adapted for giving a uniform fall to drains. Each Level is packed in a case 18 inches by 3. Price, 2l. Direct to W. B. WEBSTER, Hounsdown, near Southampton.

KEENE'S PATENT MARBLE CEMENT.—This CEMENT is particularly adapted for the Walls and Floors of Conservatories and Greenhouses, being calculated, from its extreme hardness, to resist the wear incident to ordinary Plastering. For Floors it has a threefold advantage over Stone-paving: 1st, in its lightness: one inch in thickness of KEENE'S CEMENT sufficing where 2 to 3 inch flagging would be employed. Next, in its appearance, combining as it does the hardness of stone with a uniform colour and even surface free from joints; and lastly, in economy, being one-third the price of Portland paving.

The most conclusive evidence can be given of the utility of KEENE'S CEMENT for these purposes by the Patentees and Manufacturers.—JOHN BARLEY WHITE and SONS, Millbank-street, Westminster.

GREAT ECONOMY.—Much time and a great deal of labour will be saved by the use of the SUSSEX CHURN. ATTWOOD, WIMBLE, and WARNER, Manufacturers, Lewes. This Churn being made entirely of block tin, the necessary degree of temperature can be given to the cream, by placing it in a pan of cold or hot water, which ensures the butter coming in 10 or 12 minutes at all seasons of the year. The simplicity of its construction, and the facility with which it may be cleaned, are no inconsiderable advantages over those now in common use.

Sizes.	Nos. 00.	0.	1.	2.	&c.
Churn	2½ lbs.	4 lbs.	7 lbs.	14 lbs.	28 lbs. of butter.

Price with pans complete, 18s. 20s. 25s. 33s. 40s.

Delivered, carriage paid, to any part of London.

London Agents.—BENHAM, 19, Wigmore-street, Cavendish-square; LIVERMORE, 30, Oxford-street; BAILY, 71, Gracechurch-street; WRIGHT'S Range Warehouse, near the Monument.

Export Agent.—BARNES & Co., 109, Fenchurch street.

N.B.—To be seen at the Polytechnic, and Adelaide Gallery.

Observe.—The Improved Water Pail, 1s. and 5s. each.

ORNAMENTAL WIREWORK FOR THE GARDEN.
390, Oxford-street, London.

G. B. THOMPSON begs to tender his acknowledgments to the Nobility and Gentry who so kindly and liberally patronised his Manufacture of Ornamental Wirework, during the past years, and begs respectfully to remind them that with the opening season he has prepared an extensive assortment of Useful and Fancy Articles, suited to the Greenhouse and Flower-garden, and invites them to an inspection of his newly-arranged and well assorted stock of Flower-baskets, Trainers, Borders, Stands, Garden Arches, Temples, Vases, and durable Cast-iron Garden Chairs and Seats, with his well-known and generally-approved Water-pot, fitted with finely-perforated roses, suited to the varying texture of different Plants; Hothouse Engines, Syringes, Fumigating Bellows, and all other Horticultural Tools and Implements of the most novel and improved manufacture. Game and Cattle Fences in variety.

RAMS FOR RAISING WATER WITHOUT LABOUR, WHERE A FALL CAN BE OBTAINED,

FOUNTAINS of every description. Specimens of the Fountain to be seen at the above address.

Also a Ram fixed on the premises. F. ROE, 70, Strand, London.

Every kind of Garden and other Pumps, Well Engines, &c.

Dianthus superbus 0 6
" japonicus, fine scarl 0 6
Didiscus cæruleus 0 6
Erica (new from the Cape) 1 0
" Andromædiflora 1 0
Eucharidium grandiflorum, new and splendid 2 6
Fuchsia (fine mixed) 1 0
Geranium, splendid vars., mixed 1 0
Gesneria splendens 1 0
Gloxinia, fine mixed 1 0
Heartsease, selected, very choice 1 0
Ipomœa maxima alba 1 0
" rubro cærulea 1 0
Ipomœa elegans & picta 1 0
Leeana Herbertiana 1 0
Lobelia ramosus 0 6
Lupinus, new from Texas 1 0
Lychnis fulgens 1 0
Martynia fragrans 1 0
Maurandia alba 1 0
Mimulus, fine mixed 0 6
" moschatus 0 6
Penstemon gentianoides splendens 0 6
Phlox Drummondii, in many beautiful shades of colour 0 6
Do., Wood's new scarl. 2 6
Picotee, from stage flowers 1 0
Pink, from sup named vars 1 0
Do., new hybrid mountain 0 6
Polyanthus, from a splendid collection 1 0
Portulaceas, in 3 varieties 0 6
Salpiglossis, fine mixed 0 6
Salvia patens and bicolor 1 0
Schizopetalum Walkerii 0 6
Silene speciosa, new and beautiful 1 0
Stock, True Intermediate 0 6
Thunbergia, 3 varieties 0 6
Verbena, fine mixed 0 6

With all the other varieties named in the former Advertisement.

All the common varieties of Flower seeds, in 3*d.* and 4*d.* packets. A general Catalogue will be sent with every order, in which each variety will be found described, whether hardy, half hardy, or tender annuals, or perennials. Grayson's fine Giant Asparagus, 3*s.* per 100 (with printed directions for planting). Strong Seakale Plants, 10*s.* per 100. New Wiltshire Kidney Potatoes, a very early and prodigious kind, 2*s* 6*d* per peck. Martin's Early Globe Potatoes, 2*s* per peck. A choice selection of Pot Roots of the best varieties of Dahlias in cultivation, from 1*s.* 6*d.* to 2*s.* 6*d.* each. Lilium lancifolium album, 4*s.* each. Double Italian Tuberoses, 4*s* per dozen Tigridia pavonia, 3*s.* per doz. Myatt's Victoria Rhubarbs (true from the raiser), 1*s.* 3*d* each. Lancashire Gooseberries, in fine variety, 8*s.* per dozen. Grape Currants, 6*s* per dozen. Mixed Grasses for Lawns, of the very finest quality, 1*s* 6*d* per lb. Mixed Grasses for Pastures, 1*s.* per lb Selections of seeds carefully assorted and packed for all climates. Standard and Dwarf Roses in fine variety. Carnations and Picotees, all the most beautiful varieties, 1*s* 6*d.* to 2*s.* 6*d.* per pair. Yellow Picotees, 1*s.* per pair. A superior collection of Pansies, comprising all the new and approved varieties, of which priced Catalogues may be had on application. A constant supply of all the choicest kinds of Phlox, Pentstemons, Œnotheras, Delphiniums, and other favourite Herbaceous Plants will be kept during March and April. Agents for the sale of Mr. MILLER'S (of Ramsgate) new Verbenas, Petunia, Fuchsias, &c.; Mr. DAY'S (of Oxford) new Fuchsias; Mr. HALLEY'S (of Blackheath) new Fuchsias: Messrs. PAUL & SON'S Roses, &c. &c.

Metallic Wire and Labels, Garden Tools, Knives, &c. &c.

Agents for the sale of Humphreys's Compound.

HURST and M'MULLEN beg to thank their friends for the kind and encouraging patronage they have received, and to assure them that all commands shall have careful and prompt attention. Wholesale and Retail Seed Establishment, 6, Leadenhall-street. Warehouse, 19, Vine street, Minories.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.—SOUTHAMPTON MEETING.—Prize-Sheets and Regulations for the Exhibition of Stock, Implements, &c., together with the blank PRINTED FORMS OF CERTIFICATE required to be filled up by Exhibitors, and copies of the printed Programme of the Meeting, may be had on application, either personally or by letter, addressed to the Secretary, No. 12, Hanover-square, London.

Exhibitors are particularly requested to observe, that all Certificates for Implements, &c., must be sent, complete, so as to reach the Secretary on or before the FIRST OF MAY; and all Certificates for Stock on or before the First of June.

By order of the Council, JAMES HUDSON, Secretary.

London, March, 1844.

CHOICE PANSIES.

J. HENCHMAN begs to inform cultivators of the PANSY that he is now sending out healthy plants of six good seedling varieties, for 21*s.* the set. Also a few choice kinds at 15*s.* and 18*s.* per dozen.—Edmonton, March 1844.

NEW HARDY ANNUAL.

VISCARIA OCULATA—DARK-EYED VISCARIA.

T. AND J. BACKHOUSE, NURSERY AND SEEDSMEN, York, have the pleasure of offering to the Public the above new and beautiful Annual, which is figured at page 83, (No. 10), of the "Botanical Register" for 1843. The blossoms are of a bright rose-colour, with a deep crimson eye, and changing to a pale purple. It flowers very abundantly through the greater part of the summer and autumn. It is a native of Algiers, and may be sown either in the open ground in spring, or raised on pots and planted out.

Packets, 2*s.* 6*d.* each, will be sent, on the receipt of a Post-office order, postage free, to any part of the Kingdom.

WOODLANDS NURSERY, MARESFIELD, near Uckfield, Sussex.

WILLIAM WOOD AND SON have much pleasure in acquainting their numerous Patrons and Friends that they have been appointed Agents for the sale of that most invaluable article—WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, samples of which may be seen, and the composition in use, at WOOD and SON'S Nursery. Sold in bottles, with ample directions for use, pints 2*s.* 6*d.*, quarts 4*s.* 6*d.* each. Discount to the Trade.

SEEDLING FUCHSIA, CACTUS, and PANSY, HOLLYHOCK SEED, &c.—LYNCOMBE VALE NURSERY, BATH.

J. KITLEY begs to inform the Nobility, Gentry, and the Public that he has purchased of Mr. POND his unequalled SEEDLING FUCHSIA (PONDII), allowed by all who have seen it to be one of the largest and handsomest Fuchsias of the day; tube and sepals bright crimson, with darker corolla, and extremely free bloomer; fine compact habit; cannot fail to give satisfaction. 5*s.* per plant.

J. K. has a few more plants of fine SEEDLING CACTUS (SPECIOSA SUPERBA), 10*s.* 6*d.* per plant. Also, good healthy plants of his SEEDLING PANSY (LYNCOMBE VALE RIVAL). This Flower, both for shape and decision of colour, is decidedly the best light PANSY out. 3*s.* 6*d.* per plant.

J. K. can recommend his HOLLYHOCK SEED, with the greatest confidence, having taken great care to select from his best full and very double Flowers of 1843 20 distinct varieties, named to colour, which he will forward to any purchaser post-free, on the receipt of a Post-office order for 5*s.* The whole of the above are now ready to send out.—Bath, March 29, 1844.

WOODLANDS NURSERY, MARESFIELD, near Uckfield, Sussex.

NEW and SUPERB FUCHSIAS, VERBENAS, PETUNIAS, CINERARIAS, CAMELLIAS, GREENHOUSE and HERBACEOUS PLANTS, HARDY CLIMBERS, and Plants adapted for bedding.

WM. WOOD & SON beg to inform their Friends and Amateurs that a Catalogue of the above, together with a List of entirely new ROSES, is now ready, and may be had GRATIS on application.

NEW FUCHSIAS.

JOHN SMITH, NURSERYMAN, Dalston, begs to announce that he intends sending out, in May next, the following fine and showy FUCHSIAS, in strong plants, at the prices named, viz., Albion, 5*s.*; Coronet, 7*s.* 6*d.*; Coccinea pera, 5*s.*; Decora, 7*s.* 6*d.*; Expanse, 7*s.* 6*d.*; Gigantea, 10*s.* 6*d.*; Hector, 5*s.*; Incarnata, 5*s.*; Modesta, 5*s.*; Neptune, 5*s.*; Reflexa, 5*s.*; Vesta, 10*s.* 6*d.*

A Descriptive List may be had on application at the Nursery, Dalston, Middlesex. The price of the Collection, 3*l.* 13*s.* Mar. 29.

AMERICAN FOREST-SEEDS.

MESSRS. EDMUND PHILLIPS AND CO., 8, London-street, Fenchurch-street, beg to inform Seed and Nurserymen that they have a consignment of all the usual varieties of the above, which they are offering at very reduced prices, with a view to effect speedy sales. They can warrant them to be fresh and genuine, all of them having been collected this last fall by a gentleman who has been long accustomed to supply the Trade.

SEEDLING FUCHSIAS.

W. PAWLEY, of the White Hart Hotel, Bromley, Kent, begs to inform the Nobility and Gentry that he has purchased the entire Stock of three splendid Fuchsias, which he intends sending out in April next, at 10*s.* 6*d.* per plant. They are considered by competent and practical men to be the best known, and twice the size of any yet in cultivation.

QUEEN.—A large Flower, a very free bloomer, and of good habits. Colour, a delicate light Pink, and a beautiful Rosy Vermillion Corolla.

PRINCE OF WALES.—A very large bold Flower, and good substance. Colour, a bright Crimson, with an extraordinary large Violet Corolla. Magnet is also a large long Flower, good substance, habit, and a free bloomer.

To prevent disappointment, which is too often the case with new Flowers, the public are requested to come and see them before purchasing. Early orders are solicited, as the stock is limited, having broke very sparingly. A specimen of each will be open to any three Seedlings of 1843, grown from young plants, for the sum of 5*l.* To be exhibited at the West Kent Exhibition, held at Blackheath, in June next. N.B.—If accepted, notice to be given this month.—Bromley, March 29, 1844.

DAHLIAS.

J. KEYNES, FLORIST, Salisbury.—"STANDARD OF PERFECTION," (Keynes').—The finest self-coloured Dahlia in the world! gained the first class prizes at Stonehenge, Windsor, Kingston, Surrey Zoological Gardens, and Crown and Anchor, Stockwell; also the first prize specimens at Stonehenge Floricultural Society, Stockwell. "It is as round as any Dahlia in cultivation; as complete an unbroken circle as could be drawn with the compasses; and as globular in front as possible. It is symmetrical to a hair, and as double as a Ranunculus. It is so remarkable as to be instantly recognised among a thousand. Colour, deep crimson. It is the flower of the season, and must be had."—*Gardeners' Gazette*, Oct. 14. "The best-grown flower we ever saw, without exception, every requisite to meet the taste of a connoisseur being complied with; good colour, a honeycomb, regularity of growth and disposition in the leaves, and above all, as complete a rotundity of shape as if it had been cast in a mould."—*Salisbury Herald*, Sept. 2, 1843. Plants in May, 1844, 10*s.* 6*d.* "Orange Superb" (Dodd's), first-rate showflower, 10*s.* 6*d.* "The specimen sent would grace any stand."—Glenny. "Emma Noke" (Dowding's), bluish white, extra fine, indispensable to a first-rate stand, 10*s.* 6*d.* Catalogues containing all the fine old varieties and new flowers for the season may be had on application.—Salisbury, March 29, 1844.

FASTOLFF RASPBERRY.

J. T. WILLMER begs to announce to his Friends and the Public generally that he is able to supply a few hundreds of the above-named Raspberry, in strong Canes, at 40*s.* per 100, warranted to be the genuine kind, packing included, with carriage paid to London; or in less quantity, price in proportion. Fine showing sort of CARNATIONS and PICOTEES, in 12 kinds, one pair of each, 24*s.* AURICULA.—Strong Plants of showing sorts, 12 plants, in 12 sorts, including basket and packing, the selection left to J. T. W., who possesses a large healthy stock.—Sunbury Nursery, Middlesex, March 21, 1844.

NEW PETUNIAS AND VERBENAS.

J. PEARSON, NURSERYMAN, Hampstead-road, London, respectfully begs to inform the Cultivators of PETUNIAS and VERBENAS that the following SEEDLINGS will be found well worth their notice. The Petunias were exhibited at the Royal Botanic Gardens, Regent's Park, in July last, and were much admired for their fine rich colour and size of flower; they were also noticed in the *Chronicle* by Professor LINDLEY. The Verbenas flowered too late for Exhibition; they will prove equal to the description given of them; they were much approved of (and orders given) by all that have seen them in flower. Plants will be sent out the first week in April. A remittance requested from unknown correspondents.

PETUNIAS.

NE PLUS ULTRA.—Colour deep rose, large and stiff flower, habit robust. 3*s.* 6*d.*

SPECIOSISSIMA.—Fine bright crimson, large and abundant bloomer. This is an excellent variety. 3*s.* 6*d.*

FORMOSA.—Rosy lilac, with fine dark centre, flower large, habit compact. This is quite a distinct variety. 3*s.* 6*d.*

CELESTIAL.—White, with dark centre, flowers large; the same habit as P. Beauty. 3*s.* 6*d.*

SPLENDIDA.—Very rich, dark crimson; large round flower; habit excellent. 3*s.* 6*d.*

VERBENAS.

TEUCRIOIDES ATRO-SANGUINEA.—Fine blood-red, long spike of flower with white eye, foliage fine dark green; decidedly the best Verbena ever offered to the public either as a pot plant or for bedding out. 5*s.*

TEUCRIOIDES CŒLESTINA.—Rich purple, changing to a beautiful sky-blue; habit strong, with a spike of flower in the true character of the old Verbena teucrioides. 3*s.* 6*d.*

TEUCRIOIDES PRINCESS ALICE.—Delicate rose, flowers large and very fragrant. 3*s.* 6*d.*

SPECIOSISSIMA.—Rosy vermillion, with white eye; flowers large; a good trusser. This is a showy and distinct variety. 3*s.* 6*d.*

BEAUTY SUPREME.—Rosy lilac, habit strong, the flowers large and fine, very clear and constant in colour; an excellent variety. 3*s.* 6*d.*

FLORIST TO HER  MAJESTY THE QUEEN.

PETUNIA PUNCTATA.

W. MILLER refers the readers of the *Gardeners' Chronicle* to his full advertisement of this beautiful flower—just remarking that its *Strong, Dwarf habit*, and *Glossy Dark Green* foliage, contrasted with its lovely, large, spotted flowers of various colours (by far surpassing any Petunia yet out), renders it a desirable object for every greenhouse, and especially to all Exhibitors. Strong plants in April, 7*s.* 6*d.*

The following Nurserymen have ordered plants, and will be enabled to supply them true:—

Messrs. Henderson and Co., Pine-apple-place, London

LONDON AGENTS.

Messrs. Warner and Warner, 28, Cornhill
Hurst and M'Mullen, Leadenhall-street
Flanagan and Sons, Mansion House-street
Noble and Sons, Fleet-street
Mr. Kerman, Seedsman, Great Russell-street
Mr. Corstein, St. James-street, Covent Garden

*** This List will appear again in a fortnight, when all other Nurserymen and Florists' names will be added who order plants. The time will also then be stated of the sending out of the plants.

The usual trade allowance when three or more are taken at once. A remittance or reference will be expected from unknown correspondents.

W. M. cannot supply more orders for choice Fuchsias till the latter part of April.

Any person having any Canadian Hollies, the following are wanted:—Some strong white Clematis Plants in the Seed-pots, 2 or 3 years' old, and the price per 100.

Providence Nursery, Ramsgate, March 27, 1844.

NEW CAMELLIAS, FUCHSIAS, and CINERARIA.

J. HALLY, NURSERYMAN and FLORIST, Blackheath, begs to offer for sale the following SEEDLING CAMELLIAS, which have been highly approved of by all who have seen them:

PULCHELLA ROSEA.—Figured and described in the "Florists' Journal" for July last; a finely-formed delicate rose-coloured Flower, perfect in shape, rising well up in the centre. Good Plants, each, 3*l.* 3*s.*

ALBA MULTIFLORA.—Colour very pure white, with sometimes a delicate pink stripe; petals thick, cupped, and round. The chief novelty and merit of this variety consists in the abundance with which it blossoms, the flowers appearing at every joint throughout the young wood, so as when in bloom to give the plant the appearance of bearing racemes of flowers. Strong plants, 1*l.* 11*s.* 6*d.*

J. HALLY can confidently recommend the following Six SEEDLING FUCHSIAS, which he intends sending out early in April; they are all very distinct and beautiful varieties.

1. SANGUINEA.—Tube and sepals clear delicate white, with crimson corolla; of excellent close habit. This very distinct variety gained the seedling prize at the West Kent Floricultural Exhibition, Sept. 6, 1843. For its character see *Gardeners' Gazette*, Sept. 9th, in the account of the said Exhibition, described as shown by Mr. Branscombe. Price 7*s.* 6*d.*

2. FAIR HELEN.—Tube and sepals white, corolla scarlet; a very neat Flower, of good habit, exhibited at the Surrey Zoological Gardens, at the September show, and universally admired. 5*s.*

3. BOYDII.—Fine thick scarlet tube and sepals, corolla large and bright crimson; of bold habit. 5*s.*

4. WAT TYLER.—Tube and sepals very large, light rose; corolla large and scarlet. A large flower, and most abundant bloomer. 5*s.*

5. KING JOHN.—Habit of plant and colour of flower like Chandleril, but twice the strength and size. A noble variety. 5*s.*

6. MARGINATA.—Very large flower; tube and sepals scarlet, corolla (large and expanding well) crimson, having a scarlet margin round each petal. Plant of particular fine habit. 5*s.*

The above collection of Fuchsias may be had, by taking the whole, for 30*s.* The usual allowance to the trade on the above.

Also will be ready for delivery at the same time with the Fuchsias, PIPER'S "PRINCESS ROYAL" CINERARIA (not yet sent out). This beautiful variety obtained the seedling Certificate at Chiswick, and first prize at the Regent's Park last season. Price 7*s.* 6*d.* each, with the usual allowance to the trade, when four plants or more are taken.

A general Collection of Camellias, Fuchsias, Azaleas, Ericas, Cinerarias, &c. Veronica speciosa, 21*s.* each; Rosa Devoniensis, from 18*s.* per dozen.

Agents in London, Messrs. HURST and M'MULLEN, 6, Leadenhall-street.

SLOUGH NURSERY, NEAR WINDSOR,
CHOICE SELECTION OF NEW DAHLIAS, 1844.

THOMAS BROWN directs attention to his beautiful SEEDLINGS, particularly that unrivalled light flower, "LADY ST. MAUR," the superiority of which over every other of its class is too well known to need further comment. Strong and healthy plants will be ready for delivery early in May.

AURANTIA (Spary's)—Orange buff; fine form and petal. A very desirable show flower; obtained numerous prizes; 3 ft. 10s 6d

ALEXANDER (Brown's)—Maroon and crimson mottled, full and constant, centre well up, and a very useful show flower; 5 ft. 7 6

DELIGHT (Brown's)—Cream, veined and tipped with purple; petal of fine substance and high centre; very distinct to any in cultivation; 4 ft. 7 6

DESIRABLE (Brown's)—Shaded buff, quite new in colour; a good show flower; 5 ft. 7 6

LADY ST. MAUR (Brown's)—White, delicately tipped with violet purple; very deep and full, high centre, forming a beautiful outline; the petals are round, and smooth at the edge; habit of Perpetual Grand: it is decidedly the finest light flower ever offered. It attracted great admiration at Windsor, and was universally acknowledged to be the finest flower in the Exhibition; 4 to 5 ft. 10 6

NUTWITH (Brown's)—Bright crimson; a fine open-cupped petal, and a good show flower; 4 ft. 7 6

RAPHAEL (Brown's)—Dark maroon, beautifully shaded with light crimson; superior petal, of excellent form; a very novel and striking variety, and will be an acquisition to any stand; 4 ft. 10 6

REMBRANDT (Brown's)—Dark purple, very round and double, rising well in the centre, and a constant show flower. It was very successfully exhibited; 3 to 4 ft. . 10 6

EMMA NORR (Dowding's)—Blush white, good general form and centre: a good useful show flower; 4 ft. . 10 6

ESSEX BRIDE (Turville's)—Delicate peach lilac, of excellent petal and form; 5 ft. . . . (*no discount*) 10 6

LADY ANTRONUS (Spary's)—White and lilac, mottled; good form, constant, and very useful show flower; 3 ft. 10 6

NONPAREIL (Proctor's)—Ruby scarlet, of first-rate properties; extra show flower; 4 ft. . (*no discount*) 10 6

STANDARD OF PERFECTION (Keynes')—Crimson; of very superior form; 4 ft. . . . (*no discount*) 10 6

SIR J. STEWART RICHARDSON (Union)—Brown ruby, great depth, and excellent show flower; 4 ft. (*no discount*) 10 6

T. B. has also Selections of fine Carnations, Picotees, and all other Florists' Flowers, Plants, Fruit trees, Shrubs, and general Nursery Stock.

A general Catalogue of Dahlias, with a List of Superb New Pansies, to be had on application.

SPLENDID NEW SHRUBBY CALCEOLARIAS for 1844.

H. MAJOR, of Knosthorpe, near Leeds, begs to announce that he has raised 30 new varieties of Shrubby CALCEOLARIAS, which he intends to send out, for the first time, in May. They are strikingly beautiful, and of good form and size. They are selected out of upwards of 100 cut specimens which were exhibited at the Grand Annual Floricultural Show, held in the Museum Gardens, at York, Aug. 16, 1843, and had an extra prize awarded them; they also obtained an extra prize at the Leeds September Show. The following eight will be sent out together for 2*l.*:—

MIDAS.—Lemon ground, strongly marked all over the surface with red brown; good form, singularly beautiful, inch across.

FLORA.—Creamy white, densely marked on the surface with large and small spots of carmine, leaving a distinct belt round the edge, good formed flower, inch across.

APOLLO.—Lemon centre, thickly marked with large and small spots of chocolate, leaving a belt of cream round the flower, strongly marked in the throat, well-formed flower, better than an inch across.

AURORA.—Solid blotch of rich crimson brown in the centre, distinctly belted with clear yellow: round, well-formed flower, very showy, 1¼ inch across.

CYNTHIA.—Rich rosy amaranth centre, belted with light buff; fine formed flower, inch across.

MARS.—Centre mottled with two shades of red, distinctly belted with bright yellow; fine formed round flower, inch and a quarter across.

CERES.—Clean sulphur, with white shoulders; good formed bold flower, inch and an eighth across.

HERCULES.—Solid maroon centre, belted with brick red; good round well-formed flower, inch and a quarter across.

The remainder of the 30 (see Catalogue) at 3*s.* 6*d.* each.

The following approved varieties of last year may be had at 2*s.* 6*d.* each:—Purity, Enterprise, Mrs. Meynell Ingram, Knosthorpe Hero, and Bridal Ring. Other good sorts at 1*s.* each. Amateurs desirous of growing a small collection, by stating the amount they wish to expend, may depend upon having such varieties as he trusts will meet their approbation.

Mr. M. has still a few plants of his new Seedling Pansy "Princess Alice," at 5*s.* each; and he offers 24 first-rate varieties for 30*s.*, post-free. For names, see List. A few packets of very select Calceolaria and Pansy seed, 2*s.* 6*d.* per packet. A List of Select Pansies and Dahlias may be had on post-paid application. From unknown correspondents a remittance is respectfully requested.—Knosthorpe, March 28, 1844.

SHADES FOR GREENHOUSES.

J. WEEKS & Co., ARCHITECTS, Hothouse Builders, &c., Gloucester-place, Chelsea, beg to inform Horticulturists that they have made great improvements in their excellent and simple plan of Shading, whereby the largest or smallest can be instantly covered or uncovered with a sheet of canvas. To be seen in use at most of the London Nurseries, and at the Horticultural Manufactory, Gloucester-place, Chelsea, near Sloane-square.

FASTOLFF RASPBERRY.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, THE MOST NOBLE THE MARQUIS OF AILSA, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c. &c.; as well as by the HORTICULTURAL SOCIETY OF LONDON.

YOUELL AND CO. have much pleasure in announcing they are now supplying Fine Canes of the above highly-valuable and much-esteemed RASPBERRY, unequalled for the extraordinary size of its fruit and richness of flavour.

Those to whom Y. and Co. sent it last season have expressed their high admiration of its superiority over all other varieties, and has been awarded several prizes from various Horticultural Exhibitions during the season. As a proof they have not exaggerated its excellent qualities, fruit was submitted to Dr. LINDLEY, (see *Gardeners' Chronicle* of the 22d July last, page 502), whose opinion of it is as follows:—

"FASTOLFF RASPBERRY.—We have received from Messrs. YOUELL, of Great Yarmouth, fruit of the Fastolff Raspberry, and we find its merits all that has been stated in favour of its excellence. The fruit that we have received is very large, obtusely conical, and of rich flavour, far exceeding in this respect some other new and large varieties. The plants bear abundantly, and in long succession."

They also exhibited it on the 1st of August, 1843, before the London Horticultural Society, 21, Regent-street, to which a prize was awarded. It would therefore be unnecessary for YOUELL and Co. to recommend it more fully, or with greater confidence to the notice of the public, merely observing, that it continues in high perfection throughout the autumnal months, and has maintained its superiority in the most unfavourable soils and situations, and requires no other than the ordinary treatment of the old varieties.

Fine Canes are ready for delivery, and can be sent with safety to any part of the United Kingdom (on the receipt of a Post-office order), upon the following terms:—

Packages containing	100 Canes . .	£2	5*s* 0*d*
Do.	do. 50 do. . .	1	5 0
Do.	do. 25 do . .	0	14 0

Package included.

The usual discount to the Trade where not less than 200 are ordered.

*** CAUTION.—Y. and Co. beg to call the attention of their Friends and the Public in general to the fact that they have appointed no Agents in London for the sale of the above, and cannot be held responsible for its being genuine, unless purchased direct from their Nursery.

THE NEWEST AND VERY BEST FUCHSIAS, VERBENAS, PETUNIAS, ANAGALLIS, &c.
FOR 1844.

YOUELL AND Co. beg to refer the Readers of the *Gardeners' Chronicle* to their Catalogue of the above, which appeared in this Paper of the 23d of March, and will be found to contain such varieties only as are worthy of cultivation.

YOUELL & Co. being the parties who first sent out per post, with safety, these tribes of plants, are desirous of calling attention to their advantageous method of executing orders, namely, that they will deliver them free of postage (on the receipt of a Post-office order), to any part of the United Kingdom, upon the following terms:—

12 Extra Fine varieties,	12*s.*,	the Selection left to Youell & Co.
12 ditto ditto	21*s.*,	the Selection left to the Purchaser.
50 Fine varieties .	40*s*,	the Selection left to Youell & Co.
50 Extra Fine ditto .	60*s.*,	the Selection left to the Purchaser.

VERBENAS.

12 Extra fine Varieties,	6*s.*,	the Selection left to Youell & Co.
12 Ditto ,,	10*s.*,	the selection left to the purchaser.

With the exception of those marked thus *

The plants will be strong and healthy, and ready for delivery by the latter end of March, with the exception of those marked thus * (which will be ready in April), thus ensuring the Purchaser fine plants for competition in the ensuing season. Many of the varieties can be supplied now.

CHRYSANTHEMUMS.

50 Newest and Best varieties, 12*s.* per dozen.

PANSIES.

12 Fine Show Varieties, by name, 9*s.* per dozen.
12 Extra fine do. do. 10*s.* ,,

Per post free.

FLOWER-SEEDS.—30 packets of the newest and best kinds, sent per post free for 6*s.*

TWO NEW SEEDLING PICOTEES.—"LADY ALICE PEEL," 10*s.* 6*d.*, and "MRS. BENYON," 16*s.* 6*d.* per pair.—These two splendid Picotees were raised by the Rev. J. Burroughes, of Lingwood Lodge, Norfolk, and kindly presented by that gentleman to Messrs. YOUELL & Co., for particulars of which see their Advertisement in this Paper of the 16th of Sept.

FINEST CARNATIONS AND PICOTEES.

YOUELL AND Co. beg to refer the Readers of the *Gardeners' Chronicle* to their Extensive List, with Prices, of the above highly esteemed Flowers, which appeared on the Advertising pages, 706 and 707, of this Paper, of October the 14th, and will be found to contain every variety worthy of cultivation.

Prices as follows:	£.	*s.*	*d.*
12 pair of good Show Sorts	1	4	0
12 ditto fine ditto	1	10	0
25 ditto ditto	3	0	0
12 ditto extra fine and very superior ditto .	2	10	0
25 ditto ditto	5	0	0

The selection being left to YOUELL & Co.

ARAUCARIA IMBRICATA.

Recently planted most extensively at Her Majesty's Gardens at Windsor, and also at the Royal Gardens, Claremont, furnished by YOUELL and Co.

YOUELL AND Co., possessing the most extensive stock in the country of the above Splendid Hardy Ornamental Tree, beg to offer them on the following advantageous terms:—Fine robust 4-year old plants, 8 to 10 inches high, 10*l.* per 100, or 30*s.* per dozen.

Fine Plants of CEDRUS DEODARA, 2ft. to 2ft. 6 ins., 10*s.* 6*d.* each.

Great Yarmouth Nursery, March 29, 1844.

N.B. All Orders above £2 will be delivered carriage free either to London or Hull.

EXHIBITION of CAMELLIA JAPONICA, or Japan Rose.—A Collection of these beautiful Exotics is now in Bloom at CHANDLER & SONS' Nursery, Vauxhall. Admittance gratis.

S. AND J. DILLISTONE will continue to supply Scions of their APPLE, the STURMER PIPPIN, throughout April, in packets of Six Scions, upon receipt of 2*s.* 6*d.* See Advertisement in this Paper of the 16th and 23d inst.

Nurseries, Sturmer, Halstead, Essex.

N.B.—This Advertisement will not be repeated.

CARNATIONS AND PICOTEES.

JOHN SLATER, Florist, Cheetham Hill, near Manchester, has on sale upwards of 1000 pairs of healthy plants of Carnations and Picotees, which he will sell at low prices. 20 pairs of Carnations and Picotees, one pair of each variety for 20*s.*, package included, provided the selection is left to J. S.

CHOICE PANSIES.

J. FRYER begs to remind his Friends that he can now supply good healthy plants of most of the leading varieties of PANSIES, Catalogues of which will be forwarded on application; likewise packets of Seed from his superb collection, 1*s.*, 2*s.* 6*d.*, and 5*s.* each. J. F. likewise begs to say that he can supply a few more packets of his new Thunbergia Fryeri; four seeds, 2*s.* 6*d.*, eight seeds, 5*s.*, and all the new Fuchsias, Verbenas, Carnations, Picotees, and an extensive collection of Herbaceous Plants, all of which will be supplied at very moderate prices.

N.B. Agent for Potter's Guano and Humphreys's Compound.

Clarendon Nursery, Camberwell, London, March 29, 1844.

H. CORSTEN, 19 A, Davies-street, Berkeley-square, Florist to Her Majesty, has just imported a splendid Collection of Gladiolus Gandavensis, so greatly admired on the Continent. See *Gardeners' Chronicle*, Feb. 24, 1844, under Miscellanea. He has also for sale the Dutch Plum Gooseberries at 12*s.* per dozen; Dutch Grape Currant Trees, 6*s.* 6*d.* per dozen; large Orange and Lemon Trees, 10*s.* each. A choice Collection of Araucaria imbricata, and Pinus; also a splendid assortment of Scarlet and Red Rhododendrons: under the last named is the large Scarlet La Gloire d'Haarlem, 5*s.* each.

SEEDS.

THOMAS GIBBS & Co., corner of Half-Moon-street, Piccadilly, London, Seedsmen to the Hon. Boards of Agriculture of England and Sweden, beg to call the attention of Agriculturists to their general Stock of SEEDS, and they beg to assure their Friends that they have bestowed the greatest care and attention to the selection and saving of the various kinds. They beg to call particular attention to the following kinds, viz.: White Belgian Carrot, which produces the largest crops; Large Field Altringham Carrot, an excellent Field Carrot; Long Red Mangold Wurtzel, large produce on deep soils; Yellow Globe do. do., adapted to shallow soils; Red Globe do. do., adapted to lighter shallow soils; Purple Top Swedish Turnip, very fine small top; Green Top do. do, hardy and useful Turnip; Gibbs's Green Top Yellow Hybrid Turnip, highly approved; Red do. do., and other varieties. Mixtures of selected Natural Grass-Seeds, properly apportioned to suit the nature of various soils. From long experience and extensive practice in this particular department, T. G. and Co. confidently recommend their Mixtures to their Agricultural Friends. Mixtures of Grass-seed for Field-lawns; Do. for Grass Plots. Italian Rye-Grass, Improved Perennial Rye-Grass, and other kinds of Grass-Seed.

PERENNIAL GRASS SEEDS.

SUTTON AND SONS, having for many years paid particular attention to the collecting of NATURAL GRASSES, and having been employed by most of the Nobility and Gentry of Berkshire, Hampshire, and Oxfordshire, to mix Seeds in proper sorts and proportions to suit the soils on their Estates, both for laying down new Pastures and improving old ones, have great confidence in soliciting orders from the readers of the *Gardeners' Chronicle*, in the more northern parts of the kingdom.

SUTTON and SONS have just published a Descriptive Table of Grasses, with some information which they consider would be acceptable to their Agricultural friends, and which may be had gratis.—The cost of the Seeds is very moderate, as will be seen by a reference to the Table above referred to.

Agents for Potter's Guano.

Reading Seed Warehouse, 7 and 8, Market place, Reading, Berks.

AGRICULTURAL SEEDS.

WHITE BELGIUM GREEN-TOP CARROT, 1*s.* per lb.; Altringham Carrot, 1*s.* per lb.; Large Green-top Orange Carrot, very thick-shouldered, and well adapted for shallow soils, 1*s.* 6*d.* per lb.; Long Red Mangel Wurzel, grows well out of the ground, 1*s.* per lb.; Fine long Yellow Mangel, produces roots as large as the red, 1*s.* 6*d.* per lb.; Yellow Globe Mangel, 1*s.* per lb.; Lucerne, 1*s.* per lb.; Italian Rye-Grass, 8*s.* per bushel; Pasture Grasses of all kinds, fine mixed Grasses for Lawns; Skirving's Improved Swede Turnip, 1*s.* per lb.; Laing's do., 1*s.* per lb., &c. &c.—W. J. NUTTING, Seedsman, 46, Cheapside, London.

Garden and Flower Seeds of every kind, as advertised by other houses.

LONDIGES' BOTANICAL CABINET, consisting of coloured delineations of Plants from all countries, with a short account of each, 2000 plates, engraved by George Cooke, and most accurately coloured from Nature, 20 vols. small 4to, elegantly bound, Russia, gilt leaves, 1817-33, price 28*l.* Published at 50*l.*, in Numbers, and now very scarce.

WM. JOHN CORMACK, AGRICULTURAL SEEDSMAN by Appointment to His Royal Highness PRINCE ALBERT, New Cross, Surrey, and Bedford Conservatory, Covent Garden, begs to call the attention of the Nobility, Gentry, and Agriculturists in general to his combinations of GRASS SEEDS for Permanent Pasture, the Alternate Husbandry, Parks, Lawns, &c. (as recommended and practised by his partner, the late Mr. GEORGE SINCLAIR, Author of the "Hortus Gramineus Woburnensis.") Upwards of 25,000 acres have been converted to permanent pasture by this establishment with the greatest success. Parties requiring Seeds are respectfully requested to state the nature of the soils. Mangold Wurtzel, Carrot, and Turnip-seed of excellent sorts, saved from transplanted bulbs. Garden and Agricultural Seeds of the best quality and most approved kinds.

N.B.—Cormack's British Queen and Prince Albert Peas, at 3*s.* 6*d.* per quart.

TO GENTLEMEN, FLORISTS, and OTHERS.

MESSRS. PROTHEROE AND MORRIS will submit to public competition at the AUCTION MART, BARTHOLOMEW-LANE, on TUESDAY, APRIL 2d, and THURSDAY, 4th, 1844, at 12 o'clock, a fine Collection of CARNATIONS and PICOTEES, consisting of all the leading varieties; Standard and Dwarf ROSES, Fine Lancashire GOOSEBERRIES, Choice FUCHSIAS, DAHLIAS in dry roots, &c.—May be viewed the morning of sale. Catalogues may be had at the Mart, and of the Auctioneers, American Nursery, Leytonstone.

EDGING BOX.—To be disposed of, A Quantity of very fine BOX, about 400 yards, at 9*d.* per yard. To be seen by application to RICHARD TURNER, Green-lane, Battersea.

TO BRICKMAKERS, FARMERS, and OTHERS.

FOR SALE, about 1000 Chaldrons of ASHES and BREAZE, and about 1000 Loads of MANURE, lying at Albion-street, and near King's Mills, where barges may be loaded. Apply to Mr. THOS. AVERY, Albion-street, Rotherhithe, Surrey.

ELIGIBLE INVESTMENT.

TO BE SOLD, with immediate possession, a Freehold DWELLING-HOUSE, SHOP, &c., and about Six Acres of rich, productive Land, fully stocked and cropped, on which an extensive business in the Nursery and Seed line has been carried on for many years, and parted with in consequence of the death of the late Proprietor, who was in business upon the premises for 50 years, and whose books may be inspected, if desired. The House fronts the high turnpike-road, in a good market town 20 miles from London. Part of the money may remain on mortgage, if desired.—Apply to Mr. THOMAS JACKSON, Marlborough-road, Old Kent Road.

MOUNTFIELD, SUSSEX.

TO BE LET, and possession had at Michaelmas, 1844, MOUNTFIELD-PARK, and GLOTTINGHAM FARMS, containing about 500 acres of excellent Arable, Pasture, and Hop Lands.—For particulars, apply to Mr. JAS. HILDER, Robertsbridge.

W. JACKSON AND CO. beg to offer the following PLANTS, at the very low prices attached:—Trapeolum azureum, 12s. 6d. each. Also, well-established in 48-sized pots—Veronica speciosa, 21s. each; Clematis Sieboldii, 30s. per dozen; C. aurea grandiflora, 24s. per dozen. Fuchsias.—12 of the most approved distinct new varieties, including a very beautiful Seedling not yet sent out, which they warrant will give satisfaction, 30s. Delivery at the railway station gratis. A reference or remittance from unknown correspondents is respectfully solicited.
Cross Lanes Nursery, near Bedale, Yorkshire, March 25.

MESSRS. MARNOCK and MANLEY beg to inform their Friends and the Public, that their DESCRIPTIVE CATALOGUE of FUCHSIAS, VERBENAS, CINERARIAS, DAHLIAS, &c., with a Treatise on the best and most successful Modes of Cultivation, is now ready, and may be had on application.
N.B.—Their beautiful Fuchsia, MARNOCK'S PRINCESS SOPHIA, is now ready to be sent out; the stock is not large, therefore early orders will prevent disappointment.
Nursery, Hackney, March, 27, 1844.

The Gardeners' Chronicle.

SATURDAY, MARCH 30, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

MONDAY, April 1	Entomological	8 P.M.
TUESDAY, April 2	Horticultural	3 P.M.
	Linnean	8 P.M.
WEDNESDAY, April 3	Society of Arts	8 P.M.
FRIDAY, April 12	Botanical	8 P.M.

WE have now before us a goodly crop of letters upon the speculations of Mr. W. Wood as to the principles on which the *rationale* of potting is, as he supposes, dependent. When his paper on Fuchsias shall be concluded, we will endeavour to explain what we understand to be his meaning; and, at the same time, the letters of our correspondents shall be duly noticed. In the mean while, we must beg to set them right on one or two points.

Some seem to imagine, because we have directed attention to Mr. Wood's paper, that therefore we adopt his reasoning as our own. They could not have fallen into a greater error. Our own little children demand all our care, and our benevolence does not go to the extent of accepting the paternity of other people's productions. Although our observations upon the paramount importance of studying the principles of horticulture were connected with the paper on Fuchsias, we did not intend that they should be interpreted into a eulogium of the particular views promulgated by its author. It is one thing to speak with praise of the general tendency of a man's writings, and another to approve of their details. What we wished was to induce gardeners *to think*, and *for themselves*; and to accustom them to *search* for the true causes of the most common operations of their art.

Suppose Mr. Wood's notions about the properties of matter, in connexion with the art of potting, to be wholly wrong, that would not alter our opinion one iota: they are new; they are an attempt to explain on principle a very important process upon which scarcely a thought has been bestowed by science up to the present hour,—and that is enough for us. His paper is a step in the right direction; and its errors will lead to discussion and consideration, out of which the right will spring. The assertion of Democritus that the goddess Truth resided at the bottom of a well was full of wisdom. The wrong reasonings of a thinking man are like failures in experimenting—they pave the way to success hereafter. The bad physiology of Linnæus opened a road to the just views now entertained of Vegetable development; if it had not been for the false speculations of the alchemists, chemistry would have been retarded for centuries—without a Paracelsus there might not have been a Davy; the dreams of Descartes led to the philosophy of Keplar and Newton; and who shall say that the misty revelations of Mrs. Ibbetson did not herald the brilliant observations of Brown, Mirbel, and Schleiden?

Another class of correspondents protests against the obscure style of the paper on Fuchsias. But shall we throw away our corn because of the chaff that hides it? or shall we not rather sift and winnow it patiently until the valuable grains are separated, and the refuse is cast to the winds? And so it should be with the writings of man; for it may happen that the truest thoughts are concealed by the obscurest words, and that what reads smoothly and speaks instantly to the apprehension will produce an effect as fleeting as it was sudden. It is more profitable to fish for gold in muddy waters than to gaze on pebbles through a stream of crystal. Not that we are advocates of a perplexed and confused style, which is a real misfortune to both reader and author; but we would not, on that account, discourage the endeavours of untaught men. On the contrary, we regard it as one of our most important duties to employ the power which education has conferred upon us in assisting others to whom Providence has not given the same advantages. We confidently trust that our readers will think that we are right.

FUCHSIAS.

(Continued from page 170.)

Some may wonder at my recommending plants to be retained in the pots supposed to have a defective arrangement of soil; it will therefore be as well that I should offer reasons for the recommendation; which is founded upon the principle (page 20, 1844) that "the accumulative vigour of all plants is exactly in proportion to the progressive agency of the causes to which they are first subjected." Many years' experience has convinced me that the larger the quantity of mould in pots, within reasonable limits, the more rapidly and safely are plants capable of acquiring vigour; other processes interfere more or less with their vital organs. To remove a plant from given conditions before it is capable of availing itself of such conditions, is opposed to reason and sound practice. In all cases of defective drainage in pots, it is found that the mechanical arrangement is unequal to the external pressure which acts upon the material.

When the principal buds are formed as young branches, they may be shifted from small, or large 60, to large 48 or 32 pots, according to their vigour, using two parts turfy friable loam, 2 of well-pulverised cowdung or leaf-mould, with upwards of one-sixth of sand. If the soils are such as to part readily by the hand, which, in a turfy state, is a certain test of its being well pulverised, sifting may be dispensed with; if otherwise, for the first shift, the soil may be passed as closely as possible through a sieve of 6-eighths or 1 inch in the wire; and in all cases when the several parts are sifted, the whole of the portions should be passed through together, and not separately—the latter method reduces the texture too much. Previous to shifting, the plants should be in a uniform state of moisture, or, otherwise, well watered when turned out of their pots, so that surface-watering may be dispensed with for one or two days after potting; during which period, the newly-applied soils being exposed to the influence of sun and air, become less retentive, and more fitted to receive repeated waterings.

In the process of potting, the bottom-drainage should (especially in the first operation) lie tolerably loose over the bottom cavity, the potsherds or other material lessening in size upwards. The sub-drainage of coarse flakes of partially-dried leaf-mould, or cowdung, or dry open turfy loam, should be pressed tolerably firm. Of the soil generally, the coarsest and most open portions should occupy the lower and middle positions in the pot, and the finer should be towards the top. As to pressing down soil in potting, that should be regulated in proportion to the vigour and size of the plants: being most considerable on the lower portions, and slightest towards the surface. The smaller the plant, in proportion to the quantity of soil in which it is placed, the more uniform and slight should be the pressure. The entire surface of the soil should slightly incline towards the edge of the pot; but this should not be managed by greater pressure round the edge; the soil should be originally arranged in that way.

After the first process of potting, the plants are to be placed upon inverted pots on the front platform of the forcing-house, to admit a better exposure to air and light, and for the first forty-eight hours they should be plentifully syringed; then, morning and evening, the front lights being closed for the time stated; and if sun-light becomes powerful, they should be shaded from 11 to 2, 3, or 4 o'clock, in proportion to its intensity, if in a west aspect; or earlier and later if facing the east.

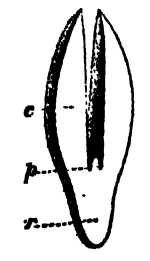
After the surface soil shows that it has been sufficiently exposed to the air, by beginning to require water, the plants may, in the first instance, receive enough to pass through the whole amount of soil. The second application should be applied with judgment, and, to avoid excess, may, in part, be supplied by a copious syringing. Such precautions may appear trivial and unnecessary, but a difficulty will be found in drawing a line between the application of water to recently heavy-shifted plants and others. Alternate syringings are more beneficial for a short period, in such cases, than repeated waterings, allowing for casual exceptions.—*William Wood, Pine-apple Place.*

ON THE CULTIVATION OF GRAPES IN POTS.

THE first impulse given to fruiting Vines in pots was by a paper in the "Horticultural Register for 1831," by Mr. G. Stafford, then gardener at Willersly Castle, in Derbyshire, and which at the time elicited much surprise. Through him I became practically acquainted with the system he followed; and since then having been more or less engaged annually in preparing and fruiting a considerable number of Vines in pots, I can safely bear witness to the successful results that will follow the practice detailed below.

After fixing on the kinds of Vines you intend growing, the first thing to be done is to procure eyes (or buds) of the required kinds, from some known good bearing Vines, taking care to have the wood perfectly hard and ripe, with the eyes prominent and round. If the Vines are intended to be fruited the next season, the eyes should be potted in 32-pots, placing them one inch below the surface, and using soil of a light turfy nature, or if stiff, adding a portion of half-decayed leaves; only one eye must be planted in each pot. This should be done early in February, and when finished the pots containing the eyes may be plunged in any pit or frame that may be at work, where a bottom-heat can be maintained of 90°, or thereabouts. They may remain there until growth has commenced, when sun-light being indispensable to the welfare of the young plants, they should be placed (if they were not previously) as near the glass as possible, sinking the pots as the plants reach the glass, but still keeping a steady bottom-heat, and supplying them with air every day if possible. It is supposed that the heat of the frame or pit varies from 80° to 90° in sunshine. When the pots are filled with roots, which will be some time in April, they may be transferred at once into their fruiting-pots, which should be 2s or 4s, according to the strength you wish your Vines to attain; bearing in mind that those in the smaller size will ripen their wood earlier, and consequently be available for forcing at an earlier period than the others. This operation will bring us to a consideration of the description of soil or compost most suitable for the Vine. When growing naturally out of doors the Vine will flourish in a variety of different soils and composts; but when its roots are confined in so small a space as a pot, we must place within the action of its roots that kind of soil from which it can most readily assimilate the elements which constitute its food. After trying nearly all the different composts recommended by the numerous authors on the Vine, I am convinced that the more simple the constituents of the soil are for it, or any other kind of pot-plant, the more successful will be the results. The compost I use is two-thirds turfy loam, from a down having a chalky bottom, and one-third decomposed night-soil. Should the loam be strong, I use the same proportion of half-rotten horse-droppings. The turves in the loam should only be half decayed, and it should be used as rough as possible.—*John Spencer, Gardens, Bowood.*

(To be continued.)



FAMILIAR BOTANY.

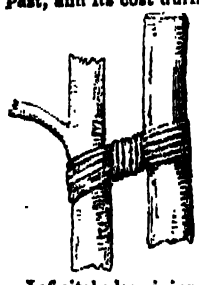
MORPHOLOGY, No. IX.

Lo! on each seed, within its slender rind,
Life's golden threads in endless circles wind;
Maze within maze the lucid webs are roll'd,
And, as they burst, the living flame unfold.
The pulpy Acorn, ere it swells, contains
The Oak's vast branches in its milky veins!
Each ravell'd bud, fine film, and fibre line,
Traced with nice pencil on the small design;
Grain within grain successive harvests dwell,
And boundless forests slumber in a shell.

THE manner in which the embryo plant of the Yew-tree is formed is essentially the same as that which is observed in all other flowering plants; and therefore, without confining our attention to the Yew, we may now proceed to consider in its general sense the value of the knowledge gained by an examination of the manner in which the embryo Yew goes through its various changes till it arrives at that first stage of perfection in which it may remain asleep, for ages perhaps, until the fitting circumstances awaken its germinating powers, and call it into a new and active life.

It is plain that the embryo of the Yew was at first a few microscopical bladders, arranged in a loose and apparently confused manner; that through various changes it arrived at another and much more perfect condition, in which the bladders are collected into a solid mass, having a definite form, with a pair of lobes at its free end. Let us now suppose that the annexed diagram represents some such embryo plant cut through lengthwise, and placed erect instead of being inverted, like that of the Yew. Three parts are then distinguishable, viz. *c c*, which are called cotyledons; *p*, a point between their bases, called the *plumule*, or in a general sense, the *growing point*; and *r*, a cone, extended downwards, and named the *radicle*. Here we have the whole preparation which Nature makes wherewith to fashion out a plant, with its leaves, stem, flowers, and fruit. In no seeds have we anything more—in some we have not so much. We have nothing whatever except a collection of little bladders, gathered together into a definite form, invariable in each species, and provided with the wonderful power of working out of such materials all that hereafter may be proper to its nature. The cotyledons are, in fact, the first leaves, sometimes having a peculiar shape, but often not distinguishable from those which succeed them. The plumule, or growing-point, is that which lengthens upwards, and changes into a stem clothed with leaves, flowers, and fruit. The radicle goes downward, and gives rise to the root. The embryo is, in fact, a young plant, whose bones, sinews, and breathing apparatus are not yet formed, but out of which they have to be developed: and it consists of a root and short stem, with one pair of leaves upon it; or, to use the language of morphologists, of an axis and its appendages. The axis gives birth to all the future ramifications above and below ground; the appendages are the rudiments of what, in one state, are called leaves, in another, flowers, in a third, fruit, as I shall next proceed to show.

When the poet exclaimed that "every heart contains proportions germ," he did not dream, perhaps, of the extent to which that beautiful truth may be applied. What crowds of proofs rush forth the instant that the veil of Nature is withdrawn but for a little space!—*R. E.*



REMOVAL OF TREES.

WOULD any of your correspondents oblige me with their opinion respecting the best time for cutting a trench round large trees to prepare their roots for future removal? Winter seems, according to my practice, to be preferable to spring, after the buds have begun to swell; and it is possible that autumn, or as soon as the leaves begin to fall, may prove a still better period for that operation, and that the descending sap would form the commencement of new roots, in lieu of wood on the stem, in readiness to shoot with vigour in the spring. This experiment was neglected last autumn, but it probably required a trial on an extended scale, in consequence of the variable growth of the roots of trees under apparently similar conditions. The question is asked, in the hope that it may meet the

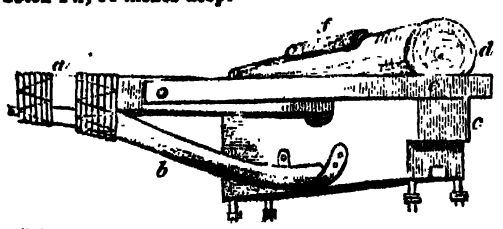
eye of parties willing to try comparative experiments in different soils and situations.

A rapid formation of roots has been remarked to have taken place in autumn in large shrubs (Laurels) which were taken up last September, and heeled close together with some loose earth thrown over their roots, for subsequent planting at leisure during winter. And a similar occurrence was observed some years ago in similar shrubs that were lifted, and replaced in their holes in August: their subsequent removal about November was remarkably successful. Loose earth seems more favourable for the formation of young roots than the tight packing of the balls, according to Sir Henry Stewart's method, adopted when more care and attention is paid to the removal of better plants; yet this last operation *is* essentially necessary, before the ground is dried up by summer heat. On the whole, the double removal seems to have been most successful. Doubtless good roots will be formed by early autumn cutting. The question may be asked:—"Will it be at the expense of the buds for the ensuing year?"

Having adopted some variations in the mode of taking up large trees from that recommended in the "Planters' Guide," which tend both to reduce its expense and risk of injury to the roots, I will venture to detail the method in which that operation has been conducted for some years past, and its cost during the present season.

As soon as the surface-roots have been cleared in the trench, the tree is firmly secured to a pole, of 22, instead of 15 feet in length, by three or four lashings formed of five or six rounds of 1-inch rope, frapped together. The carriage and tree are then hove down by a purchase applied to the top of the pole, consisting either of two single blocks, or a single and double block, and a 2½-inch rope (shroud laid).

Infinitely less injury seems done to the lower roots by tearing them up than would be occasioned by undercutting the ball, while the surface-roots entirely escape the handling and turning back that would otherwise be required to enable men to work below them.



The strain on the carriage and stem of the tree is, however, extremely severe; but the bark of Turkey Oaks of 8 inches in diameter is capable of lifting near 2 tons of earth without injury, in ground that is unfavourable for the formation of tap-roots, when properly secured, that is, wrapped up in pieces of old sacking. Only one soft-barked tree (a Lime) has been removed exceeding 8 inches diameter near to the roots; it bent under the weight, about 2 tons of earth, and, had the least slipping of the lashings occurred, it is obvious the bark must have been stripped off. The bark has been injured for a few square inches, where it bore on the straw matting. The plan is clearly not suited for such trees.

While some of the men are employed in tying up the branches, one of them shifts the upper block from the pole to the axletree; 5 or 6 fms., however, of rope, fixed to the axle, would be preferable, as the block could be hooked on at once; the carriage is then quietly drawn out of the hole by a horse, at just one-third of his speed. In many cases it is requisite to shift the purchase, so as to draw out the carriage with the roots forward. The work done in five days by four men was—an 8½-inch tree in diameter in the morning, and a 6-inch tree in the afternoon. A horse was brought by another man at half-past 10, and at half-past 3 o'clock, which are charged at half a day each.

A load of compost . . .	1 6
	10 6

To this must be added an hour's work for two more horses, if the tree is removed up-hill. The larger tree may be taken at 6*s.* 6*d.*, and the small one at 5*s.*; their average height was about 35 feet.

The carriage is roughly made; its cost was 2½ days' labour for a carpenter, and 2 days for a labourer to assist, and about 25 lbs. of iron-work to fix it on a pair of strong and broad cart-wheels, 6 inches wide, and 4½ feet high. The pole is a small-leaved Cornish Elm, exceeding 8 inches in diameter at bottom, and rather less than 6 at top. The bed was adzed out of a waste piece from the fork of a large Scotch Fir, 18 inches deep.

a. Pole of Elm, 22 ft. long, 8 in. diameter at bottom, and 5½ at top.
b. Ash stay, gammoned up to the pole with inch stuff.
c. Rough piece of Scotch Fir, adzed down.
d. Do., Scotch Fir. *e.* Side stays. *f.* Mat of straw.
The pole is placed high, to enable the lashings to be made more secure.

On calculating the solid contents of wood in the carriage in cubic inches, it amounts to about 11 solid feet, hence its weight is about 5 cwt.; and about 3½ tons would be the probable limit of the load for the axletree.

The wood in the previous carriage was crushed, in consequence of decay, and the axletree was bent by the strain in taking up a tree.

It is obvious that the success of these operations is entirely dependent on the lashing of the tree securely to the pole; it can be managed with the greatest ease, if a labourer can be found who has been a few months at sea, otherwise great attention must be paid to this point, and perhaps some failures from slipping will occur.—*E.*

Home Correspondence.

Whitney's Composition.—To the many notices of the successful application to the purposes of Horticulture of Mr. G. Whitney's (of Shrewsbury) Transparent Composition which have appeared in your columns, permit me to contribute the following, which I doubt not will be perused by your numerous subscribers and readers with similar gratification which resulted to myself from its examination. During the last few weeks Mr. Whitney has erected in his garden a house 28 feet long by 12 feet wide and 15 feet high, covered entirely with muslin prepared with his Transparent Composition. Internally the house is divided into a stove-pit, heated by a hot-water apparatus; and a greenhouse or conservatory. In the stove a Vine (Black Hamburgh) has been introduced (for experiment), which bids fair in a very few days to be clothed with healthy and luxuriant foliage. Cucumber plants inserted there are thriving well, and never flagged or drooped in the least on their removal, although not shaded. In the greenhouse compartment Pæonies, Fuchsias, and other plants, are healthily putting forth strong and vigorous shoots. Indeed, the whole promises speedily to be a scene of great beauty and luxuriant vegetation. Nor can it fail to be so, the light being so clear, abundant, and yet subdued, being very similar to that reflected from a white cloud, quite unaccompanied with any glare, and admirably and equally diffused throughout every portion of the house by the singularly radiant and repeated reflections from the white coverings, walls, and surfaces. The temperature in the stove, which is usually kept at 80°, is well and uniformly preserved, the air-tight nature of the whole apparatus not suffering it to fall more than a very few degrees even during the late cold and severe frosty nights, although very little fire has been kept up. In addition to all this, economy speaks loudly, the cost of the prepared muslin not having exceeded one-fifteenth that of glass for an erection of similar dimensions. I trust to hear that so successful an example has been followed throughout the kingdom, and that the time is near at hand when every one devoted to gardening in any department, however humble his means, will be found gratifying his taste in the possession of greenhouses, &c. similarly constructed, with this useful composition, for the ingenious invention of which the cordial thanks of high and low are abundantly due to Mr. Whitney.—*Botanophilos.*

Durability of Oak.—There can be no doubt that the supposed date, 1035, on the Oak-beam taken from a house near Oswestry, is not of the time assigned to it. One of the earliest authenticated instances of the use in Europe of Arabic numerals is the date 1375, written by Petrarch on a copy of St. Augustine's works. When the use of these numerals was first introduced into England is doubtful, but they were, at all events, not used in keeping the accounts of the English colleges till near about the beginning of the 16th century, and it is very unlikely that they came into vulgar use till long afterwards; they are of rare occurrence in writings of the first half of the 16th century. But is it certain that the figures 1035 were used for a date at all? May they not be the mark denoting the number of a lot of wood, or the private mark of a tradesman?

The Vine.—There is a very singular and perplexing statement by "R. P." at p. 166, respecting the fruitfulness and unfruitfulness of his Vines, that are subjected to the heat of a fruiting Pine-stove. The subject is worthy of the attention of practical men; it opens up a wide field for discussion. "R. P." prunes his Vines on the spur system, which is good; but why does not the shoot trained across the bottom of the light and up the adjoining rafter bear equally with the parent stem? First, is caution used to make the wood on both rafters break its buds at one time? Although the wood is ever so promising on the adjoining rafter, if the parent stem breaks its buds while the other is dormant, I have not the least doubt but that what would have been fruit on the adjoining rafter will be converted into tendrils; the organisable matter stored up previously, and while the Vine was at rest, should the parent stem take the lead in breaking its buds, will be drawn to the support of them, more especially as it has a clear upright course, not receiving a check in having to flow horizontally before it reaches an upright position, as in the other stem. There is still some mystery with regard to the Black Muscat (a Grape I am not acquainted with—perhaps a synonyme of the Muscadel or Morocco, neither of which is calculated for a fruiting Pine-stove, being late Grapes: should it approach its congener in size of bunch, berry, and flavour, it will be a desirable variety). There is no obvious reason for its sterility, unless, being a late Grape, it is impatient of heat at an early period, which experience teaches is one great reason of its being abortive. I should wish to be informed regarding "R. P.'s" system of summer-pruning, and whether he follows the system of disbudding, as mentioned in my treatise on the Vine, as on that, and attention to the roots, will, in a great measure, depend the fruitfulness of his Vines. The following case occurred here last season. I have three succession Pine-stoves, with upright glass in front, 2 feet 6 inches high; the rafters and back walls are covered with Vines, besides a late Vinery. In my earliest house of Grapes, which is one of the above Pine-stoves, I had, at the time of planting, in 1839, to one of the rafters planted a White Muscat, which proved wrong to its name, and turned out to be a Black Morocco (which is a valuable late Grape, and keeps equally well with West's St. Peter, but it is not suitable for an early house); last season I cut it away, intending to bring in a white Muscat in its place. On the adjoining rafter is a Hamburgh; after it had pushed shown fruit, and the shoots were stopped, a thought struck me of carrying out my method of disbudding still farther, and marking the result; accordingly, I selected the bud on the lowest spur below the angle of the rafter, near where the stem of the Vine entered through the sill in the wall, and conducted the young shoot as it progressed in growth across the bottom of the light and up the adjoining rafter, taking off all tendrils and laterals as they appeared, and disbudding the shoot, as I do in autumn, as it advanced in growth, or as soon as I could perceive that the buds were formed. This, by many, would have been thought a dangerous experiment, operating on the growing shoot. I then stopped it at 14 feet in length, including the portion across the bottom of the light and to the bottom of the parent stem, intending to prune it back to 12 eyes; I allowed three laterals to remain at the extremity of the shoot, to keep it in check, which I stopped with caution, and removed altogether in a few weeks afterwards. I left 12 eyes for spurs, 6 on each side, and not a single bud broke untimely under the experiment: using caution, the buds broke with the parent stem when I began to force; and the result is, that this season the 12 eyes have shown 31 bunches of Grapes. I forward you a specimen from a young cane of a Cannon Hall, carried up in a similar manner, that was not disbudded while it was growing, but operated upon (according to my usual practice) when it had attained its full growth; it has shown three and four bunches at one eye: the specimen sent is from an eye producing four. If "R. P." will observe the following three points, viz., timely stopping at summer pruning, in order to induce his Vines to make strong wood; disbudding as soon as they have made their summer growth, or, with caution, at the time they are making their growth, taking care that they break the whole of their buds regularly, under as low a temperature as is consistent with the welfare of his Vines; and paying attention to the root—I imagine he will find little cause for complaint.—*James Roberts, Ashton Hall.* [The specimen sent promised to be a very large bunch. It contained 2816 flowers!]

Old Wall Nails.—When a boy, many a long cold day I have sat in a cold shed on a stool, having a square piece of iron fixed in one end, similar to what a blacksmith makes use of in preparing horse-shoe nails, with a hammer, rap, tap, tapping, cleaning and preparing in readiness old wall nails for the men who were nailing and training the wall-trees. Many a tap it required to get one thousand cleaned for use, letting alone, if possible, any extra raps on the thumb or forefinger when the hands were cold. I then resolved, if ever I should myself get master of a place, and have old wall nails to clean, that I would adopt some more expeditious method. When attending Covent Garden Market, I observed that the fruiterers had a very clever and expeditious method of cleaning old Nuts and Walnuts of dust and mildew; putting a quantity into a sack or large bag, a person took hold of each end of the sack and worked it to and fro to each other, in the same manner that two stone-sawyers use a cross-cut saw; the friction soon cleaned and brightened both Nuts and Walnuts. By turning them into another sack, and dropping a very small portion of oil among them, and well working them in the same way, the Nuts would look as clean and bright as if they were quite new. Imagining that it would be a famous plan for cleaning old wall nails, I took the first opportunity of putting it into practice; it answered my expectations admirably: putting about five thousand into the sack at one time, along with two or three handfuls of coarse, sharp, river or sea sand, and working them as above recommended, in about twenty minutes or half an hour's friction they turned out as clean as new pins. By turning them into a suitable sieve or basket, the dust may readily be separated, and thus all the old nails of a large garden may be thoroughly cleaned in a few hours; if they are particularly wished to be kept free from rust afterwards, you have only to drop a small quantity of oil amongst them, and give them another good working in the sack.—*Observer J.*

Seed Steeping.—If I understand the theory of the steeping process, the body of the seed, i.e., the cotyledons or what answers to them, being of a lower order of organisation than the germ or actual seat of active vitality, is charged by art with a larger quantity of saline and other parts than what was originally furnished by nature; that the germ, on being awakened to growth, and finding an unusual supply of nourishment, vegetates with a proportionate vigour of growth. This I can understand, but that the process, upon the above principles, should so entirely influence the vegetation of a whole season, as possibly to render subsequent manuring unnecessary, is not so easily conceived. The effect of this earliest of all manuring so instant upon germination, and as it were so close to its work, appears to be to induce in the case of the cerealia a profuse tillering or production of fruitful shoots. Now, a plant, like an animal, is increased by the assimilation to itself—to use an old-fashioned term—of certain heterogeneous substances derived from without; in other words, by absorption by root and otherwise of various mineral and organic substances, and by its own peculiar system of combinations, converting them into its own substance. When, then, the young embryo has consumed the nourishment afforded by its placenta, and Mr. Bickes's sulphate of ammonia into the bargain, and is thrown upon a barren world to seek subsistence, how is it by its multiplication of parts more capable of production than before? and will it not feel want of food, with its superior number of mouths, equally with any unpickled companion? It would appear that a saving of seed may be effected, assuming that three seeds affording two stems each, are no better than one with three, the amount of

nourishment being the same. The opinion of Mr. Campbell, or any one conversant with the subject, would, I am sure, be as acceptable to many readers as to myself.—*Micklewell.*

Morphology.—If this doctrine is a fallacy, as some assert, why is it that the art of the cultivator can have any influence in bringing plants into a blooming state? How is it that we hear and read of certain modes of treatment causing plants "to grow to leaf, and not to blossom?" and others, again, by means of good management, even in artificial cultivation, made "to exceed the splendour of native specimens?" I imagine it may be referred to Morphology; for I conceive that it seeks to establish these most important truths, viz.,—firstly, that all vegetable bodies, varying as they do in their appearance, are but modifications of the same kind of matter, created by the same power, from the same source—nothing, and imbued with a mysterious property of extension and reproduction; and, secondly, that this matter is not, indeed, convertible from one organ to another, but capable of being developed either in one form or the other, as the circumstances to which it is exposed may have influence over that development. And, if this is Morphology, then every gardener daily demonstrates its truth; for why else does he prevent the blooming of annual plants when he wishes to preserve them beyond a single season, or, on the other hand, why does he adopt any particular course of treatment to induce a state of bloom in his plants? This refers to cultivated plants, and these being removed both from their natural situations and the natural circumstances of their growth, afford the strongest proof of the correctness of the science; for, why else could their removal from their natural circumstances influence the nature of their development at all? This by no means interferes with the order of Nature's laws; flowers are flowers still, and leaves are leaves, but what would be leaves, under certain conditions of growth, would be flowers if those conditions were changed soon enough, and the requisite conditions supplied. In all this there is no imputation of imperfection—no atheism—no infidelity.—*T. Moore.*

Cement.—I have used with unvaried success for joints to pipes and fittings for steam-engines of 14 and 16 horse power, a composition formed of iron-filings, muriate of ammonia or sal ammoniac (quantities indefinite, say four ounces to one pound of filings), and a small quantity of brimstone in powder, mixed together with water, so as to form a stiff paste, to be well rammed into the crevices and joints. Another is, ground white-lead, and a sufficient quantity of red-lead powder mixed, so as to make it of the consistence of stiff putty; this is spread on a flange of millboard on both sides, and placed between the pipes or joints.—*W. Rayner.*

Transmitting Cuttings to India.—All the cuttings that have been received at Calcutta by the Overland Mail, had been taken from the middle of last year's shoot, or nearly so. Such cuttings of plants that are difficult to propagate are never used in India, as they are considered useless. Our mode is this—1 or 2 joints or eyes of last year's wood are cut off along with the whole of this year's wood. If the shoot is not too long for a large hand or bell-glass, it is not topped; but if it is, we cut it to a reasonable length, say six or seven inches. The cutting, when made, is somewhat in this form ⊥. Before sending them from England (if the shoot is too long), as much of the top as is necessary may be cut off, provided five or six eyes or joints are left. I beg to mention that I only refer to plants that are difficult to multiply from cuttings in any climate. Some time ago Mr. Beaton says, "August is the best time for taking the first steps for preparing cuttings of fruit-trees, &c., destined to go by the Overland Mail next November to India or China. With regard to Hindostan, from experience I can say that August or November are not suitable months to send cuttings here; for the following reasons—the rains set in in June, and cease in October; the rainy season is best for raising plants of any kind, whether hard or soft-wooded, from cuttings; and if they are sent here by the November Overland Mail, the time mentioned by Mr. Beaton, they arrive here during the dry season, and only a few weeks before the commencement of what we call our hot season. We are glad if we can only keep life in our plants during the hot months. The time that cuttings should be sent to India is at the commencement of the rains, about the 20th of June; although they are a fortnight later it is of little consequence, but they should not, on any account, be sooner, as they will not succeed. Cuttings taken off in the winter or spring pruning, and 'heeled' in the ground until the grafting season, are the sorts that are likely to succeed, provided they are taken off with a little of the old wood attached, as already mentioned. We never put in cuttings of hard-wooded plants in the dry or hot months, as they root so readily under glass during the rainy season, being simply shaded from the hot sun with mats.—*R. Ross, H. C., Botanic Garden, Calcutta, Nov.* 3. [Sending cuttings to India in April and May, exposes them to travel in the driest and hottest time of the year. To put cuttings of European trees into the ground in the tropical climate of June, although best suited to the plants of such latitudes, is of doubtful expediency. The true course appears to be that adopted at the India House, by Dr. Royle, of sending all European plants, in the first instance, to Saharunpoor, in the quasi-European climate of the hills, where they can be easily established and prepared for subsequent transmission experimentally to Calcutta. Many of our European plants thus sent, are now flourishing at Saharunpoor, under the care of Dr. Jamieson.]

Bees.—A "Lover of Bees" may rest assured that there is no probability of the Bees seen hovering about the place where their hive had been taken from, joining with those in the other hive; they would soon find the way to their own. Why the hive was tenantless in spring, whilst it contained "about a stone of honey," is probably, owing to there not being a sufficient number of Bees reared in autumn to supply the places of those that die off. If the second swarm had not left the stock, the case might have been otherwise; for most of the Bees in it were young ones, and would have been the principal stay to the hive during winter and spring. In all cases that have come under my notice of Bees dying whilst they had plenty of honey, there was always a sad falling off in their numbers in autumn. A few days ago, I found in one of my boxes a handful of dead Bees at the top between two of the combs, where there was little or no honey, but there was plenty in the others, and it is easily got at through the thoroughfares or holes in the combs. This contradicts the statement, that "except hives are sticked there will be no passages through the combs."—*J. Wighton.*

Bees.—The season has commenced for examining stocks which have survived the winter; they should now be gently lifted up from their stands, and have the floors thoroughly cleaned, removing all dead Bees, particles of broken combs, or any filth that may have accumulated during winter. It is sometimes necessary to scrape the floors, using for the purpose a strong carving-knife, or sharp garden-trowel, in the first instance; and then finishing them with a stiff hair-brush. It is advisable to place the hive upon a broad board, or stand, during the short time required for cleaning. When the floor is finished, carefully place the hive exactly upon the spot from which it was removed, and endeavour to do so without injuring a single Bee, as they are all required at this season. The entrance, or door-way, should next be carefully attended to; it may be enlarged or contracted as the number of Bees require it, but never allow the opening to be more than three-eighths of an inch high, and six inches long; this size is required previous to and at the time of swarming. This is a matter of more importance than many Bee-keepers are aware of, as it prevents robbers from entering, either in spring or autumn, and allows the Bees an easier passage in and out during summer. These things being attended to, next endeavour to ascertain what honey is in the hive for the support of the Bees during the next two months; if it is scarce, do not neglect to feed them abundantly. Several articles on feeding were given in the *Chronicle* in the early part of last spring; which, if attended to, will save many poor stocks from starvation, and ultimately render them more productive than might have been expected.—*W. Savage, Swaffham, Norfolk.*

The Balsam.—Having some three-year-old seed, sowed it last year in the first week of April, in 24-sized wide-mouthed pots, and placed them in a Cucumber-frame. When they were up, and had fully expanded their seed-leaves, I removed them to a warm part of the greenhouse, taking care to keep them free from damp. As soon as they had attained sufficient strength, I potted them off singly into 48-pots, inserting them in the soil up to their seed-leaves, and plunged the pots into a tan-bed, where they had a bottom-heat of from 50° to 55°. The plants were kept as close to the glass as possible, and they had plenty of air given them in fine weather. I supplied them plentifully with water, and syringed them over-head when the house was shut up in the evening, as they are fond of a damp atmosphere. By this treatment the plants soon became strong and bushy. All flower-buds were removed as they appeared, until the plants were finally potted into 24, 16, or larger-sized pots, according to the growth I wished them to attain. The compost consisted of one-half strong loam, well mixed with rotten dung and old brick rubbish; it was prepared three weeks previously, and placed under cover until it was required. Before plunging the plants the last time, the heat in the bed was renewed, by forking the tan over, taking care to maintain the heat the same during their growth. The plants are occasionally turned, in order to keep them straight. As they came into flower, they were removed to the greenhouse. While in bloom, I supplied them plentifully with water, which they require then as well as throughout the various stages of their growth. The greenhouse was well-aired, in order to preserve them longer in bloom.—*J. F. M'Elroy, Clapham-common.*

Grafting the Luculia.—I have been more than once reminded that I ought to fulfil the promise I often made last year with regard to grafting this plant, which is difficult to increase by cuttings. The truth is, after I mentioned the subject, I felt a diffidence in recommending one stock more than another, for the purpose—as in such a very large order as the Rubaceæ, to which the Luculia belongs, there must be many plants on which it might be easily grafted. During this spring I found a much better stock for it than the one I used last autumn, and perhaps one that will answer better; experience alone, however, must prove this. Of late years most gardeners have studied the affinities of plants more or less, and with such men it is not a question whether this or that plant can be grafted on others of the same nature, but which of them is best suited for the purposes of cultivation. The way to determine the choice of a stock in a case of this nature is easy enough, if you graft evergreens on evergreens only, and deciduous things on deciduous; but this rule is violated every year: then the periods at which the two plants naturally begin to grow and go to rest, should correspond as near as possible; and lastly, they should correspond in the size they attain under cultivation; besides, the stock in all cases ought to be more hardy in its constitution. If the plants thus agree, and yet are known to differ in respect to the soil in which they grow best, we are satisfied in practice to use that soil which is best for the stock; but this is a point in gardening still open for experiments; however, when the Rhododendron flourishes in clay and strong loams, so different from its natural soil, we may rest satisfied in preparing that soil which we know to suit our stock, although the plant from which the graft is taken might refuse to grow in it. Nauclea Cadamba is the stock I used for the Luculia last year; it is well suited for it in all respects, except that it is a stove plant, and for this reason I object to it, and to many others equally suitable among Gardenias, Hymenodictyons, Exostemmas, &c. The plant I now use, and which I think is the best in every respect, is Burchellia capensis; and I do not know of any other plant in this large order which is more likely to make a permanent stock for the Luculia; and, no doubt, plants of it worked on this stock will be found easier to manage by those who find any difficulty in growing this, the most lovely of all our late flowering plants, when well managed.—*D. Beaton.*

Miscellaneous.—*Petts* states that a packthread-string, about 6 inches from the ground, round a bed of Cabbages, is a sure protection from rabbits.——*A. R. C.* begs to suggest to all Bee-keepers the advantage of sowing at this season a small patch of Bokhara Clover. It flowers late, continues long in bloom, the Bees are particularly fond of it, and it gives a very high flavour to the honey.——*Mr. C. H. Smith*, of 41, Queen-street, Edinburgh, sent a cut specimen of Camellia sasanqua that had been raised and flowered in a Ward's case. The flower was of the usual size, well-coloured, and perfect in every respect; the foliage was of a healthy deep green. Mr. Smith states that it was planted in May, 1842, and has flowered this spring. He informs us that, in the same case, plants of Epiphyllum truncatum, and speciosum, flowered beautifully through the winter, as did also the Cape Jasmine last summer; one of the flowers of which measured three inches in diameter. The case is about 42 inches long, 18 wide, and 4 ft. high; all were planted about the same time.——*William Bishop*, who says that he has had considerable experience in Pine-growing, informs us that he resided for three years near Thornfield, and that during that time he tasted several of the large Pines that were grown there by Mr. Hamilton. He mentions that one of those he tasted was a large Enville, the flavour of which, he says, was excellent; but still inferior to that of two large Montserrats, which he also tasted there. He states that the usual weight of Montserrats grown round Liverpool and Manchester, is from 2 to 4 lbs.; but that few reach the latter weight. Mr. Bishop writes that he has visited many Exhibitions in Lancashire and Cheshire; but that he never saw the Montserrat weigh above 4 lbs. He adds that Mr. Hamilton's Pines and Cucumbers are much superior to what is generally to be met with in that neighbourhood.

Societies.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

May 7.—This was the spring meeting; it was held in the hall at the Experimental Garden, Inverleith, Sir G. S. Mackenzie, Bart., V.P., in the chair. The hall presented a beautiful scene, each end being adorned with choice exotic shrubs, and the long table in the centre displaying in rich profusion collections of Camellias, Epacrises, Cape Heaths, and Hyacinths. The following prizes were awarded:—For the six finest and newest varieties of Camellia Japonica in flower, the Silver Medal was voted to Mr. J. Young, gr. to T. Oliver, Esq., Newington Lodge, the kinds being C. tricolor, Hendersonii, imbricata, rosea, carnea, and Vandesii; 2, Mr. J. Macnaughton, gr. to J. Wauchope, Esq., of Edmonstone, for Lady Hume's blush, double white, imbricata, fimbriated white, waratah, and double blush. For the two finest specimens of spring-flowering Cape Heaths, the Silver Medal was awarded to Mr. G. Stirling, gr. Melville Castle, for Erica hyemalis, and E. ariatata; 2, Mr. Young, for E. gracilis autumnalis, and E. Linnæoides. For five distinct varieties of double Primroses in flower, the Bronze Medal was voted to Mr. J. Thomson, gr. to W. Keith, Esq.; the kinds were white, yellow, crimson, Irish purple, and pale purple. For a beautiful seedling Epacris, the Silver Medal was voted to the raiser, Mr. J. Reid, gr. to Profes. Syme. It was a hybrid between E. impressa and nivalis, with elegantly-disposed foliage, and blossoms of a uniform hue, intermediate between the colours of the parent flowers. For the six finest Hyacinths, in pots, the Silver Medal was assigned to Mr. Thomson, for Ne plus ultra, Triomphe Blandina, Lawrens Koster, La Grande Vidette, Blocksberg, and Monsieur de Fesch; and a second prize to Mr. Young, Newington Lodge, for Grande Vidette blue, Grande Vidette white, Lord Gray, Lord Wellington, Grand Vainqueur, and Voltaire. For three collections of Flowers, two consisting of fine Hyacinths, and the other of beautiful seedling Epacrises, an extra premium was voted to Messrs. Dickson and Co. And another extra premium was assigned to Messrs. J. Dickson and Son, for a collection of rare Plants, in flower, including Centradenia rosea (a small Mexican shrub, densely clothed with blossoms,) Begonia coccinea, a seedling Gesnera fascialis, and Maxillaria Harrisonæ. A seedling purple Cytisus, raised at Biel, from seeds taken from a purple flowering branch which spontaneously appeared on a yellow Laburnum, was regarded as curious; and for this production an extra premium was awarded to Mr. J. Street, gr. at Biel. A hybrid Rhododendron, in flower, being a cross between R. arboreum album and R. Caucasicum, was exhibited from Dysart House garden; an extra premium was also voted for it. From the Nurseries of Messrs. Eagle and Henderson was a specimen, grown in a pot, of a shrub or tree raised from seeds received from New

Zealand, having the habit of a Pittosporum, but probably quite new. From the garden of Prof. Dunbar, were exhibited two Camellias in flower, one a seedling raised at Rose Park, the other C. Colvillii, with a fine specimen of Erica hyemalis; from Trinity Cottage-garden, a tall and well-furnished plant of Epacris impressa, in full bloom; from the garden at Biel, a most beautiful flowering branch of Acacia affinis, and a specimen of Calla Æthiopica in flower, raised from seeds ripened at Biel, where Mr. Street considers the Calla as completely acclimatised; and from a Ward-case, kept in the drawing-room of Mr. Smith, landscape gardener, Queen-street, flowering sprigs of Camellia Sasanqua, and Daphne odora. There were placed on the table packets of seeds of Bokhara Clover, presented to the Society by the Earl of Wemyss, and of Himalayan Coniferæ, presented by the Highland and Agricultural Society; and also various materials for making steeps for seeds, recommended by Prof. Johnston, presented by Lord Murray. At this meeting various communications were read. The first was an account by Mr. R. Foulis, Fordel, of the mode of dressing for table the tubers of Oxalis Deppei. The tubers are peeled, and the hollow centre cleaned out; they are then well boiled in rich stock, the fat being skimmed off. The tubers are served up hot, with a sauce prepared by heating a piece of butter and a spoonful of flour in a saucepan till browned, and adding a little stock. The next was a notice regarding the successful raising of various Himalayan Coniferæ, especially Deodars, at Elchies, on the Spey, in Morayshire. The seeds, which came by the overland mail, were sown on an open south border in spring 1842, and they all germinated freely. During winter a glazed frame was placed over a portion of the seedlings, but the rest were left wholly exposed, and were repeatedly buried in snow. In spring 1843 the plants left unprotected were as healthy and vigorous as those which had been under glass.—Then followed remarks by Mr. James Macnab on plants grown in water charged with various salts and manures, the specimens being exhibited in glass jars. One general remark was, that when only a small portion of liquid was placed in the vessel containing the plant, and the mass of roots was suspended above the liquid, the plant grew much better than when the roots were wholly immersed.—The next was a communication from Mr. Moffatt, Edengrove, recommending a four-pronged spade, a model specimen being exhibited. This spade he finds more useful than the common spade, when the soil is bound in frosty weather, or when it is very wet in rainy weather, and particularly safe in stirring the soil in shrubberies or in flower-borders.—The last was an interesting and lively account of the progress of Horticulture in Scotland during the last fifteen years, drawn up by the Curator of the garden.

GHENT ROYAL SOCIETY OF AGRICULTURE AND BOTANY.

The wealth, enthusiasm, and science, entering into the several parts, and forming the combined operations of this Society, taken as a whole, is certainly not surpassed at the present time, by any similar institution in Europe. It has existed since October 28, 1808, and conducted its operations with energy and prudence, as is abundantly proved by the fact, that the present is the 76th Exhibition of the Society; nor is its success less evident, when the improved state of botanical skill, displayed in all their gardening operations, is taken into consideration, especially with respect to whatever relates to propagation. The present Exhibition is the second forming a series of Shows of great magnificence, which are held every fifth year; other Shows are held by the Society (I believe four annually); but the one in question, which is termed "Festival Quinquennal de Flore," is, in all respects, a very great display, both of industry and science. The saloon in which these Exhibitions are held, has been built expressly for the use of the Society, and with especial reference to the Exhibitions; it is 300 feet in length. The centre is a lofty dome, 50 feet wide, supported by two wings, each 40 feet wide. The light is admitted at the roof, and in some cases at the sides; and the plants are arranged along each side, leaving abundance of room for the visitors to promenade without interruption along the centre, throughout the whole length of the building. Under the plant-saloon are offices for business; a small library, and other apartments occupied with specimens of Horticultural and Agricultural implements. There is also a refreshment-room capable of dining 200 persons. The general appearance of the plants, and the aspect of the whole arrangements, were in many respects different to the great metropolitan Shows in England. There were at least three times the number of plants exhibited, that are usually seen at the largest English Shows; but three-fourths of these would not have been considered admissible here, in point of culture, and very few of the plants were above mediocrity in this respect. Such is the zeal and desire for novelty, that both amateurs and nurserymen seem to lose sight of everything else; and such also is their skill and success in propagation, that with them the temptation is quite irresistible to cut up every leaf and bud of a new plant for the purpose of increase, and hence the general absence of well-grown and handsome plants of whatever is new. There is, nevertheless, much to admire and learn from their ingenious and scientific methods of budding and grafting. It is no disparagement to our Belgian neighbours to say that they do not excel in everything; in their knowledge and display of culture they are immeasurably behind the gardeners of this country. The leading features of this great Exhibition consisted of Camellias, Rhododendrons, and Azaleas; besides these, there was a great many collections of miscellaneous plants, both stove and greenhouse; and also hardy plants forced into bloom. The Camellia was, however, the great object of attraction, and is above all others the popular plant in Ghent; every amateur who can afford a greenhouse, however small, esteems it his highest honour, as it is by far his greatest ambition, to be possessed of a few of the newest varieties of the Camellia. In the mode of conducting the Exhibition, and more especially with respect to the manner of judging the plants, there was something of novelty, as compared with the method adopted in this country. Previously to the opening of the Exhibition, one or two days were occupied in collecting and arranging the plants; then one clear day was allowed for the proceedings of the judges; the next day, till 2 o'clock, was occupied in re-arranging the plants after they had been examined by the grand jury, and the prizes had been awarded; and the members, the grand jury (judges), and foreigners were admitted at 2 o'clock on the same day; the following day (Monday) was reserved for the grand jury, and the royal family and suite; then the three following days, the public were admitted without charge. The mode of judging the plants was conducted in the following manner:—The judges, or grand jury, were divided into two sections—the first consisted of 41 persons, and the second of 46; 15 of these were from Paris, 3 from London, 3 from Geneva, some from Germany, and others from Prussia, Holland, &c. &c. The operations, then, of this great combination of wisdom and science, were thus proceeded with:—Each judge was required to examine separately each collection or single specimen, as the case might be, without reference to any consideration or any agreement whatever with any other judge; his decision was written on a card, and thrown into a box or basket, and when each member of the same section had performed the same duty, the ballot or cards were examined, and whichever member had the highest amount of votes, was declared the winner. As the awards were thus determined, they were also announced by the firing of cannon planted in the adjacent grounds. It may be worthy of remark, that certain members and patrons of the Society forwarded for decoration various large plants, which were classed according to some arrangement, and dedicated to the honour of the Society; others to the King, as Chamærops excelsa, and Latania borbonica; others were dedicated to the Queen, as Chamærops Birro, and Phœnix farinifera; and so on, with several other classes of plants presented in homage of worthy objects. The following will convey some idea of the number and quality of the plants exhibited:—

Competition between Gardeners and Amateurs in the neighbourhood of Ghent.

Collections of 40 *to* 60 *Plants, in Bloom* (distinguished for their culture and variety).—1st prize to Mr. E. Rosseels, of Louvain, for Pimelia ligustrina, Bignonia cherere, Enkianthus quinqueflorus, Cratægus indica, Pultenæa daphnoides, Tropæolum pentaphyllum, Indigofera rosea, Chorozema varium, Billbergia amœna, Epacris grandiflora, and 19 other miscellaneous plants; Rhododendron arboreum alta-clerense, R. incarnatum, R. Nobleanum, R. triumphans gandavense, R. ponticum, Camellia jap. Cliviana, Colvillii, Donkelaerii, Press' Eclipse, punctata, imbricata, and 6 other varieties; Rosa, 6 varieties; Azalea ind. Smithii, amabilis, elata rubra, phœnicea, and 4 other varieties. *Collections of* 50 *Camellias, in bloom.*—1st prize to Mr. Glym, of Utrecht, for Camellia japonica punctata, King's, elegans Chandlerii, Sacoya nova, Daelenii, splendens, Stephanie, fimbriata, Ferdinandii, Susanna, Traversii, nobilissima, Lefevreana, imbricata, do. alba, alba Loudoniensis, Fraseri, resplendens, Cavendishii, Roi des Pays-bas, maculata, Colvillii spectabilis, maculata, Vandesii, Reevesii, Derbiana, Chandlerii, candidissima, Vandesii vera, Loudoniensis magnif, electa, striata, minuta, punctata major, electa (Casier), Queen Victoria, Gilliesii, Fordii, speciosa, futteng, formosa, Ferleyana, Campbellii, splendens, Thomsoniana, Stephanie, Vandesii superba, delicatissima. *Collections of* 15 *Rhododendron arboreum* (*hybrids*).—1st prize to Mr. Maurice Otin, of Etienne, for Rhod. arb. altaclerense, Russellianum sup., tigrinum, fulgens, superbissimum, delectum, Drummondii (sp. n.), amabile, formosum, sericeum, excelsum, hybridum nov., atrorubens, Smithii, and Knightii.

Competition between Gardeners and Amateurs throughout Flanders.

Collections of 25 *Forced Plants, in bloom.*—1st prize to Mr. A. Van de Woestyne-D'Hane, of Ghent, for Magnolia striata, Glycine sinensis, Kalmia latifolia, K. glauca, Ledum palustre, Pæonia arborea, Lilium Broussartii, and others. *Collections of* 50 *to* 150 *Plants, in bloom.*—1st prize to M. le Cher Heynderyex, of Ghent, Vice-President of the Society, for Dendrobium nobile, Lælia anceps, Maxillaria aromatica, Oncidium Baueri, Trichopilia tortilis, 14 varieties of Rhododendron arboreum, 9 varieties of Acacia, Banksia integrifolia, B. prostrata, B. intermedia, 9 varieties of Azalea indica, 5 varieties of Pæonia arborea, 19 varieties of Camellia, 7 species of Epacris, 20 species and varieties of Amaryllis, Crinum amabile, Clivia nobilis, Begonia coccinea, Ixora Bandhuca, and others, making a collection of upwards of 150 plants. *Collections of* 50 *to* 100 *Camellias, in bloom.*—1st prize to M. Alex. Verschaffelt, of Ghent, for a collection of 50 plants, including the following varieties, which were not included in M. Glym's collection, noticed above:—C. delicatissima, Kew blush, Colvillii, tricolor, rubra aurantia, Grunellii, Woodsii, do. alba, cœlestina, Pressii, alba plena, rubricaulis, Haylockii, Parkerii vera, Philadelphica nova, rosa chinensis, Sweetii, Lechmannii, ochroleuca, Youngii, reticulata, rubra plena, florida, gloriosa, picturata, coronata vera, Rollinii, Hendersonii. *Collection of* 12 *new Camellias, in bloom*, (exhibited in honour of his Majesty the King of the Belgians.)—1st prize to M. Alex. Verschaffelt, of Ghent, for C. Queen Victoria, Prince Albert, Fentonia, Marchioness of Exeter, fasciculata nova, Mathilde, imbricata rosea, alba mutabilis, picta nova, amabilis triumphans, alba plena nova, composita. *Collection of* 30 *Coniferous Plants.*—1st prize to M. Alex. Verschaffelt, of Ghent, for Araucaria imbricata, A. Cunninghamii, A. do. glauca, A. excelsa, A. Brasiliensis, Pinus tenuifolia, excelsa, Gerardi, religiosa, macrocarpa, (abies) Douglasii, Lamberti, Menziesii var. (abies), Fraseri, cephalonica (abies), Pinsapo, longifolia glauca, Phyllocladus trichomanoides, Dammara australis, D. orientalis, Dacrydium cupressinum, D. taxifolium, Juniperus pendula, Thuja pendula vera, Cupressus pendula, C. sp. New Zealand, C. australis, Podocarpus Totara, Cedrus Deodara. *Collections of* Rhododendrons, Azaleas, Pæonias, Roses, Amaryllis, Dutch bulbous plants, Orchideæ, Cacti, Ericas and Ferns, with various specimen plants, and minor collections, were exhibited. Among the collections of new plants, which were very extensive, was a most interesting one from Dr. Von Siebold, consisting of plants from Japan and Java.

Reviews.

Theory and Practice applied to the Cultivation of the Cucumber in the Winter Season, &c. By Thomas Moore. 12mo. Groombridge.

This little tract, like Roberts' excellent treatise on the Vine, is what it should be,—not only an explanation of the mode of managing the Cucumber in the winter, but also of the reasons for its management. We welcome its Author as another recruit in the good work of regenerating Horticulture, and of substituting for receipts, which are only to be compared to those in our grandmothers' kitchen-book, something like rational language, fit for the consideration of rational beings. If we could see Mr. Moore's example universally followed by competent persons, Horticulture would quickly receive an impetus which nothing could resist. The plan of a Cucumber-pit, which the Author proposes, although perhaps inferior to the Worsley pit (figured at p. 180), is one which will be found to suit some places better, and is, like it, a wonderful improvement upon the barbarous old contrivances for obtaining heat by fermenting stable-litter.

Dried Specimens of the Agricultural Grasses of Ireland forms a small thin folio volume, which Mr. D. Moore, the Curator of the Royal Dublin Society's Garden, has prepared for the use of farmers. It is not too much to say of this work, that it is one of the most useful things that can be put into the hands of a person interested in rural affairs, and unacquainted with Botany. Its very small price (6*s.*) places it within the reach of everybody. Young Gardeners, too, who are expected to know the common Grasses when they see them, will find it an excellent companion.

GARDEN MEMORANDA.

Lord Wicklow's Seat, Shelton Abbey, in the Vale of Avoca.—At this place is a tree of the Olea paniculata, nearly 40 feet high, a wonder to all the gardeners in the neighbourhood, and probably the only specimen in Great Britain, in the open air.

Sheffield Botanical Gardens.—A large house at this place is appropriated to the cultivation of Ferns, and is one of the most unique structures of the kind in this country. There is a walk near the front, and a flight of steps at each end leading to a gallery. Next the back wall is a platform, on which is placed in pots a collection of Orchidaceæ. The space between the front walk and the gallery is where the Ferns are grown. They grow on a rustic kind of rockwork formed with chumps of wood, rough roots of trees, and large pieces of petrifaction from the Derbyshire hills. The outline of the rockwork is broken into knolls, promontories, and bays in miniature, with pools of water seen in some places through rustic arches covered with those interesting plants. The interstices of the rockwork are filled with a compost of chopped sphagnum, heath-mould, and loam, in which the Ferns appear to delight, as the following dimensions of some of the principal ones will show—

	long	wide
Pteris longifolia, fronds	3½ ft.	1½ ft.
,, specimens from New Zealand	4½	3
,, Plumieri	4	3
,, arguta	4½	3
,, specimen from New Zealand, a most splendid plant, the entire plant being 6 ft. diameter, 4½ ft. high, with a circular rhizoma; the stems of each frond average 2 ft., and then divide into a quadripinnate frond, 20 fronds forming the entire plant.		
,, nemoralis, 4 ft. diameter	high	wide.
Cheilanthes repens, many fine fronds; one measures	9ft.	7ft.
Nephrolepis exaltata	5½	
,, tuberosa	3	
Allantodia coreovadensis	5½	
,, nemorosa	4½	2½
Antiogonium Seramporense	5	3
Aspidium coriaceum	3½	2½
Blechnum Brasiliense	3	3
,, occidentale	2	4 in.
Doodia, species, New Zealand, fine	2 diam.	

Lomaria Patterson, fronds 1 ft. 4 in. long, both barren and fertile fronds ramifying, a circumstance rarely seen.

Gymnogramma, new species, something like dealbata, a most extraordinary plant, diameter of the entire plant, 2 ft.; fronds, 3½ feet high by 1 ft. 4 in. wide.

Gymnogramma ochracea, 4½ ft. diameter, with hundreds of fronds, 2 to 3 ft. high.

Dicksonia antarctica, 3 years' old, fronds 3 ft. high.

Adiantum formosum, 3½ feet high, and many others equally fine.

One part of the collection is very fine. The lofty Cheilanthes in the back ground, Polypodium aureum, with its graceful fronds, overhanging a lofty promontory, on a lower portion of which stands a noble plant of Acrostichum alcicorne, 4½ feet in diameter,

and 3 feet high; whilst the pretty dwarf Niphobolus chinensis creeps round the base, and is in, what is rarely seen, full fructification. The hollows or bays of the rocks are filled with the dwarf species of Adiantum, Aspidium, &c. Altogether, it forms to the lover of those beautiful plants an interesting scene, and is well worthy of a visit to those who delight to study the beauties of the vegetable kingdom.—*T. Appleby.*

Northwood Park, Cowes.—We understand that 8 or 10 Eucalypti trees that were planted in the open air some time ago at Northwood Park, have hitherto passed through the winter very well, and that this season they have done better than usual. We learn that, although they are not more than four years old, from seed, they measure fully 20 feet high.

Miscellaneous.

The Mustard Tree of Scripture.—At a late meeting of the Royal Asiatic Society (the Earl of Auckland in the chair), an interesting paper on this subject was read by Professor Royle. He stated that he had been induced to bring the subject before the Society in consequence of having traced an Indian tree, chiefly by its Asiatic synonyme to be the Mustard-tree of Scripture. Having referred to the passages of the New Testament, Matt. xiii. 31, Mark iv. 32, Luke xiii. 19, &c., where the Mustard-tree and seed are mentioned, he next showed how unsatisfactory were the ordinary explanations respecting the common Mustard plant, and the total want of proof respecting the Phytolacca dodecandra, adduced by Mr. Frost. He then mentioned how his own attention was turned to this subject. Dr. Royle stated that having been asked by the then Principal of King's College, now the Bishop of Lichfield, whether he knew the Mustard-tree of Scripture, and having replied in the negative, he was informed that Mr. Ameuny, a native of Syria, and a student of the College, said he was well acquainted with the tree. Mr. Ameuny confirmed this statement to Dr. R., and added that he had often sat on horseback under the tree, which was, in Syria, considered to be the Mustard-tree of Scripture, and where it was commonly called Khardal. On this Dr. R. observed, "That is the Arabic name for Mustard." Mr. A. replied, "It is so, and in Syria the seeds are employed for the same purposes as Mustard is in Europe." Dr. Royle referred to a variety of sources to obtain some explanation of Khardal as applicable to a tree of Palestine, but was unable to proceed beyond the Asiatic names of three kinds, enumerated in his manuscript Materia Medica of the East. 1, *Khardal*, or common Mustard; 2, *Khardal barree*, or wild Mustard; 3, *Khardal Roomee*, or Turkish Mustard. The last would appear to be the tree, though there was no way of finding what tree is intended by these names in the Arabic works on Materia Medica. On referring to the Index of his "Illustrations of Himalayan Botany," he found the word *Kharjal*, which he was himself surprised to find one of the names of a tree in N. West India, apparently well suited to be the Mustard-tree of Scripture, though he had no proof that it extended into Palestine. This is the Salvadora Persica, first obtained from the Persian Gulf, which is there a tree of moderate size, with drooping branches, and leaves something resembling those of the Olive, with acrid bark, and edible berries. Dr. Roxburgh describes the same tree as common in the Peninsula of India, growing well in every soil, producing flowers and ripe fruit all the year round, with the inflorescence in panicles; the berries red and juicy, much smaller than a grain of black pepper, having a strong aromatic smell, and taste much like garden cresses. Retz had previously obtained the same plant from Tranquebar, and had called it Embelia grossularia. Forskal found it in Arabia, and called it Cissus arborea, stating that it was much esteemed by the Arabs, and even celebrated by their poets. Having traced this tree from India up the Persian and Arabian Gulfs, the author was still unable to find any authority for its being found in Palestine. On inquiry he was informed by Dr. Lindley, that he had seen specimens of the plant collected by Bové, near Mount Sinai. Captains Irby and Mangles, however, in their travels, mention a tree which they suppose to be the Mustard-tree of Scripture, and which Dr. R., even from the few characters given, has no doubt is the same tree, which he had traced from India, up the Persian and Arabian Gulfs, and from thence to Mount Sinai. These travellers mention, that advancing towards Kerak, from the southern extremity of the Dead Sea, they met with a number of curious plants, and among them, one which they observed in great plenty, and which bore a fruit in bunches, resembling in appearance the Currant, with the colour of the Plum. It has a pleasant although strongly aromatic taste, exactly resembling Mustard. We think it probable that this is the tree our Saviour alluded to in the parable of the Mustard-seed, and not the Mustard-plant, which we have in the north, and which, even when growing large, can never be called a tree; "whereas the other is really such, and birds might easily, and actually do, take shelter under its shadow." On further inquiry of Mr. Ameuny, Dr. R. was informed, that the tree called Khardal is found in the neighbourhood of Jerusalem, but most abundantly on the banks of the Jordan, and round the Sea of Tiberias: that is in the very locality where our Saviour appears to have spoken the parable of the Mustard-tree. There can be little doubt but that this is the same tree seen a little further south by Captains Irby and Mangles, and that it is to it that writers in the Talmud refer, under the name of Chardal—one describing a tree of which the wood was sufficient to cover a potter's shed, and another that he was wont to climb into a Chardal-tree in his field, as men climb into a Fig-tree. These statements have been sneered at by Rosenmüller and other Biblical writers. Dr. Royle concluded by stating, that though he thought that Captains Irby and Mangles had been the first to indicate this tree, though without any name, as the Mustard-tree of Scripture, yet he thought that he himself had been the first to ascertain that Salvadora Persica was the tree. But he had been surprised to find in the "Flora Medica" of his friend Dr. Lindley, the observation that this tree is supposed to be the Mustard-tree of Scripture. Having only a day or two previously heard from Dr. L. respecting the source of his information, Dr. R. had as yet been unable to trace it out. He, however, presented his paper as a result at which he had arrived, by an independent mode of investigation, and which is, at all events, interesting, as proving that the name Kharjal is applied even in so remote a country as the north-west of India, to the same plant, which in Syria is called Khardal, proving the impossibility of collusion, or the recent application of the latter name to a plant of Palestine, merely to meet the exigencies of the case. Notwithstanding the absence of authentic specimens, the author stated he felt no doubt that Salvadora Persica is the Mustard-tree of Scripture, as it has a small seed which produces a large tree with numerous branches, in which the birds of the air may and do take shelter; that the seed is possessed of the same properties, and is used for the same purposes as Mustard, and has a name, Khardal, of which Sinopi is the true translation, and which, moreover, grows abundantly on the very shores of the sea of Galilee, where our Saviour addressed to the multitude the parable of the Mustard-tree. [We entirely agree with Dr. Royle in this view of the subject, notwithstanding the objections urged against it by Lambert and Don, which appear to us to have no weight.]

New Work on the Vine.—We learn with much pleasure that a descriptive account of an improved method of planting and managing the roots of Grape Vines is about to be published by Mr. Clement Hoare, whose valuable work on the general management of Vines in the open air is so well known. We understand that the author's intention is to make known a new method of planting and managing Vines, so as to give the gardener as perfect a command of the roots as he now has of the branches.

Robinia Uterhartii.—This tree, obtained from a seed planted by M. Uterhart nearly twelve years ago, has a large thick foliage, and its wood is straight and green. Instead of the branches being crooked in the disorderly way of the Robinia, they grow in tiers of whorls, each season of growth producing its shoot and crown of twigs. It appears to be as vigorous as R. pseud-acacia, if not more so. It has no thorns, and produces beautiful bunches of white flowers. M. Uterhart has propagated it, and can now offer some for sale.—*Rev. Hort., Nov.* 1843.—*T.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

In potting stove and other plants, a distinction should be made between the preparation of the composts for permanent woody plants and for those soft-wooded kinds which are annually shaken out of pots. Justicias, Vincas, and some of the Clerodendrons form part of the latter class. After these are done flowering in autumn, they should be close pruned, and left partially dry during winter; in spring the soil should be shaken from their roots, when they are put into small pots to be shifted into larger ones as they advance. The compost for this potting should be made quite fine, in order to let the roots occupy every particle of it in a few months; while the compost for permanent woody plants can hardly be too rough. This distinction ought to be borne in mind a potting-time. A steady heat, not more than 60°, by fire is now essential, as all the plants are in growth; and, except on fine days, little air is necessary at this stage, but keep the atmosphere moist.

Conservatory.—To keep this house now in perfect order, you must go over the plants daily, or at least every other day, and take out such as are beginning to fade. Pick off all dying flowers and leaves, and also distorted flower-buds, or indeed any small or ill arranged flower, which does not look well. Every plant at this season ought to be a gem of its kind, or it is not fit to be brought into the conservatory. Others, however, may be useful for cut flowers to fill glasses, vases, or urns in the drawing rooms. Change the plants in sitting-rooms often, if they are worth preserving afterwards. I give very little air to the conservatory at this season; but for small houses this would not answer so well, and they should have more air, if only to keep down the temperature.

Greenhouse.—Fuchsias represent that class of greenhouse plants which do best to be shaken out of the pots annually; but as the strong varieties of them are gross feeders, you may use a rougher compost for them than is recommended above for stove plants under the same treatment. When potting Heaths, let me urge on you to try the plan of growing them without pots; there is no more trouble or danger in growing the finest Heaths in this way than there is in growing Rhododendron pontieum; and you may remove them from a frame or bed any day in the year, when they are coming into flower, to be brought in doors, or for any other arrangement. Epacrises may be treated in the same way. Both families here are now in the best of health, and many of them are in bloom in the borders of a conservatory wall; others of them, treated as above recommended, give no trouble.

Forcing pits.—Among the many common plants that will force may be placed the old Gazania pavonia and rigens, or Gorteria, as we used to call them in our younger days. Force these exactly as you would Strawberries, and as near the light. Those who force Roses late in spring will now be getting them in for the first time, and must smoke them almost every week. Experiments are now in progress by some of the great Rose-growers, which will settle the question as to whether the Dog rose or the Boursault make the best stocks for forcing on. Repot cuttings and seedlings as soon as they are ready, and keep up a sweet growing temperature of about 70°, and shade every young thing, if it offers to droop under a strong sun.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

The fine weather has come upon us so suddenly, that we appear almost on the verge of summer, before the spring has fairly commenced. All new ground work, such as planting, turfing, &c., must be finished as expeditiously as possible; and as soon as all rubbish has been cleared from the borders, grass, &c., prepare for turning the walk, and making clearer for the season. This, though an operation readily performed, is frequently hurried over and badly executed. A walk, after it has been turned, levelled, and the facing of new gravel laid upon it, should remain in that state three or four days, for the gravel to bleach, and not be rolled until it has had a shower of rain upon it. The utility of this plan is, the gravel becomes washed before it is rolled down, and you have a clean bright walk at all times, instead of one sticking to your feet, and falling into holes in wet weather. This delay causes a little inconvenience while it is about; but it is fully counterbalanced by the excellence of the walks throughout the season.

Reserve Garden.—Birds are very troublesome to newly-germinating seeds, and where it is inconvenient to cover with netting, it will be well to sprinkle the beds with sand made wet with spirits of tar. The transplanting of all autumn-sown annuals should be completed without delay, and also biennials. Prepare a piece of ground for a sowing of the latter, which must be slightly enriched and dug to a good depth.

Shrubberies.—Here the work for the season will be finished except attending to newly-planted shrubs and watering them when necessary. Take care that all newly planted trees are properly staked before they begin to make new roots, and mulch them with short grass occasionally when the lawn is mown.

Pits and Frames.—The bloom of the Hydrangeas, introduced into the forcing-house in January, will now be advancing. If you have any doubt of its being blue, water the plants regularly with water impregnated with alum, to the extent of one ounce to every quart, and keep the plants standing in feeders to prevent the loss of water. The plant may be occasionally sprinkled over head with alum-water. The young plants of this season's propagation will now be fit to pot off. Use the third spit loam from Norwood if you can procure it, which is certain to produce blue flowers. I intend to pot my plants into large 60s, and then plant them into a mass of Norwood loam on a slight hotbed in May. In this way, with a very little trouble, I hope to have unusually fine heads of bloom another season. Brompton Stocks in pots may be planted out, surrounding the wall with rich soil, and spring-flowering ten-week varieties may be left unprotected, so as to prepare them for bedding out about the middle of April.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Auriculas.—These flowers are putting on an improved appearance; still keep them warm at night by mat coverings, and as they are growing fast, they should have a moderate supply of water. I know a very successful Auricula grower, who waters his plants with a decoction of weeds and vegetable refuse, and the luxuriance of his plants is astonishing. *Polyanthuses.*—Last year's seedlings are now throwing up their trusses, and "showing their faces." Those which do not come up to the mark should either be pulled up, or transplanted for border flowers in the shrubbery or elsewhere. *Ranunculuses.*—Seed is now coming up fast; shelter from cutting winds, and if any are rooted out of the soil, which sometimes is the case, they must be carefully re-inserted. Where practicable, the main beds, of named flowers, should be covered with mats, when frost is expected. *Carnations.*—Potting has commenced in many parts of the country, and where the plants have been brought up hardy, the sooner they are out the better; as a precaution, place a slice of Potato between the layers, if two are planted in a pot, so that they may have a chance of avoiding destruction, should a solitary wireworm have escaped you. *Pinks.*—If the directions previously given have been attended to, they will require little else at present. *Pansies.*—The beds may be top dressed with decayed Melon-bed manure, and screened from the prevailing cold wind with Spruce Fir boughs, or other efficient protection. Snails must be trapped, as they begin to be seriously troublesome.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—Having last week recommended the removal of the tan from the sides of the pots if the heat exceeded 95°, I may now add, that the Pine will bear a bottom heat of 95°, or even 100°, without apparent injury, and may even appear to be doing better with that high degree of bottom heat; but I am satisfied that those plants grown in a bottom heat of from 85° to 90° will be the best by the end of the season. It is strength and compactness in the plants that is so desirable, not only for the sake of appearance, but they are more manageable, and produce finer fruit. Suckers in small pots will require watering often when they begin to root freely; admit air daily, if only for half an hour.

Vinery.—Vines started in October will now be changing colour, and should not be syringed; give air daily, excepting during cold, windy weather. The atmosphere should now be drier, to give flavour to the fruit. Continue to stop the laterals till the fruit is quite done swelling, after which they may be allowed to grow at freedom. In the second house the shoulders of some of the bunches may require supporting. Vines lately introduced into houses where the temperature has to be kept high for Pines or other plants, will require much attention to induce all the buds to break. *Bend them more*, just above those buds which are least prominent. Syringe them often, and that this may be done more effectually, keep them along the front of the house, till all the buds have broken.

Peach house.—On trees started in the latter end of November, the fruit will now be showing; and during this process the temperature should be kept very regularly at 55° or 60° by night. Tie in the young shoots often, and continue to stop over strong growths, in order to keep all parts of the tree in an equal state of vigour. If syringing fails to keep down insects, have immediate recourse to fumigating. The late house need have no fire, unless the thermometer fall below 45°.

Fig house. Fig-trees on which the fruit is now ripening will require moderate waterings, on account of the second crop now appearing. Till the first crop is gathered, keep down insects by means of sulphur.

Strawberries.—Bring in another succession of plants according to the demand; let the plants have plenty of air till the fruit is set. Water with liquid manure till the fruit begins to ripen, after which use clean soft water.

Melons.—Those plants put out in February will now require attention to training, watering, and adding fresh soil as the roots appear through the ridges or hills. Give air as early as possible, shutting up with 90° of sun heat. Renew the lining of dung-beds frequently, to prevent any check to the plants; doing the back and front alternately.—*G. F.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Finish planting; all sorts of fruit trees as soon as possible. If deferred later they will suffer greatly, especially if brought from a distance. In such a case the trees, as soon as raised, should have their roots passed through a puddle of loam and water; otherwise the best fibres are dried up before they are inclosed in the package. If nurserymen would see to this, and seedsmen could be brought to act upon the excellent advice of Mr. Forsyth, there would be fewer disappointments.—*Sea Kale* may now be obtained plentifully with little trouble. Where it is wanted early in November, a fresh plantation should be made about this time every year. The ground should be well manured, and deeply trenched. If a stiff clay, add leaf-mould, chalk, sand, or gravel. Sow in patches, or rather use one-year old plants, which will be strong for forcing next season.—*Rhubarb.*—Where this is greatly in demand, prepare the ground as above; divide and plant out old roots; or sow seeds under protection to be planted out in a good situation, encouraged during summer, and lifted for forcing next winter.—*Asparagus.*—A trench may be cut by the sides of a bed in the open ground, and filled with fermenting matter, to forward some to succeed those in frames. It is a good plan to have several beds surrounded with pigeon-holed walls for this purpose, provided with wooden covers. (The same remark will apply to Rhubarb and Sea Kale). Sprinkle all the beds with a little salt repeating the operation at intervals. Stimulants and

manures are most useful in the growing season, when, too often, Asparagus is left to shift for itself.—*R. F.* [In last Calendar, p. 184, 12th line from top—read, "sprung ones," instead of "spring ones."]

VI.—ARBORICULTURE.

Old Woods.—Be careful to go through these before the trees, shrubs, &c. get into leaf, and relieve any young plants that have been kept down, forced to one side, or otherwise injured. Cut away all or a part of whatever injures them, as recommended in former Calendars, and take off any rotten or broken branches.

Coppice.—Great attention should be paid to clearing them of all the saleable and useful produce, as well as of the useless spray from the stools, before the young shoots appear, as they are easily broken off.

Young Plantations.—Continue to forward all the works that are necessary at this season, until they are completed. In recently planted ones now is the best time to hoe among the young plants, in order to clear away all weeds, Grass, &c., before such get firm hold in the ground. It is of the greatest advantage that the first buds and shoots should have a *fair start*; and it saves much labour to clear away the weeds now, as the ground is in a loose state after the frost.

Hedgerows.—Attend to former instructions before the season is too far advanced.

Nursery Work.—The weather still continues unfavourable for many kinds of work that should now be done, but it must be put off until circumstances will admit of it being performed with propriety. The hoeing, weeding, and cleaning of last year's seed-beds, and nursery rows of young plants, &c., should be commenced and finished as soon as possible.—*W. B.*

State of the Weather at Chiswick during the last 18 years, for the ensuing Week ending April 6, 1844.

Mar.	Aver. Highest Temp.	Aver. Lowest Temp.	Mean Temp	No. of Years in which it Rained.	Greatest quantity of Rain.	Prevailing Winds.

March 23d Overcast; cloudy, slight rain at night
24 Overcast; fine; clear and frosty at night
25th Cloudy; boisterous, with rain in torrents; overcast
26th Overcast; rain; fine
27th Very fine throughout
27th Lightly overcast; fine; hazy and mild
28th Fine; very fine, with bright sun; clear and fine at night
Mean temperature of the week, 3 deg. above the average.

Notices to Correspondents.

BOILERS.—*K. L.*—The brick sides to the furnace will most likely cause the fuel to burn better and to keep alight longer, than when the sides consist of the boiler itself. Lowering the position of the fire will not produce any ill effect if there is sufficient thickness of brickwork on each side to prevent the heat from escaping through it. By thus lowering the furnace, you can doubtless increase the area of your fire-bars as much as you please, and the heat will act more powerfully and directly upon the boiler. We shall be glad to hear the result of the change, if you make it.—*A.*

CALCEOLARIAS.—*A Subscriber, Manchester.*—Standishii, Barnes' Landmark, Green's Alba coccinea maxima, Miss Antrobus, Prince Albert, Isabella.*

CAMELLIAS.—*Short.*—A small portion of well-decayed cowdung may be advantageously mixed with the soil for Camellias.‡

DRY-ROT.—*Isle of Wight*—How to destroy this formidable enemy, when it has once attacked timber, no one knows. Your only remedy is, to take out all the infected wood-work, and *burn* it; for thus you will kill the fungus that produces the evil, and all its seeds. Before replacing the timber, you should also rake out all the old mortar that touched it. The new timber should be rendered dry-rot proof by some of the means now patented, such as Sir Wm. Burnett's chloride of zinc, or Mr. Bethell's creosote, or Payne's lime and silicate of potash. Any unprepared timber will probably be again attacked, notwithstanding all the precautions you can take. Be thankful if it does not spread all over the lower part of your house, or even mount to the roof.

FIGS.—*Z.*—Figs are liable to drop their fruit from various causes; but chiefly from their being badly conditioned as regards temperature and water. If the fruit-buds have advanced into the form of young Figs, and then for want of sufficient temperature are allowed to remain stationary for a time, they are apt to drop in consequence, even although a proper heat is afterwards afforded. But supposing a due temperature to be all along maintained, if the juices of the plant have become greatly inspissated from the want of a regular supply of water in sufficient quantity, the young fruits become tough like so many pieces of india rubber. ‖

FRUIT-TREES.—*Strath Isla.*—If you graft your wall-trees which you have cut in with some of the new varieties of Pears, recommended in some recent Numbers of this Paper, you will find they will bear abundantly. Cuttings of Apple trees will no doubt strike by inserting them in a Potato; so they will by inserting them in the soil. Potatoes contain a large proportion of water; and the principal elements of all vegetables likewise enter into their composition. But when decomposition takes place, there is then nothing to hinder these elements from becoming subservient to the vegetating powers of the Apple-tree. ‖——*Anglus.*—You will obtain a supply of fruit much sooner from dwarf than you will from standard trees. There can be no doubt that where the Ribston Pippin does well, many culinary varieties of Apples will succeed as dwarfs. You may plant Dumelow's Seedling, Bedfordshire Foundling, Alfriston, Hawthornden, Royal Russet, Round Winter Nonsuch, and Mère de Ménage. ‖

FUCHSIAS.—*M. W. K.*—Cut them down at once; take care that they have plenty of pot-room, and are thoroughly drained; and dress them with charcoal-refuse steeped in some sort of liquid manure. They will make beautiful plants.——*A Subscriber, Manchester.*—F. Exoniensis, Formosa elegans, Standish's Colossus, Conspicua arborea, splendens, and Epps' Scottish Bride.* ——*Y. M.*—From your description of the properties you require, the following six varieties will most probably suit you:—Epps' Winsertl, Prince of Wales, Standish's Colossus, Candidate and President, and Robusta. Strike a cutting of Corymbiflora after it has formed its buds.*——*W. J.* Venus Victrix.*

GLADIOLI.—*A Subscriber.*—Seeds of the hardy kinds may be sown in the American border, in the second week in April. Whenever the weather is dry, the young plants should be plentifully watered to promote their growth. At the beginning of October, or as soon as the leaves wither, the young bulbs should be taken up and dried; they may be re-planted again at any time, placing them about eight inches under the ground to prevent the frost reaching them, for very severe frosts will destroy them if they are near the surface. The seedlings, if well encouraged, may be expected to flower next year. If the peat is close and rich, it should be mixed with sand, to prevent its cankering them, or causing them to rot by the retention of too much wet in the winter.‡

GRASS-SEEDS.—*Subscriber.*—For permanent pasture, Mr. Lawson, recommends the following:—Anthoxanthum odoratum, 1 lb.; Dactylis glomerata, 8 lbs.; Festuca duriuscula, 1 lb.; F. elatior, 1 lb.; Lolium italicum, 4 lbs.; L. perenne, 8 lbs.; Milium effusum, 1 lb.; Phleum pratense, 1 lb.; Poa nemoralis, 1 lb.; P. sempervirens, 2 lbs.; P. trivialis, 1 lb.; Lotus major, 1 lb.; Trifolium pratense perenne, 2 lbs.; and T. repens, 2 lbs. A plan of a Piggery is given at p. 44 of this year.‡

HOLLIES.—*D. R.*—Holly-seed three years old is not worth sowing when fresh seed can be so easily had. To form a hedge you may either sow it or plant it. A light loamy rich soil is what the Holly likes best.

INSECTS.—*Anon.*—Keep off green-fly with weak gas-water (see p. 697, 1843). Do not use train oil, which can do no good, and certainly does harm.——*Anne.*—After the most diligent search amongst the Moss we could find no living animal—the box having been crushed it had made its escape; we therefore hope to be favoured with another specimen, better secured. *R.*—*A B.*—Cannot you cover your Peach-trees, one at a time, with a thick mat or carpet, fixing it close over the top of the wall and letting it touch the earth at the bottom? By introducing the spout of the fumigating bellows as low down as possible, after being well charged with tobacco-smoke, we are convinced you might get rid of the aphides. The best period will be as soon as you detect them, which you must do by examining the under sides of the young leaves *daily*. Be so good as to send us some infested leaves, and say, as the spring advances, how you have succeeded with the operation, if you can adopt our plan. *R.*——*S. H.*—After the most attentive examination of your Camellia-leaves, I cannot discover a single insect; nevertheless, a few of them seem to have been pierced sometime since by the little Thrips. I regret not being able to assist you in remedying the evil, for the little exotic insect called Thrips can sustain a very great amount of heat. Probably cutting off the leaves most affected will prevent the spreading of the disease. *R*——*J. W. I* of Down, transmitted three pupæ of some fly, saying he failed in procuring more specimens, and desired to know the name, which we cannot ascertain until the insects hatch. We shall feel obliged by his communicating their history, for we know not to what he refers.—*R.*

LAWNS.—*X. Y. Z.*—We said nothing about diluting the gas-water; because we have over and over again stated that it must be lowered by water: with how much we cannot tell, because the gas-water varies in strength. Four of water to one of gas-water will probably do; the stronger, however, the better, if not too strong. It will scorch your grass, but that does not signify; the lawn will soon recover. But from what you say, we should fear that your case is hopeless without thorough drainage, and perhaps burning the upper spit.

MANURES.—*Tyro.*—We can but repeat that as far as we have seen it tried, Potter's guano is a most useful substance; but we have not seen its effects on Onions. It is used at the rate of 3 or 4 cwt. per acre. We would also advise you to try on your Onions the following mixture:—One peck of salt, two pecks of soot, well mixed and left for a few days; then applied as a top-dressing, or lightly forked in. We *hear* of great effects thus produced on the Onion crop.——*Inexperience.*—Both lime, soot, and wood-ashes can be used advantageously in a stiff, clayey garden, especially the two first; but none of them will prove of much service unless the ground is thoroughly drained. On such land farm-yard manure is almost indispensable until it is in a state of perfect tilth, and then it may be dispensed with if other fertilising materials are employed. You will never get good Carrots on heavy land; all such long-rooted plants prefer a deep, light, rich soil.

MIGNONETTE.—557.—If you cannot please your wife how can we hope to be so happy? If we were you, however, we should see whether slate Mignonette boxes of rich soil, exposed to the full sun, and carefully watered, would not satisfy the gentle dame's expectations. We presume that your plants die off in summer; but you are very chary of explanation.

NAMES OF PLANTS.—*R. G*—A Dendrobium, which we do not recognise.——*J. M.*—Gnidia simplex.——*A Reader.*—Erica persoluta alba.——*A.*—Dillwynia cinerascens.‡——*J. L L.*—1, Asterotrichion sidoides; 2, Erica Bowieana; 3, Euphorbia melanthera, Phascum alternifolium.§——*W. Gardner.*—Hypnum ruscifolium. That the filaments which inclose the granules of Equisetum fluviatile are elastic, is known to all who have studied the genus.§——*A Subscriber.*—Burchellia capensis.‡——*Anon.*—Hypnum ruscifolium.§

NAMES OF FRUITS.—*C. C.*—Pears: 1, Beurré Rance; 2, Winter Bon Chrétien. Apples: 3, Cockle Pippin; 4, 11, probably Alfriston; 6, Court of Wick; 12, Pearson's Plate; 13, Green Balsam; 14, Cockpit; 16, Norfolk Beaufin; 17, Kentish Fillbasket; 18, Easter Pippin, or French Crab; 20, Yorkshire Greening; 21, Winter Pearmain.‖——*A. Z.*—1, Chaumontel Pear. Apples: 1, Royal Russet; 2, Blenheim Pippin; 4, Bedfordshire Foundling; 5, Brabant Belle Fleur; 6, Alfriston; 7, London Pippin.‖——*W. H.*—Dumelow's Seedling; 2, Æsopus Spitzenberg.‖——*Kate.*—Your Seedling Apple has become rather mealy; it, however, appears worthy of further trial. ‖

ORANGES.—*M. C. Y.*—One kind will train as well as another, except the dwarf, small-leaved kinds. Neither is there much to say about their appearance as standards, except that the true Oranges form a better foliage than Citrons and Shaddocks; at least that is our taste. No good eatable fruit will be had without plenty of warmth; if properly treated the Malta and common Sweet Orange are as valuable as any. The back of a greenhouse is a bad place for plants. You may, however, grow on it scarlet Pelargoniums, the Cape Plumbago, and Passionflowers, or Cobœa scandens. To the names of shrubs which we have repeatedly given we have really nothing to add. Any of the crimson Callistemons, some of the smaller Acacias, Camellias, and Chorozema varium are almost indispensable to a nice collection.——*Dublin.*—These require a very rich soil. A mixture of turfy rich loam, thoroughly decayed manure, and leaf-mould, in the proportion of two-thirds of the former to one-sixth of each of the latter, is suitable for them. Pelargoniums also like a light rich soil.‡

PANSIES.—*Y. N.*—Brown's Curion, Pearson's Black Prince, Cook's Mulberry Superb, King's Sulphurea elegans, Major's Bridegroom, Thompson's Eclipse.*

PETUNIAS.—*E. B.*—Petunia punctata, Magnifiora, Lady Peel.*

PEACHES AND NECTARINES.—*A Lady Subscriber.*—In order to prevent your Peaches and Nectarines from splitting before they begin to ripen, it is necessary that the border should not be allowed at any time to become too dry; and further, that too much foliage should not be taken off at once; neither should insects be allowed to injure that which is left. If the trees are thus kept in health in dry weather, the fruit will not be affected as you describe when wet sets in. In watering, cold spring water must not be used.‖

PEAR-TREES.—*A Subscriber.*—It is too late in the season for root-pruning; besides, as your two Pear-trees blossom abundantly, it does not appear that they require that operation. A dressing of fresh soil and manure, applied as far as their roots extend, will prove beneficial ‖

POLYANTHUSES—*An Amateur.*—Buck's George 4th, Pearson's Alexander, Clegg's Earl Grey, Hufton's Squire Ray, and Lord Ranclife, Crowshaw's Invincible. Begin to use the liquid manure as the buds begin to swell, about once in a fortnight: take care to keep it from the foliage.*

PELARGONIUMS—*A Subscriber, Manchester.*—Matilda, Witch, Queen of the Fairies, Sir R. Peel, Grand Duke, Lyne's Duke of Cornwall, Rising Sun, Erectum, Nestor, Rhoda, Favourite, Armynta.*——*W. Heath.*—All the flowers in your list we have seen, and recommend you the above 12.*

RHODODENDRONS.—*J. M.*—See p. 88 of this year; for a list of Ornamental Shrubs, see p. 149, 1843.‡

ROSES.—*Amateur.*—Your stocks are covered with young germinating Mosses. They do no harm, but they show that your ground or your air are too wet, and not well ventilated, which should be cured.——*J. B.*—That your China Roses may bloom late, they should be left unpruned until they show their blossom-buds. When these begin to appear you may then prune them as you would do at an earlier season. It is not, however, advisable to leave all the plants to be pruned thus late, as they bloom but sparingly. If some of them are cut in about a fortnight hence, they will flower earlier and much more freely, and the others will come in in succession.‡——*J. M.*—Superphosphate of lime, or Potter's guano, is better for Roses than the substance you mention, of which we have not a good opinion. They may be applied at the rate of a wineglassful to a 24-sized pot. We are not acquainted with the Rose "Beauty of the Prairies."‡

SCARLET GERANIUMS.—*E. B.*—Compacta, Brighton Hero, Frogmore Scarlet, Waterloo, Smith's Emperor, Green's Seedling.*

SEAKALE.—*Guichenet.*—It likes good rich well trenched ground; it will succeed quite well in the situation you mention.‡

TAN.—*H. P.*—Tan will keep up a good bottom heat for a considerable time. It should be used in a moist state, as if it is too dry it will not ferment. When the heat begins to decline the tan should be forked up and mixed with a little fresh material, in order to raise the heat again.‡

TRINIDAD PINES.—*A Subscriber* will find this, and I dare say in perfection, at Cunliffe Lister Kaye's, Esq., Manningham House, near Bradford. I had a small root-sucker from there upwards of three years ago, which fruited with me, but only produced a deformed fruit, from water having accidentally dropped in the heart of the plant in winter. It produced five gills and crown, which are promising plants, but not fruiting here until next year. Mr. Kaye told me himself it was the true Trinidad or Pitch-Lake Pine.—*James Roberts, Eshton Hall.*

WORN-OUT GARDENS.—*Subscriber.*—Can't you get cow-dung? If not, you may employ guano; and as the soil is entirely worn out, it will be better to do so at different periods of the year—say ½ cwt. before cropping, to be thoroughly incorporated with the soil, and then left for a week or two till rains have mixed it; more afterwards, when the crops are up and growing; give them frequent small doses in a liquid form, not over the leaves but between the rows. Mind that your guano is of good quality; a great deal of rubbish is in the market.

VINES.—*Guichenet.*—Inarching may be performed at any time after the Vines have started so far as not to bleed.‡

MISCELLANEOUS.—*Clouden.*—We have been paying 10*d.* per bushel for refuse charcoal; but it is much too dear. We know nothing about faggots. A Hatch load of English bark weighs 45 cwt. Foreign is always sold by the ton. 2 ton 5 cwt. being an English load, therefore if Foreign bark sells at 7*s.* 4*d.* per cwt., English will be 16*l.* 10*s.* per load, and so on. There are many ways of selling bark. In the rough, 50 cwts make a load. A Hatch-load of Oak bark is, the bark stripped from the timber, as felled in April and May, set up to dry in the open air, put under cover, and "hatched"—that is, the moss and outside rough bark are shaved off, and it is chopped into pieces from 2 to 3 in. long; it is then ready to go through the mill in the tan-yard.——*Anon.*—If your Pear-trees bloom and do not fruit you must protect the blossoms.——*B. F.*—Chimonanthus may be propagated from cuttings of the just ripe wood struck in heat under a bell-glass; it is now commonly raised from layers, which, however, root unwillingly; the best way is to get the seeds, which are always found on old plants after a mild winter. It is not particular about soil.——*Farnham.*—Cuttings of the roots of Glycine sinensis may be struck in a little heat; it will also root freely from layers.——*W. F.*—If a lady cannot buy the seeds she wants, there is nothing to be done but to save them herself. No instructions are required, as they will be saved in the usual way. In sending them to New Zealand they must be packed loosely in a coarse canvas bag, which must be suspended in some well-ventilated part of the ship. All European seeds are useful in New Zealand.——*Boulogne.*—There is no objection to a south-east aspect for a small greenhouse. Many plants will thrive very well in it.——*M. C. M.*—Next week; the question is referred to one conversant practically with such questions.——*Argo.*—The cause of the young bulbs of Orchidaceous plants damping, is no doubt owing to their being kept too wet. The suckers may be taken from Musa Cavendishii before it fruits.‡——*Exhibitor* is answered at p. 104 of this year.‡——*P.*—See last vol., pp. 303 and 335, where a full account of the method of burning clay is given, and also at p. 85 of the present year.‡——*Amicus.*—Currants will bear grafting very well.‡——*A Beginner.*—Calico done over with Whitney's composition dries in a few days; the Beechwood is a better Melon than the Green Rock; the plants should be turned out of their pots and planted into the mould in the bed. ‡——*B. D.*—The management of "Couve Tronchuda" is given at p. 120 of this year.‡——*D. G.*—A list of herbaceous plants may be found at p. 681, 1843.‡——*Rum-tbler.*—We do not know it. Walcheren Brocoli is like a good large Cauliflower. It is reported to be hardy, and requires the same treatment as other varieties.‡——*W. J.*—A Pansy for showing should not be less than 1½ inch across.*——*W. J., and W. J. and Co.*—Flowers may be sent packed in tin cases with moist moss.*——*W. J.*—Shape and habit of male, and colour of female, and colour of male parent.*——*W. J.*—The "Florists' Journal."*——*A. R. Z.*—See p. 197, in to-day's Paper.‡

SEEDLING FLORISTS' FLOWERS.

AZALEAS.—*C. M.*—Your seedling presents no improvement either in colour or form, and the petals in the centre are a decided defect.*

CINERARIAS.—*Winton.*—Your seedling is a bold and showy variety of good colour in the specimens received; the edges of the petals curl back, which make them look narrow and irregular; if this fault is not apparent on the growing plant, it is a handsome flower.*——*T. B. Y.*—No. 2 is a flower of good form and substance; the colour with which the petals are tipped, is rather too faint, which gives it a faded appearance, but from its other good properties it makes a desirable variety.*——*E. J. L.*—Rookwood is not worth preserving, on account of its colour being weak, and the petals thin and small.*——Alice is a very good flower in colour, form, and substance, but there are others in cultivation similar to it.*——*Z. Z. Z.*—Formosa elegans, a very lively-looking variety, surpassed by one similar to it in appearance, already in cultivation, named the Dowager Queen. Rotunda, compact and pretty flower, but no improvement, and we have similar varieties to Venus Victrix and Rosea alba, which are both pretty, compact varieties.——*A. B.*—A large and very finely-coloured seedling, of an azure tint; the petals appear rather too long for their substance, as they hang about rather too much; no doubt part of this irregularity arises from the faintness produced by travelling. We are glad to see these splendid colours gradually getting into larger flowers; this specimen measures 1¾ inch in diameter.*

FUCHSIAS.—*Z. Z. Z.*—Alba coccinea. We have the same delicate colours in larger, stouter, and better flowers.*

*** As usual, many communications have been received too late.

IMPORTANT TO AGRICULTURISTS AND OTHERS.

ANALYSES OF SOILS, MANURES, &c., are conducted by Mr. MITCHELL, Analytical Chemist (late of the Royal Polytechnic Institution), No. 8, Victoria Cottages, Hanley Road, Kentish Town.

A vacancy now occurs for one house or outdoor Pupil, for the study of Chemistry as applied to Agriculture. Apply as above.

WE have received from a correspondent who signs himself "Alpha," the following interesting communication, commenting upon our remarks in a late Number of the *Gazette*, on the filthy state of the WATER IN HORSEPONDS:—

"Though I admit the impropriety of allowing the drainage of the yards, or urine from cow-houses and stables, to get into the ponds from which water is supplied to horses and cattle, as demonstrated in your leading article of the 9th inst., yet in establishing the principle thus laid down, an important circumstance seems to have been overlooked. The practice so justly reprobated in that article is impolitic, not only as rendering impure and unwholesome the beverage of the domestic animals, which it is especially important to guard against, but also as allowing this to be done through the agency of matters which are in themselves of great value when properly managed. The conclusion, then, arrived at—that 'there is no case in which food of an organic character in a condition of usefulness for vegetables can be safely administered to animals,' must, we fear, be taken with some grains of allowance. It is well known that the putrefactive process must have proceeded a certain length before animal matters can be rendered available as food for plants; but the circumstance was overlooked by the writer, that a certain class of animals are almost entirely supported by food which is partially and often to a great extent decomposed. That such is a wholesome article of diet I do not mean to assert, yet that it is *decidedly poisonous* is controverted by the circumstance of its being so extensively used. Animal matters constitute the food of the class of animals to which reference is now made, and it may be said the case of such is not analogous to herbivorous animals, which are those referred to in the article in question. With certain exceptions, however, all animal matters are affected by the same laws, and the cases are rare indeed in which any substance proving decidedly poisonous to one class can be partaken of with impunity by another. Instances are not uncommon in which even herbivorous animals have been trained to partake freely of animal food; and although such in a decomposing state might be more injurious to them than to carnivorous animals, yet it does not by any means follow that it would be poisonous. No doubt 'a little leaven added to a batch of dough will spread, and the whole lump acquire the condition of the small quantity added to it,' but the inference drawn from this circumstance, 'that a small quantity of matter, if in a decomposing state, whose elements may be identical with those of a living animal, may yet prove the cause of its death if it be partaken of,' cannot, as it appears to me, be established. The *practice* which the article referred to condemns, is unquestionably deserving of the most severe censure, but the *principle* sought to be established appears to have been too hastily adopted."

We take advantage of this opportunity for recurring to this subject, to direct the attention of our readers to a case bearing directly upon it—a statement of which occurs in the 89th page of Dr. Pereira's work on "Diet." Dr. Pereira writes as follows:—

"At the Nottingham Assizes in July 1836, it was proved at a trial on which I was a witness, that dysentery in an aggravated form was caused in cattle by the use of water contaminated with putrescent vegetable matter, produced by the refuse of a starch manufactory. The fish (perch, gudgeon, pike, roach, and dace), and frogs in the pond through which the brook ran were destroyed. All the animals (cows, calves, horses) which drank of this water became seriously ill, and in 3 years the plaintiff lost 24 cows and 9 calves, all of a disease (dysentery) accompanied by nearly the same symptoms. It was also shown that the animals sometimes refused to drink the water; that the mortality was in proportion to the quantity of starch made at different times, and that subsequently when the putrescent matter was not allowed to pass into the brook . . . . the fish and frogs began to return, and the mortality ceased among the cattle. The symptoms of illness in cows were as follows:—the animals at first got thin, had a rough staring coat, and gave less milk (from two to three quarts less every day); they then became purged, passed blood with the fæces, and at length died emaciated and exhausted. On a *post mortem* examination the intestinal canal throughout its whole length was found inflamed and ulcerated."

Now, here we have proof to the great loss of their owner—proof that cattle (horses, oxen, &c.) are liable to disease and death, from drinking water containing putrescent matter. It must be admitted, from the circumstance mentioned by "Alpha" above, that the proposition of organic matter in a decomposing state being poisonous to animals, is not universally true; the vulture among birds, and many other animals, live almost wholly on carrion and half-rotten animal matters; but, believing this proposition to be true, so far as the farmer is concerned in the matter, and that the putrid state in which many horse-ponds are to be seen is not only disgraceful but dangerous, we were glad to meet with the above passage so entirely corroborating this opinion.

SALT AS A MANURE.

OWING to Mr. Edward Solly's valuable observations on this subject in our Paper of last week, having by an oversight been printed without the author's corrections, we are under the necessity of reprinting two of the paragraphs:—

"When concentrated solutions of common salt and common carbonate of ammonia are mixed at low temperatures, they decompose each other to a considerable extent, and a quantity of bi-carbonate of soda and muriate of ammonia is formed, whilst a portion of ammonia is set free. The bi carbonate of soda being almost insoluble in the solution of muriate of ammonia, may be separated and obtained pure, whilst the muriate of ammonia may be obtained by evaporating the solution and separating it from undecomposed common salt, and free ammonia. But if, in place of separating the two substances, a quantity of water is added, the bi-carbonate of soda dissolves, and the two salts redecompose each other, common salt and carbonate of ammonia being again formed. In the same way, if solutions of carbonate or bi-carbonate of soda be mixed with solution of muriate of ammonia, they mutually decompose each other, and form carbonate of ammonia and common salt.

"It is perfectly true that very strong solutions of bi-carbonate of ammonia and common salt decompose each other, and that common carbonate of ammonia decomposes solution of salt, when carbonic acid is passed through it; but it is equally true that this only holds good when the solutions are concentrated, depending, as it does, on the insolubility of the bi-carbonate of soda, in the solution of muriate of ammonia; if dilute, no such change takes place. When salt is employed as manure it is exposed to the action of a very dilute solution of carbonate of ammonia, for dew and rain-water contain a minute quantity of that salt; under these circumstances it is not to be expected that the salt will be decomposed; for it is not reasonable to compare what takes place in strong solutions in close vessels, with what occurs in the open air with abundance of water. We can only compare the action of rain-water on salt, to the action of very dilute solutions of salt and carbonate of ammonia, and such solutions do not decompose each other. Although chemical facts are certainly against the decomposition of salt by carbonate of ammonia, or the fixation of ammonia by common salt, yet this in no way diminishes the value of salt applied as manure."

There are also the following errata:—

Line 27, from the bottom, *after* nia omit the comma.
" 14 " *for* in organic *read* inorganic.
" 4 " *for* process *read* forces.
" 3 " *after* and *insert* of.

FARM BAILIFFS.

THE national importance of the Commission now acting in Ireland, under the presidency of the Earl of Devon, to inquire into and report upon the relative positions of landlord and tenant, has naturally attracted my attention, and I entertain sanguine expectations that much practical benefit will result to the country in consequence of its investigations. That there is great need of improvement in the social and Agricultural state of Ireland is indisputable; but the question is, By what means the objects sought will be most easily attained? I do not presume to meddle with the political part of the subject, but I may hazard a few observations respecting the Agricultural bearings of the matter. That a considerable impulse will be given to the development of the resources of the country in different ways, I have sanguine expectations; that good landlords will be led to persevere in their humane and rational efforts to ameliorate both the moral and physical condition of their humbler tenantry, and to promote those Agricultural improvements which common sense must show to be conducive also to their own advantage, I fervently hope; and that many bad landlords may be compelled, from the shame of exposure, or the stringency of legislative enactment, to be just, if not generous, to the occupiers of their land, and stimulated to some laudable exertions, through the awakening interest on the subject, I also anticipate. The machinery of our National Agricultural Society, with its numerous auxiliary branches, may be worked with effective power, in combination with other forces, and model schools and farms will contribute in their respective departments. But one of the chief wants—assuming that an extended system of draining, subsoil-ploughing, and spade-trenching, &c., were set in motion—would be that of a sufficiency of intelligent, well-informed, and hard-working Bailiffs, or Stewards, as my countrymen choose to call these dignitaries.

Now, there is a vast difference in England between the sporting-looking bailiff, dressed in a knowing kind of shooting-jacket, mounted on his smart cob, and enjoying a snug salary of from one to two hundred a year, and the plain working bailiff, who in return for his weekly wages of from 12*s.* to 18*s.* a week, and perhaps some extra perquisites of milk, or the keep of a pig and poultry, is thankfully content to take his share in the daily operations of the farm; who, from his own manual acquaintance with the plough and the spade, can not only set a job to a labourer, but can and will show him how to execute it in the neatest and best manner; a man, in short, who considers that his hands, as well as his head, ought to be engaged in the service of his employer. The introduction into Ireland, from time to time, by the land proprietary of first-rate bailiffs from England and Scotland, has been the means of establishing, on numerous demesnes and estates, a highly improved system of Agriculture; and among those bailiffs many admirable men have been found, to whom our country is much indebted for the information they have communicated, and the practice they have exhibited for the imitation of the higher order of our farmers; but since the great majority of Irish landlords and farmers, living by husbandry, cannot afford to pay high salaries, with *et ceteras*, they must either personally superintend their farm-labours (if they know how to do so effectively), or in most instances be content to employ the common working bailiff, whose wages do not greatly exceed those of the labourer.

In referring to the extreme classes of bailiffs, I have passed over some intermediate varieties—very good ones, too—in which efficient and trustworthy men are to be found, who are content with salaries far lower than the maximum point, yet considerably above the wages of the labourer; because the essence of the observations which I would make, is confined (in my own mind, at least), to the humblest description of bailiffs, which I believe to be the most useful, yet the least easily obtainable in Ireland. If men of this low class were a little elevated in their grade of life, and a good deal advanced in acquirements and skill, we have the description of persons critically suited to our ordinary circumstances. A humble person, who is honest, will be more cautious in the first place in the expenditure of his employer's money, more alive to profit, and therefore less disposed to speculative operations than a more consequential sort of personage; and from his personal association with the workmen whom he leads, he will be more likely to acquire their confidence than one much elevated above them; and without a cordial feeling between the confidential manager and the labourer, (I admit, however, that this very confidence may operate very unfavourably, without a sufficient distinction between them) there is danger of those acts of atrocious outrage which so often paralyse the most promising efforts of the patriotic and good of all parties.

But it is difficult to provide in Ireland such a supply of practical and inexpensive native superintendents, as an improved and extended state of her Agriculture may require. I have used the expression native, for, while I most readily acknowledge the superior skill of the imported British bailiff, a feeling of jealousy unfortunately exists, more or less among Irish labourers, against any stranger who may be placed over them. The alterations and improvements which our modes of cultivation so generally call for, would, when suggested and applied by Irish heads and Irish hands, be received and adopted with a cordial interest in their success, instead of being obstructed by that sentiment of distrust which would be entertained to a considerable degree towards what would be designated the innovations of a foreigner. If, then, we hope to effect any great change with an uneducated class of land occupiers, we must begin with soothing their prejudices before we appeal to their reasoning faculties—of which no people possess a greater natural share than my countrymen; but we all know how constantly, even in the most intellectual classes of society, the truth of the old adage is illustrated—

"A man convinced against his will,
Is of the same opinion still."

Now, the difficulty in Ireland—where farming is so defective—is to find the nurseries in which young men can be sufficiently trained, even in practical matters alone. In England there are excellent bailiffs, of every rank to be obtained, from that of the gentleman bailiff (all these matters are relative), who has been highly educated in his profession, to the working manager, who acts in obedience to the orders of the experienced farmer, who knows no superior, and requires no instructor. In Scotland the great farmers, who are their own head bailiffs, could find among some of their hinds, men competent, on emergencies, to work the machinery of a farm—long experience, and familiarity with the details of husbandry, qualify them in a great degree; but in Ireland, our perfect models are very few indeed, whether in agricultural seminaries, or on the private farms of the land proprietary. The proportion of good farmers living by husbandry is small, and it is among them that the most practical bailiffs ought, in altered circumstances, to be looked for and found. The farmer's house and establishment is the true nursery for the class of men in question. Why does the emigrant to Australia, or the Cape of Good Hope, or any great sheep country, seek in Scotland for an intelligent and experienced shepherd? Because sheep-farming, in all its branches, is perfectly understood in that country. The Highland and the Lowland shepherd have their distinct habits and practices, and there is no district in which a suitable shepherd may not be found, fully trained in his vocation by the sheep-farmer in whose service he has been, perhaps, from boyhood.

Again, for illustration.—In the north of Germany, a young man who is to be trained as a bailiff of any class, is required to work on the farm of a practical husbandman for at least three years, as an apprentice, before he can gain admittance into an Agricultural seminary, in which he must pass four years, in every kind of labour; after that servitude he may obtain the situation of the lowest

kind of bailiff on the farm of a land proprietor, or of a farmer who rents his land; or, what is very common, if his means do not permit him to enter one of the admirable Agricultural schools, which have been many years in active operation there, he binds himself—after his first three years' drudgery—on his father's farm, or that of some other person, to a more eminent agriculturist, in a capacity which may be considered that of a principal labourer; for no prudent farmer would think of employing him in a higher rank until he had obtained much more experience, and the scientific information also which the seminaries and model-farms are designed to afford. In short, seven or eight years of patient industry must be passed by these men in Germany before they can presume to expect employment, even in the humblest capacity of superintendence, and many more of practical occupation in this lowest grade, before they can reasonably hope to fill either of the two higher ones. And their expectations as to amount of wages are moderate in a corresponding degree.

These then are, I conceive, the true models for us, and no efforts should be spared by our land proprietors to encourage the discipline of their tenants' sons in this way. The pupils hitherto instructed in our schools have been, for the most part, too much above the peasant class, and filled with exaggerated notions of their own acquirements, and very sublime opinions on the subject of salary,—impressed with the mistaken idea that a smattering of scientific education, neatness of execution in drawing maps, correctness in book-keeping, acuteness in solving problems, and such qualifications, important and essential though they be—are of themselves sufficient qualifications for the situation of land-bailiff, which requires so much experimental knowledge, and so much experience. That numerous model-farms may be so organised, and schools so conducted as to educate the peasantry in a generally useful and practical way, is my anxious wish.—*Martin Doyle.*

ON THE SOIL AND CLIMATE OF THE SHORES OF THE MORAY FRITH.—No. II.

(Continued from page 154.)

Distribution of the Secondary Rocks.—The prevalence of one or other of the members of the great sandstone series now described, influences much the agricultural characters of the different districts. Thus, in Morayshire the upper silicious beds of the deposit preponderate, and hence that district is distinguished for its light, sharp, sandy soils; enriched, however, in very many places by the lime or cornstone formerly alluded to, and by the debris (especially towards the Loch of Spynie and the Laigh or low grounds of Moray) of the lias shale, and by rich modern alluvial deposits.

Protected on the east and north by the high mountains of Banff and Aberdeenshires, and on the west by those of Inverness-shire, which attract and break the great volumes of watery clouds passing over the island from the German and Atlantic Oceans, the district of Moray has always been regarded as possessing a kindly soil and a genial climate; and farther back than the days even of George Buchannan it was described as a favoured spot, and as the granary of Scotland.

In Nairnshire, the silicious beds so greatly predominate and are so near the extensive granitic and primary mountains, intervening between the rivers Nairn and Findhorn, that the whole upper covering of that county consists almost exclusively of a fine loose sand, whence the soil is exceedingly light and porous, and the coating of vegetable mould extremely thin.

As we approach Inverness, the upper and middle schists and freestones of the secondary series, thin out and almost disappear, their line of bearing being prolonged across the Frith into Ross-shire. And accordingly for several miles to the east and west of our Highland metropolis, the fundamental or most characteristic members of the old red sandstone formation are alone to be seen, namely, a chocolate or brick-red compact rubble-stone and huge imbedded masses of a granitic and quartzose conglomerate; the latter presenting themselves chiefly in mural escarpments, or forming the rough summits of the hills. The sandstone penetrates far inland into the Great Glen, composing the beautiful and fertile valley of Urquhart, on the north side of Loch Ness; above which it has been tilted up by the subjacent granite, into the mighty dome of Mealfourvoney, an enormous rounded mass of conglomerate, overhanging a stupendous precipice of granite. The same structure extends around the inner basin of the Moray Frith, called Loch Beauty, along the top of which a beautiful and varied chain of sandstone-hills extends in a curved line; thence deflecting boldly off into Ross-shire, and skirting along the southern flank of the great mountain Ben Nevis. In the fine valleys of the Conon, Strathpeffer, Ferindonald, and Easter Ross, this belt of old red sandstone is covered to a great depth by the soft argillaceous shales of the middle division of the series, so highly charged with bituminous matter as in some few places to contain small inflammable portions, and so much up-heaved and dislocated by the granitic masses below, as to present their strata at every possible angle of inclination, and so broken as to be readily decomposed by the rains and frost. Hence, the surface is beautifully varied and undulating, and the rocks being seldom horizontal, the water easily percolates between their joinings, so that the drainage is good, and the ridges gently sloping, except along the sea-shore, where there are occasional flat fields of rich clayish loam.

The Agricultural zone in Sutherlandshire is confined to a narrow strip along the coast, seldom exceeding a mile in breadth; but it is a beautifully sloped acclivity, rising up along the front of the red sandstone conglomerates, which here rest immediately upon granite, and next the sea there are a few slight remains of the lias and oolitic shales and grit, which anciently extended far out, if not across, the trough of the Moray Frith; and in addition to these, the soil is enriched by the cornstone and other limestones, which are plentiful, especially near Brora and Helmsdale. An enormous protruding mass of granite composing the Ord of Caithness, over which the public road ascends to a height of 1203 ft., interrupts the continuity of the secondary strata; but behind it the old red sandstone and its coarse conglomerate re-appear in the high chain of prominently-marked mountains, which form the boundary betwixt Sutherland and Caithness, and which, observing a north-westerly course, fall into the Northern Ocean at the fishing-station of Port Skerry. From this elevated silicious platform the county of Caithness falls rapidly towards the north and east, composing one enormous undulating inclined plain; the rocks at the further ends dipping into the sea in low horizontal ledges, or cut up by it into long lines of beetling cliffs and headlands. The mass of the Caithness schists has not been disturbed by granitic or trapean action from below, and hence the rocks are nearly horizontal and impervious to water, and the surface is in consequence disfigured by an immense number of stagnant lochs and marshes, and by vast accumulations of peat and bog, rendering the climate cold, and the drainage difficult. Yet even here, though totally devoid of trees and shelter, the persevering industry and intelligence of the proprietors and tenants have reclaimed and brought under the plough a large extent of land, and the fat stock now reared in Caithness are not surpassed in size or beauty in any part of the north of Scotland. These spirited exertions are no doubt much favoured by the circumstance that in Caithness there is an immense development of the mid-calcareous and bituminous shales which are extensively quarried as fine paving-stones, and which everywhere abound with the traces of extinct races of vegetables and fishes; and also that the outer promontories are formed of members of the highest sandstone series (similar to those of Moray and Tarbet Ness in Rossshire), which are more easily cultivated and more clayish in their texture than the hard dark-red beds of the inferior sand-stones next the primitive mountains. Those middle schists of Caithness are likewise prolonged across the Pentland Frith, into the Orkneys, where an exactly similar arrangement exists as on the mainland; there being first a central nucleus of primitive gneiss rocks near Stromness, on which rests a great pavement of old red sandstone, having over it deep beds of calcareous and bituminous shales and grits, and these finally surmounted (especially in the island of Hoy), by an enormous deposit of lighter coloured and variegated freestones, but all banded together into one great formation, by the dissemination throughout the layers from top to bottom, of the same or similar tribes of organic remains. In Orkney also we have the further addition, which is rare in the other districts we have been considering, of extensive dykes and veins of secondary traps and porphyries, the decomposition of which adds considerably to the Agricultural value of the soil.—*G. Anderson, Inverness.*

ON MINERAL AND INORGANIC MANURES.

No. XII.

By Professor Charles Sprengel.

(Continued from page 187.)

On very fertile soils, marl will avail little or nothing, which is easily explained by such soils being already possessed of all mineral substances which are required for luxuriant vegetation. Such a soil requires but good care to yield abundantly, and thus marl is superfluous.

It is often the case that a marly soil is considerably improved by the application of marl. This is easily explained by the former not containing in sufficient quantity all the mineral substances required for vegetation; it may be deficient in gypsum or magnesia, which the other sort may supply it with, and thus make it more fertile. And this fact affords (so it seems to me) an additional proof that these mineral substances are a real food of plants.

In places where marl manure has been used for some time, people have observed that the land which once got marl, cannot be kept any more in a good condition by merely manuring it with dung: it must be marled from time to time, in order to make it yield good crops. On this account people are very cautious in such places not to manure a field with marl, the produce of which has been hitherto satisfactory. Without doubt this phenomenon rests on the fact, that dung does not supply the soil with a sufficient quantity of certain mineral substances, especially not with lime, magnesia, phosphoric, and sulphuric acids. The accuracy, however, of the opinion that a soil is not to be made accustomed to marl, is much to be doubted, because if better crops have repaid twice or thrice the expenses of the one application of marl, why should this process not be repeated?—the expense is repayed by abundant harvests.

Very often the 1st application of marl has a greater effect than the 2d, 3d, or 4th. Nothing is easier to be explained than this; for in a soil never before marled, the lime of the marl will find much of the coal of humus to dissolve, and thus bring powers into play which were hitherto slumbering. Subsequent applications of marl will therefore find less of carbonic humus to dissolve, for a very long time elapses before a new portion will be formed. The greater, therefore, the intervals at which marl is applied, the more striking is the effect. Still, our readers must not believe that we ought to wait the whole interval till the soil again acquires a large amount of coal of humus; on the contrary, it ought to be made a general rule to repeat the marling as soon as the soil is deficient in those mineral substances with which the marl at our command may supply it. It is easy to ascertain, by the condition of the crops, whether the soil is thus deficient. There is certainly a means of obtaining from every marling a similar good effect, viz, to manure the soil not only with dung, but at times also with mould or vegetable earth, as it will thereby receive back that humus which the last marling has decomposed. Large quantities, however, of this mould are thus required; because, if the soil previously contained only 3 per cent. of humus, this will amount, in a furrow-slice six inches deep, to 40,000 lbs. in the Magdeburg acre of land; and it is impossible (even if it were to be useful in other respects), to supply the soil by dung alone with such a large amount of humus, 20,000 lbs. of dung yielding scarcely 2000 lbs. of humus. It is on this account that it is so difficult to replace the humus once taken from the soil, and the greatest caution is therefore to be taken as well in the application of marl as of lime, for a hundred years may not suffice to remedy what has been spoiled in a dozen.

It has been further observed, that the better the crops succeed after the application of marl, the sooner the exhaustion of the soil takes place. In order to explain this phenomenon we must observe, that a greater mass of vegetation encroaches upon a greater amount of the mineral substances of the marl. The weight of any crop is always in a direct proportion with the weight of the mineral substances which the soil has yielded towards its development; because in 1000 lbs. of Clover there is always twice as much potash, phosphate of lime, sulphuric acid, &c., as in 500 lbs. Even the carbon of the soil is more encroached upon by 1000 lbs. of Clover than by 500 lbs., and if we observe that after luxuriant Clover, corn will grow better than after one of a poor extraction, this results from the former always leaving a larger weight of roots behind in the soil. As it may well be supposed that by marl more coal of humus may be decomposed and converted into vegetable nourishment than the plants may be able to consume at the time, we must take care not to use too much of this mineral, as that humus which has been decomposed and is not used by the plants, is liable to loss by volatilisation and extraction by water, and the coal of humus is to be considered as a treasure not to be drawn upon but by necessity. It is, indeed, one of the most important substances for vegetation, because through its instrumentality Nature has guarded plants against being deficient in nourishment; in it many nutritive substances for plants are stored up. Notwithstanding this, however, it is often considered as a useless ingredient of the soil, and every one tries to get it decomposed as fast as he can. It is the coal of humus which chiefly heats the soil, by its detention of the rays of the sun; it is this, also, which loosens the soil, and supplies it with moisture, as it possesses great hydroscopic power: its value is rarely sufficiently appreciated. If, however, marl is used with discretion, we never need apprehend that the soil will be deprived of its strength, because, even if the plants growing more luxuriantly should deprive it of more mineral substances, yet the greater amount of vegetable matter will furnish us with the means to prepare more manure, and we can thereby return what has been taken from the soil.

(To be continued.)

MECHANICS AS APPLIED TO AGRICULTURE.

[The following is an abstract of a lecture on this subject delivered by Mr. Cottam, on March 8th, at the Royal Institution—the President, Lord Prudhoe, in the chair.]

To state that within the last few years the character of English Agriculture has materially changed is, perhaps, superfluous. The great problem that we now attempt to solve is, how to draw from the land the greatest possible product at the least possible expense; and this not for one year or for two, but for many years in succession. In this consists Agriculture as an art. Subordinate to this, however, each in different degrees, but all more or less subordinate, is a long range of subsidiary sciences. It is the recognition of the importance of these subsidiary sciences wherein consists the improved character of the Agriculture of the days we are living in. It is not enough at the present time to cultivate our lands as either empirical experimenters or as the indolent followers of established practices. Of science, in more than one shape, we call in the aid and assistance. The value of the particular science of chemistry, and its bearings upon the all-important subject of artificial fertilisation and manures need scarcely be pointed out. The labours, first of Davy, afterwards of Liebig, have not been expended in vain. The importation even of foreign manures has become a large element of English commerce. We fetch bones from the continent of Europe, and guano from the islands of America; and doubtless in this department of traffic new sources will be discovered and made available. In the desert between Egypt and Syria the bones of unnumbered horses and camels that have whitened and accumulated during the lapse of centuries afford a supply that, according to the report of eye-witnesses, is inexhaustible. Over and above the importance of geology in all matters of drainage, that science has discovered the manures that chemistry has indicated. Liebig had scarcely shown the importance of the phosphates when Professor Buckland indicated an indefinite supply in those remarkable fossils called coprolites, which analysis has shown to be rich in the phosphate of lime. Beds of coprolite underlie whole areas of the counties of Huntingdon, Bedford, and Cambridge, which a subsoil plough could reach, and may be brought to the surface and exposed to the decomposing influence of the atmosphere. In the Spanish province of Estremadura, a whole stratum of phosphated rock has been discovered. A part equally conspicuous with that of chemistry and geology,

is played by the sciences of botany, zoology, and physiology. These determine the choice of seed; the culture of artificial grasses; the value of stock; merits or demerits of particular breeds of cattle; the methods of feeding and fattening; and thus, in a manner too direct to be overlooked, influence the great question of economical agricultural production. The points of agriculture that bring us in contact with the exact mathematical sciences, and with natural philosophy, are numerous, varied, and dissimilar. The method by which we lighten the draught of plough or carriage, and the plan by which we convert by means of drainage whole areas of unproductive moss into fertile soil, are alike subject to the exact calculations of mathematics, and alike involve the science of the mechanical philosopher, the skill of the engineer, and the practical ingenuity of the mechanist. It is upon the latter subject that I have this evening the honour of addressing you; and I feel certain that in the points which I shall attempt to illustrate, viz., the Improvement in Agricultural Implements and Machinery, we have not only a department of agriculture far from unimportant, but also one wherein the progress made in late years is quite on a par with the advancement made in the other sciences, applicable and subsidiary to the art of agricultural production. The agricultural engineer has to contend against difficulties unknown to all other branches in the whole range of manufactures. In manufactures you have everything at command. If you require a high temperature to spin cotton in, it is easily obtained; if a moderate one for silk, it is as easily to be had. If you require a very moist one for flax, or as it is found now to be better spun in water, it is easily accomplished. If a difficulty is met with, once removed, it is wholly removed. Not so with Agriculture: in this we must take wet or dry, hot or cold, as the season may happen to be.

(To be continued.)

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. XII.

(Continued from p. 186.)

I HAVE stated above that the carbon of plants is derived from the atmosphere. This is the opinion of Liebig, who confines the use of humus (which by its decomposition sets free carbonic acid), to the young plant, before its leaves are sufficiently matured to absorb it from the atmosphere. But I do not think this question by any means settled; and we yet want a series of sound experiments to decide the point.

The effect produced by carbonised manures, such as rotten straw, on the crop of Corn, or on tubers, as Mangold Wurtzel, Potatoes, and Turnips, is sufficiently striking to throw a strong doubt upon such effect being entirely due to the ammonia and inorganic constituents. If the amount of starch in Wheat were found the same in a crop manured with urine, and that treated with rotten straw, the inference would be just—*cæteris paribus*—that the carbon of this starch was derived from the atmosphere. If the difference were in favour of the rotten straw, it would be fair and rational to assume this as the source, and to conclude the opinion of Liebig to be erroneous. But Liebig affirms that if we supply a plant with nitrogen we enable it to attract more carbon from the atmosphere.* If this opinion is correct, we may fairly arrange the food of plants into two classes, direct and indirect nutrients. Thus, if, according to the opinion of Liebig, we supply a plant with a certain amount of nitrogen, this nitrogen will fix a certain amount of carbon in the organism of the plant. Every 15 parts of nitrogen requires 55 parts of carbon to convert it into gluten or albumen, which according to the above supposition is drained from the atmosphere, and thus the nitrogen becomes the indirect means of supplying the plant with carbon. If this fact be established by sound experiment, it is very important, because it adds another element to those supplied by the urine—it would render the use of straw-manure less necessary in soils abundant with the inorganic constituents of plants, and infinitely increase the already great value of urine as a manure.

But Liebig's view of the use of nitrogen as a fixer of carbon, it is clear, can only apply to azotised crops. In Turnips and Potatoes the proportion of nitrogen to the carbon is as 1 to 10 or 15. Here the carbon is in much greater proportion than could have been produced by the union of nitrogen with it to form gluten or albumen. Whence, then, is the excess of carbon? If we increase the weight of a Turnip by a pound, by adding rotten straw and dung manure, and we find the increased amount of nitrogen insufficient to fix the additional carbon, we naturally infer that it must have derived it from the decomposition of the manure. But this and other important questions can only be decided by experiment—mere inferences may lead us to inquire, but they are useless in application to practice, unless confirmed by experiment.

What I have just said, however, will prepare us for considering a very important point, which has hitherto been much neglected in performing these experiments,—I mean the necessity of adapting the manure tried to the crop grown. Thus, if Liebig's assertion is right, that plants derive their carbon from the atmosphere, and that a supply of nitrogen increases their power of absorbing it to the extent necessary to form albumen; then if we apply urine or guano to Turnips, or Potatoes, or Beet, much of the azote must be lost to the crop, which only contains one part of albumen to every nine of unazotised matter; whereas, if we apply the same manure to Beans or Peas, one part of albumen is required for every two of unazotised food! It thus requires no illustration to prove that to test the value of urine or guano as a manure, it should be tried upon Beans, Peas, Wheat, or Barley. I do not wish to be misunderstood. I do not mean that guano or urine will have no effect upon the tubers, but that different results will be obtained if they are applied to the Corn crops; that an azotised crop is the proper one to test the real value of an azotised manure. The weight of grain is increased by the deposition of gluten; that of the Turnip, by sugar or starch. In the former case, the action of the azotes may be said to be almost unlimited; in the latter, it is confined within certain limits.

But it may be asked, Does not an azotised manure, or any other manure, act as a stimulant to the roots of plants, and thus increase their growth? The question is important, and deserves inquiry; for it is one upon which the minds of nine out of ten are made up in the affirmative. Our notions of a stimulant are formed from the effect produced by certain substances upon the nervous and circulating systems of animals. If a man drinks a glass of brandy, it extricates nervous influence in the heart and arteries, and produces increased action in them. Thinking of this, we are apt to assume that a strong application of manure has a stimulating effect upon plants. But, whatever the effect of this upon plants may be, we must entirely reject the notion of its being similar to that upon animals. In the first place, plants are destitute of a nervous system; and I know of no proof that their circulating fluid—the sap—is increased in the velocity of its ascent or descent by the application of manure. Does it cause the roots to penetrate further into the soil in search of proper food, and thus act as a stimulus to them? We are again met by the same difficulty—the want of a nervous system; but we have a still greater objection to this notion in the statement of Liebig, that the carbon of plants is derived from the atmosphere, and therefore the search of the roots, to which they are assumed to be stimulated, would be useless. If, however, we carefully observe the action of manures, we shall not fail to reject entirely the notion of stimulants, and attribute their effect to the simple supply of abundance of food by which their rapid growth and increase in bulk is occasioned. Thus, nitrate of soda, or potash, will give a green, rank appearance to the blades of Corn. We have shown the alkali to be one of the constituents of the stalk; and being supplied with abundance of material, an increased size of the fabric results. The green colour is a well-known effect of the addition of alkali to vegetable matter, as every cook who adds soda or potash to the water in which she boils her Peas or Kidney-beans well knows.

Again, the effect of stimulants is not that of increasing the bulk of the animal. Some men, who drink hard, certainly accumulate fat, but this is not the result of eating more, for the converse is generally the case: it is caused by the elements of the alcoholic fluid producing a superabundance of carbon in the system, which is converted into, and deposited as fat. But if a stimulant, properly so called, were applied to the roots of plants, it would destroy their vitality, and the plant would die.

We must, then, altogether reject the notion of any manure or application to plants acting as a stimulant. The effect of strong manures in making plants grow is owing to the supply of abundance of food. Potash will not make the roots take up azote, nor azote potash; they are each taken up by the roots, and appropriated to the peculiar part of the plant they are destined to form or increase, and azote can only enable a plant to fix as much carbon as is necessary to form gluten, albumen, or fibrine. This digression will be excused, as the subject is very important in deciding the *modus operandi* of manures.

Having said so much about the theory, let me now make some remarks upon the confirmation which the principles I have advocated receive from the observations and experiments of others.—*C. R. Brer, Stowmarket.*

(To be continued.)

* Agricultural Chemistry, p. 189.

Home Correspondence.

Transplanting Swedes.—I attended the Show of the Royal Agricultural Society at Liverpool, and the evening after the great dinner joined a party of farmers at the Angel Hotel, and was induced, after discussing various subjects, to detail to them my practice and success in transplanting Swedes, which was listened to with great attention, and one of the party said—"I have travelled many miles from the north to this great meeting; and I thought I should return home without 'gaining a wrinkle;' but I discover that what you, Sir, have said about transplanting Swedes, is the best information I have obtained." Several expressed themselves to the same effect, and requested me to repeat the subject. The recollection of that circumstance, and the uniform success that has attended my plan, induces me to send it to you for publication. The land I have always appropriated to the purpose has been that which has borne a crop of winter Vetches, and which is in general cleared by the middle of July. It must be prepared by ploughing, rolling, &c. &c., as it would be for seed; also by cutting out the ridges, laying in the manure, and spreading it, and all is ready for planting. The plants having been drawn from the seed drills, and placed at convenient distances for the planters (women, girls, or boys), the length of the land is to be divided into as many equal distances as you have planters, the ploughman then turns one furrow on the manure, and the planting begins. The row finished, the plough returns, and, with a lighter furrow covers the plants. Each planter should be directed to follow the plough, watch the covering of the plants he has laid down, draw out any plant too much covered, or cover any displaced by the feet of the horse. Whilst the plough is returning in the next furrow, the planters will supply themselves with plants, and take their places as before, to be ready to lay them down so soon as the plough has passed. In windy weather, and when the plants are large, it is better to direct the planters to lay a handful of soil on the roots to prevent their being displaced. The planters must be urged to quickness, &c.; and those who may be induced to try this plan will be surprised how very fast the work will be performed; and when a sufficient number of hands can be procured, two or more sets can be employed in the same field. The after-work is very little—drawing the soil from top to root, from between the plants, and cutting up the few weeds that may appear, is all that is necessary. I planted Swedes one remarkably hot and dry summer, when the soil was "as dry as the dust on the turnpike-road." The leaves were in two or three days so completely dried, that they could be rubbed to powder. However, two-thirds of them grew, and produced a fair crop. The Swede plant is not easily killed; and I prefer the soil rather dry than otherwise for transplanting. The advantages are these—you are sure of a crop—the expense is less—and the weight per acre is greater than that raised from seed. My seed-crop last year was so much destroyed by the fly, that I could not draw a plant further than to fill up vacancies, and I was "put to my shifts" to plant my ground. I purchased 10,000 plants, at 1*s.* per 1000, of a gardener, whose foreman had sown Swede instead of Cabbage seed. They were seven or eight inches long, and like sticks, and queerly-shaped bulbs they made; but the weight per acre was much greater than that from the seed crop, and would have surprised anybody. I am so thoroughly convinced that a more equal and better crop can be raised by transplanting, that I fully intend to transplant my main crop, and shall sow seed to grow plants the first week in May. I hope that some of those gentlemen who may be induced to try my plan will give the result through your Paper next autumn.—*W. S.*

Yew poisonous to Animals.—Seeing an article on this subject in your last *Gazette*, I send you the following extract bearing upon it from Anderson's "Rural Economy," published in 1798. No plant in Britain is a more certain poison to domestic graminivorous quadrupeds than the common Yew-tree, and many are the instances of cattle, horses, and sheep being killed, which have accidentally tasted of its leaves and young twigs. Yet it is a very surprising fact that in the province of Hesse, in Germany, where hedges of this tree abound, the peasants feed their cattle through the winter with its tender shoots, which they find a very excellent and nourishing food, at a season of the year when other sorts of succulent food cannot be easily obtained. Prof. Wiborg, of Copenhagen, hearing of this, was at first inclined to think that the common opinion that the Yew-tree is a poison to animals was unfounded; but experiments soon satisfied him, to his cost, that it certainly was so. He then suspected that the tree called by that name in Hesse must be something else than the common Yew, and he determined to take a journey thither to ascertain the fact. He found it was the common Yew-tree, and by experiments he then made he also found that it proved equally poisonous to beasts in Hesse as it had been in Denmark. He then suspected that he had been misinformed in regard to its being there used as a food for beasts in winter; but here also he was soon satisfied he had been told only the truth, as the peasants readily allowed that they used it for that purpose every year, and that it made a valuable part of their winter provender. Surprised at these facts, he then inquired what were the means they employed to destroy its poisonous quality; but to this they could give him no satisfactory answer. All they knew of the matter was that they found it necessary, at the beginning of each season, to use it sparingly at first, and to give it to the beasts along with their other food; that they gradually increased the proportion of Yew twigs, which at last came to be a principal part of their food, but that they never kept their beasts entirely on that food alone. At the first he suspected that in this case, as is experienced by man in regard to opium, the animal frame gradually became habituated to this drug, so as to admit of its being taken in much larger doses, in time, with safety, than could have been practicable at the beginning; and it seemed to him probable that its deleterious effects were counteracted merely by the operation upon the animal economy of other food that was administered along with it. Convinced of this, he ventured to give at once to a horse eight ounces of green Yew twigs, (which he had previously repeatedly found was sufficient to kill any horse, when given by itself,) chopped small and mixed among 20 ounces of Oats. This mixture the horse readily ate up at the first, nor did the smallest symptoms of any disorder appear. This experiment he so often repeated as fully to ascertain the fact that, when administered in this manner, the Yew-tree was perfectly innoxious, and that it is solely to the circumstance of its being always administered along with some kind of dry food in Hesse, that it proves there salutary instead of hurtful.—*M. S.*

Gorse.—"Vijorn's" remarks on preparing Gorse as food for cattle, remind me that when a boy we used it as food for horses (in Forfarshire); and as at that time machines for those purposes were not so common, the means used was to place the Gorse on the barn floor, and thresh it well with the flail; and this was found to answer well, and the cattle to improve by its use. As every one may not be in possession of a machine for bruising it, perhaps it may be useful to know that the above method will answer until such time as they get a better.—*A. C.*

Allotment System, and Liquid Manure.—I beg to submit to the judgment of your readers a few observations, in order to draw public attention to the importance of this subject; and in doing so, I shall simply detail my own practice, and take especial care to advance no opinions which I have not tested by long experience. To the labourer who keeps a pig in the sty, I would say, the inner and outer yards should have a paved bottom, with a

gentle slope to one point, at which point a hole should be made, if the subsoil be an impervious clay; or, what is better, a tar-barrel, or something of that sort, should be inserted in the ground, with its top on a level with the surface, and covered with a lid of some sort. Into this hole, or tub, all the drainings will run; and into it should daily be poured, when there is any, all the waste wash, soap-suds, &c., that the cottager's wife can command. Whenever the hole, or tub, is full, it must be emptied with an old bucket, or watering-pot, not used for other purposes, and carried into the garden, either to the different crops, or when they do not require it, to some vacant place before cropping, for which it will be an excellent preparation. It may be applied with great advantage to the roots of Gooseberry, Currant, Raspberry, or other fruit-trees, not merely to the stems, but at some distance from them. I dare say it is often out of the power of many respectable labourers to procure a tar-barrel. If his own resources be inadequate, let him state his case and his intentions to his landlord, or neighbours, and they, one would hope, would readily aid him in such a laudable object. To the owner of a cow, or a horse, &c., and who is generally the occupier of more or less Grass-land, this subject is also important. In this case there will probably be a stable or cow-house, and, if of a good size, the tar-barrel will, in my opinion, make a cistern large enough for a cottager who keeps two cows, or a cow, horse, and pig. If he also have a fold-yard, the draining from that, as well as from the pigsty and eaves of his house, should all run into it. The waste of the house, too, must help to fill it. The cottager must also see that all the dung his cattle drop in the field or near his house is carefully collected, and put into the tub, and stirred well up before using it. I believe that to be the best way of using out-door manure. Or he may collect it often, and throw it upon his manure-heap at his house; or do with it as recommended in a previous article. In disposing of the liquid the cottager must attend to his Grass-land; and if it be close to his house—as it always ought to be—he will easily apply it by means of a bucket or watering-pot, which should be emptied all at once with a jerk, to spread it, taking care to select the barest places on which to apply it. Nor must he forget the claims of his garden. I have been in the habit of applying this liquid manure at all seasons of the year. I have manured, the last dry summer, a great deal of close grazed land in this manner with the best effects, and I never observed any burning or scalding from it when applied in any state, or at any time. In a very short time after applying it the herbage springs up luxuriantly, and is greedily eaten by cows, horses, and pigs. This plan of managing liquid manure is much better for the cottager and small occupier of land than catching the drainings, and returning them again upon the dung or compost heaps, as recommended by some popular writers. The benefit is immediate, sure, and without waste.—*W. Billington, Oswestry.*

Foot-rot in Sheep.—Caution.—While your readers' attention has been turned to the disease of foot-rot in sheep, when either house-fed or kept in a damp situation for any length of time, I would beg to offer a caution to shepherds, and others looking after the animals, when so affected. If any of the matter of foot-rot come in contact with a sore or abraded surface on the hand or other part of the body of a person tending the animal, it is apt to produce a violent inflammation and rapid mortification of the part,—a disease termed by medical men gangrenous inflammation. A shepherd in this neighbourhood nearly lost his life from this cause lately, and the disease was only arrested by burning out the whole affected part. The mode of treating sheep when labouring under foot-rot here, is to clean the parts diseased, and apply the strongest nitrous acid carefully with a straw, or glass rod. This very soon conquers the disease. Those animals affected with the complaint should be immediately separated from the rest of the flock, as treading in the same footsteps will spread the disease from the tainted to the free.—*J. L., Newburgh.*

Fieldbeet v. *Mangel Wurzel*, alias *Mangold Wurtzel.*—In the last Number of the *Agricultural Gazette*, your correspondent "S." comments upon "the barbarous mode often adopted of spelling this name Mangold Wurtzel," and pretends to show that it should be called Mangel Wurzel. This is decidedly exchanging bad for worse, as will be seen from the following explanation:—The word Mangold signifies Beet, and is applied in Germany to Leaf-beet (Beta cicla, L.), which is grown in gardens for the sake of its leaf-stalks, which are eaten like Seakale. Wurtzel, or more correctly, Wurzel, signifies root; Mangold Wurzel, therefore, is literally Beetroot, a name given to a variety of Beta vulgaris, L., of which the Field-beet and Sugar-beet are also varieties. As for Mangel Wurzel, which literally means root of scarcity or deficiency, it is ridiculous to suppose that this root should be abundant when other crops have failed. If your correspondent "S." is not content with the proper name of Fieldbeet (however generally adopted that of Mangel Wurzel may be), and if he should have a predilection for foreign names, then let him import those of "Runkelrübe," "Knollrübe," or "Dickrübe," by which the Fieldbeet really goes in Germany; as for that of Mangel Wurzel, he may in vain ask for it in the seed-shops on the Continent. How the word Mangel Wurzel came to be received in English I am not prepared to say, unless we allow the usual dose of distortion in adopting foreign names. With regard to consulting dictionaries for the proper translation of technical or scientific terms, the following example will show how far such authorities can be depended upon:—The word Melocoton is applied in Spanish to a yellow-fleshed cling-stone Peach; in some fruit-catalogues I find it changed to Mélecoton and Mallacoton; in an English and German dictionary, I find the original pure Melocoton, but for an explanation I must turn over to Melicotony, where I see it translated "a Quince," "a Peach." Not satisfied with this information, I refer to a Spanish and English dictionary, where, in the mean time, it had grown into "a Peach-tree ingrafted in a Quince-tree!"—*A German.* [Melocoton is evidently the Malum cotoneum of Pliny, which was our Quince, whence the Melacotogna of the Italians; it has been applied to the woolly clingstone Peaches on account of their resemblance to Quinces.]

Remarkable Heifer.—Mr. Matthew Bailey, of King's Cliffe, Northamptonshire, killed, on the 7th of March, a Short-horn heifer, in which the left kidney with the fat attached to it weighed six stone and a half, 14 lbs. to the stone. The suet was extremely compact and white, and of the very best quality, and there was not the slightest adhesion to any of the adjacent parts, or the least appearance of disease. The heifer had been in the field without any hay during the winter, till the middle of January, when it was taken up and fed with oilcake and hay by Mr. Boughton, of Fotheringhay. The weight of fat on the kidney is very extraordinary, especially in a beast which had been fed so short a time, and weighed only 58 stone. The other kidney had the usual quantity of fat upon it, and the beast altogether was in excellent condition.—*M. J. Berkley.*

Manure.—The necessity of bringing land, which now lies fallow, into cultivation, becomes daily more pressing as the population increases, and the demand for food is greater. The reason for allowing arable land to remain unproductive, is the want of manure. Cropping the soil where it is well fed is an advantage, as it tends to keep it clean and healthy; whereas the best fallows are often, during part of the year, covered with weeds, which require sustenance, and are stealing that which would enrich grain, and by so doing impoverish the land. To obtain a cheap and lasting manure should be the grand object of the landlords and farmers. The greatest part of household refuse in towns and villages is now thrown away (forming the very essence of food for vegetation), all drains are being led into some neighbouring stream, by which thousands of pounds' worth of valuable dressing is carried into the sea, and lost to the present inhabitants of the country. The fertilising power of night-soil is extraordinary, being too strong for any plant excepting Tobacco, for which it is much used in France. The question arises, How can the off-scourings of towns, &c. be judiciously collected for beneficial use? It is not perhaps possible to save the whole drainage of a populous district, in consequence of the manure being in a liquid state; yet by constructing a succession of reservoirs, of a certain depth, the fluid passing through these would deposit a valuable portion of matter in each; and they might be so connected that any one might be cut off from the rest, to admit of the solid substance settled on the bottom being cleared out for agricultural purposes. These receptacles would answer also for liquid manure, which might be pumped out for watering the land. On examining into the results of experiments tried with various composts, it appears that, in almost every instance, good farm-yard dung carries the palm in giving heavy crops, and afterwards in essentially benefiting the soil more than what may be termed the new manures. Such being the case, it is most important not to discard that which is even more powerful than the common muck-heap.—*Falcon.*

Turnip Seed.—As the following method of treating Turnip seed has proved very successful in preventing the ravages of the flea, I have taken the liberty of sending it to you. A day or two before sowing, put the seed into a sieve and tub of clean water, and rub it quite clean through the sieve, changing the water once or twice; dry it in the sun under a wall or glass, or before a fire. A little flour of brimstone may be mixed with the seed while still damp. If the egg of the Turnip flea is committed to the soil with the seed, this is an effectual preventive.—*A. B.*

Mr. Booth, in the article "Experiments with Manures," states that "the soil is a free light loam, averaging about a foot in depth on a yellow clayey subsoil, interspersed with spar." Perhaps it would have been more satisfactory to the readers of the *Chronicle* if he had told them what sort of spar it was—whether it was calcareous spar—carbonate of lime, gypsum—sulphate of lime, or heavy spar—sulphate of barytes, &c. If it was either of the latter—barytes perhaps—it might have some effect upon the other sulphates which he used.—*Peter Mackenzie.*

British Guano.—I have just received a bag of sea-birds' dung from the Flamborough Cliffs, on the Yorkshire coast; it is like the dark guano. There are recesses in the rocks, where it is a great many feet deep, where this was got; there were a great many tons got up last autumn by the farmers, who were going to try experiments with it, but the time has not come to know the results. If you would like to see a little of it, I will send it you. As there are so many different opinions about guano, you would have a chance of comparing the two together, as we know this to be the real dung of sea-birds.—*A Yorkshire Subscriber.* [We should be glad not only of a specimen, but of the results of its application when they are known.]

Rooks.—Your correspondent "S." suggests that sportsmen should shoot these birds for the purpose of examining their crops, to ascertain the good or evil which they do. I have frequently requested farmers to examine the crops of every Rook which they cause to be killed; some of them having done so, have declared that they would never destroy another. These trials, however, may not be fully decisive, because they will generally be made when the grain is most exposed, whereas the birds must feed all the year. Besides, we have a simple remedy against any evil which they may do, by watching at seed time, or near harvest, when corn is laid. I believe it will be found that they will never touch corn when they can procure grubs, &c.; that is, in moist weather. Similar observations will show that pigeons do not so much harm as many suppose. They will sometimes be found full of Charlock seed, &c. when the farmer shoots them for destroying his Barley; and the grain which they may eat occasionally is only what is left on the surface (and would come to very little), as they cannot move the ground.—*B. W.*

Moles.—I recollect seeing many years ago, that the tenants of the Duke of Buccleuch had resolved to destroy no more of these hard-working animals. Can you tell whether they persevered in their experiment—and with what success? In high farming, without summer fallows, we should take every precaution against destroying our best allies. At least, let us try to distinguish friends from foes.—*B. W.* [Can any one answer "B. W.'s" question?]

Nettles as a Fodder for Cattle.—Some of your readers will perhaps think we are jesting when we assure them that such a common weed as the Nettle may be used with advantage as a green and dry fodder for their cattle. It is much used on the Continent, particularly in Holland, where whole fields are cultivated for this purpose; it is cut five or six times a year. In Holland the horse-dealers give the seeds to their horses to make them brisk, and to give them a fine skin; the roots are also extensively used for dyeing yellow. Nettles either eaten green or dried are considered by the farmers of the Continent to promote the fat of horned cattle, as also sheep and pigs, and the seeds when mixed with Oats are considered excellent for hard-working horses; it is a good food for poultry, and the fibres are manufactured into cordage. In our own country the tender shoots are often used as a pot-herb, and they are said to relieve consumption; it is also much used on the Continent as a salad, for which purpose it is sometimes forced in gardens, when other salads are scarce. If any of your correspondents have made use of this plant as above, we shall feel obliged for the results through your pages.—*J. McI., Hillsborough.*

Steeping Seeds.—I have been not a little amused on perusing the article on Steeping of Seeds, by the Rev. Mr. Huxtable, in page 170 of the *Agricultural Gazette.* It is to be expected, however, that failures will happen on a first trial of the process, as there are many contingencies that will affect the success or failure of it. In many instances, at first, I destroyed the vitality of seeds in endeavouring to ascertain the precise limits of quantity, strength of solution, &c., that are necessary to obtain the maximum of fertilising effect. I expect, however, if in health during the course of this spring and summer, to do so; but, as yet, I must confess that I have not satisfied myself on these points, although my experiments have in this respect been eminently successful. Being the first, in this country at least, who has turned his attention to this subject, I have entered a *caveat* for England, Scotland, and Ireland, in order to secure to myself the right of manufacture, for sale, of all fertilising solutions from salts of ammonia, soda, potass, alumina, silica, magnesia, liquefied guano, &c.; but, at the same time, I should be very glad to hear of other experimenters among Agriculturists who are trying by similar means to increase the productive powers of their own properties or farms. I may soon, perhaps, write you more fully on this important subject; but, at present, I have with difficulty found time even to write you these few lines.—*James Campbell, Dundee.*

Waste of Manure.—In these times of low prices, unusual exertions must be made, and an improved system of cultivation adopted. The soil undoubtedly, were it cultivated aright, would send into the market a third more of the staff of life than it does at present. To attain this desirable object, nothing should be wasted. The dust from the house, ashes of every description, soap suds, the wash not used for the pigs,—indeed, anything tangible either solid or fluid, should go to the general mass of fructifying materials; not, however, placed in a heap in order to allow the most nourishing parts to escape, but cast into a large tank formed out of the soil, if stiff and clayey; and if sandy or loose, the sides and bottom must be bricked. Nitrate of soda on Grass land answers remarkably well every other year, and brings up heavy crops. Grazing the land, or a dressing from the dung-hill on alternate years, keeps the field in good heart, provided it is judiciously drained; without which precaution the expenditure of rich dressings, in anticipation of remunerating crops, is labour in vain. Companies established in all large towns for the purpose of collecting the refuse, &c., and applying them to Agriculture, offer excellent speculations to an overflowing money market, promising a certain and large per centage. It must be acknowledged that a manure composed of a great variety of substances, is more beneficial on any kind of soil than one particular ingredient; this must continue to be the case until a simple mode of analysis can be discovered, by which the component parts of the land may be annually ascertained. The object of these remarks is not to depreciate the value of many excellent preparations lately introduced into this country, but to show that a superior manure exists within the reach of all farmers and gardeners, which is now permitted to waste its fragrance uncared for.—*Falcon, Cheltenham.*

Guano and Turnips.—On reading, at page 174 of the *Agricultural Gazette*, the statement made by John Henry Vivian, Esq., M.P., as chairman of the Swansea Farmers' Club, respecting the failure of his Turnip crop that had been manured with guano, it reminded me of a similar occurrence which happened to a friend of mine in this neighbourhood, and of which I was an eye-witness. Hearing so much about the wonderful effects of

guano as a manure, induced him to make trial of it for part of his Turnip crop; and not knowing anything of its nature, or of the mode of using it, he thought the best plan he could adopt was to sow the guano and Turnip-seed with the Turnip drill, in the same way as when bones are used. He accordingly did so; and after waiting for some time, he wondered why no Turnips made their appearance, as they were doing in other parts of the field. On examining the drills, he was surprised to find that some of the seed had chipped, and made an effort to grow, but had afterwards shrivelled up. Others, again, looked as if they had been kiln-dried, and lost their vegetative power. As a matter of course, the guano was blamed as the cause of the failure, and most heartily was it and every other new kind of manure abused. Nothing, in his opinion, would ever surpass good old farm-yard manure, and anybody might have his share of guano for what he cared about it. Happening to ride past at the time my friend had made this unfortunate discovery, I recommended him to have the part of the field harrowed afresh and sown again, by way of experiment—for I ought to observe, he had applied the guano at the rate of rather more than 3 cwt. per acre. He adopted my suggestion, and, singular enough, in the course of some days, the Turnips which had been sown broadcast made their appearance in rows from one end of the field to the other, marking as distinctly as possible the lines where the drill had deposited the guano in the first sowing. In due time, the intermediate spaces were horse-hoed, and the Turnip-rows thinned to a proper distance. Nothing could exceed their luxuriance. Although sown nearly three weeks later than the main crop, they soon overtook them, and became far superior in every respect—so much so, indeed, as to be the subject of general remark in the parish. Hence I think it may be safely laid down as an axiom in the use of guano, and which has been already mentioned in the *Gardeners' Chronicle*, Vol. iii. p. 383, *that it should never be applied in contact with seeds, as it kills the embryo in germination.—M. E. H.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A Weekly Council was held at the Society's House in Hanover-square, on Wednesday last, the 27th of March, present, T. R. Barker, Esq., in the Chair; Col. Henderson (Mayor of Southampton), R. Westbrook, Baker, Esq.; J. R. Barker, Esq.; J. Benett, Esq., M.P.; W. R. Browne, Esq.; F. Burke, Esq.; J. W. Bury, Esq.; F. C. Cherry, Esq.; L. Cooke, Esq.; C. Cure, Esq.; E. D. Davenport, Esq.; A. E. Fuller, Esq., M.P.; B. Gibbs, Esq.; T. Mainwaring, Esq., M.P.; R. A. Slaney, Esq.; Prof. Sewell, and J. Spencer Stanhope, Esq. The following gentlemen were elected members of the Society:—

Child, William, Vernham Manor, Andover, Hants.
Fletcher, Alexander, Millbrook, Southampton.
Coupland, J., Southampton.
Perry, John Watlington, Moor Hall, Harlow, Essex.
Perry, Richard, 18, Chester Terrace, Regent's Park.
Hussey, Edward, Scotney Castle, Lamberhurst, Kent.
Kerrison, Edward Clarence, Stanhope-st., Mayfair.
Holloway, Horatio, Marchwood, Southampton.
Spearing, John B., Chilton, Hungerford, Berks.
Kitson, Rev. Robert, Dean Vicarage, Ashburton, Devon.
Bent, Major John, Wexham Lodge, Slough, Bucks.
Milner, William, Nunappleton, Tadcaster, Yorkshire.
MacNiven, Charles, Perrysfield, Oxted, Surrey.
Newbery, Charles, Godstone, Surrey.
Beardmore, John, Uplands, Fareham, Hants.

The names of 15 candidates for election at the next meeting were then read.

Tussac Grass.—Sir William Jackson Hooker, K.H., Director of the Royal Botanic Gardens at Kew, in reply to an application which had been made to him on the part of members of the Society, who, in consequence of the publication in the Journal (vol. iv. part i. page 17) of an extract from Governor Moody's Despatches to Lord Stanley, having reference to the Dactylis cespitosa, or Tussac Grass, growing on Peat-bogs in the Falkland-Islands, were desirous of obtaining small portions of the seed for trial, favoured the Council with the following communication on the subject:—"I should be but too happy, were it in my power, to send you seeds or plants of the Tussac Grass. Some of the latter were living on their arrival in England, but they soon sickened and died. The seed, to a great extent, has been given away and sown in the Royal Gardens, in all kinds of situations, but not a single grain has germinated anywhere. Indeed, I have reason to believe that, in such a climate as that of the Falklands, and with a great disposition to increase by the roots, the Tussac seldom produces perfect seeds; not always, certainly, because while my son was with the Governor there, he raised seeds in the Government garden. I do not despair yet of introducing it. I have a Ward's Plant-case now in the Falklands, and have given instructions to have good tufts of the Grass with roots planted in this case, and *established* before the box is sent home. Should I be successful, you may rely upon it I shall not forget the Royal Agricultural Society." The Council ordered their best thanks to be returned to Sir William Hooker for this communication.

Bone Sawdust.—Messrs. G. W. Lees and Co., of 47, Fleet-street, transmitted to the Council a box of sawdust obtained from bone by means of the lathe, in the ordinary process of button-making. The soundness of the material necessarily employed for that purpose, and the favourable state of division into which it was reduced by the operation of turning, led them to infer that a greater uniformity would attend the application of bones as a manure under these conditions, and a greater produce result from their action, than when employed in their impure or imperfectly reduced state: and they accordingly had received from members of the Society residing in Hampshire and Hertfordshire comparative results of experiments which fully corroborated their opinion. Mr. Fowle, agent of Sir William Heathcote, Bart., M.P. of Hursley Park, near Winchester, had found the bone saw-dust applied to turnips far superior to any other manure he had made use of for that purpose; and Mr. Heard, of St. Margaret's, near Ware, states: "Two tons and a half of the bone saw-dust were applied upon 10 acres for turnips. The crop was excellent. The "rest" part of the field, 15 acres, was manured in the usual way with farm-yard manure, and the crop was an entire failure, after sowing even a third time. The fly did not attack the part done with the bone saw-dust, but totally destroyed the plant where the farm-yard manure was used."

Bones, Guano, and Ashes.—Mr. Slaney, of Walford Manor, near Shrewsbury, communicated to the Council the results obtained by Mr. T. C. Eyton, a member of the Society, residing at Donerville, in the county of Salop, in his experiments on artificial manures, especially on bones dissolved in sulphuric acid, embodied in a lecture delivered by that gentleman to the members of Wellington Farmers' Club, and at their request printed and published at a small nominal price by Simpkin, Marshall, & Co., London. Mr. Eyton having detailed various experiments made by other parties, proceeds to those instituted by himself, and which are of a very interesting character. "The manures and mixtures of manures I tried," says Mr. Eyton, "are calculated per acre. The Turnips, which were Skirving's Swedes, were mildewed, or probably the crops would have been larger. The largest crop is that raised upon guano and wood-ashes, at an expense of about two pounds four shillings, per acre, or at three half-pence for each bushel of Turnips; the cheapest, that raised upon bone-dust dissolved in sulphuric acid, at an expense of eight shillings and five-pence half-penny per acre. Both guano and muriate of ammonia were tried by themselves, and also mixed with gypsum, at the rate of 220 lbs. to the acre; where the gypsum was applied with muriate of ammonia, the crop was worse than where the muriate of ammonia was applied alone; where gypsum was applied with guano, the crop was only better by six cwts. in the acre than where none was applied, which may have been caused by the vicinity of a drain. We may therefore, I think, fairly conclude, that gypsum is no manure for Turnips, whatever it may be for Clover and other crops. I confess, I am much puzzled by this result, as from an analysis of the subsoil of the field, by the Messrs. Blunt, of Shrewsbury, it appears that it contains merely a trace of sulphate of lime, or gypsum; from which I should, until these experiments were tried, have supposed that gypsum would have had a powerful effect. Muriate of ammonia does not appear to answer well in the quantity used, and if larger quantities were applied, it would be too expensive for the farmer.

No. of Exp.	Description of Manure.	Cost per Acre.	Weight of Crop per Acre.	Measure per Acre.	Cost per Bushel.
		l. *s.* *d.*	Tons Cwt.	Bsh.	*d.*
I.	165 lbs. of muriate of ammonia; 220 lbs. of gypsum	1 10 11	7 1½	154	2¼
II.	330 lbs. of guano	1 13 0	15 1	308	1½
III.	165 lbs. of muriate of ammonia	1 6 6	8 16	192½	1¾
IV.	330 lbs. of guano; 220 lbs. of gypsum	1 17 5	15 14½	346½	1½
V.	330 lbs. of guano; 11 bushels of wood-ashes at 1*s.* per bushel	2 4 0	17 7½	423½	1¼
VI.	165 lbs. of muriate of ammonia; 11 bushels of wood-ashes	1 17 6	14 19½	385	1¼
VII.	1322 gallons of liquid manure (consisting of urine and soapsuds)	..	11 9¼	269	..
VIII.	66 lbs. of bones; 8¼ qts. or 33 lbs. of sulphuric acid; 550 gallons of water	0 8 5½	14 6	346½	0¼
IX.	484 lbs. of bone-dust	1 1 7½	14 19½	308	0¾

"In the above calculation, fractional parts are not included: the following is an analysis of the subsoil. I was told by a former tenant of the field, that it would not grow Turnips; it was, however, drained shortly before the Turnips were sown.

One hundred parts of the soil were found to contain:

Water	11 parts
Silica (or sand)	70 ,,
Alumina (or clay)	15 ,,
Red oxide of Iron	1½ ,,
Carbonate of Lime	1½ ,,
(Loss)	1 ,,
A trace of Sulphate of Lime, in weight not appreciable.	—
	100

"The proportion of silica is that yielded by the soil after the largest stones or pebbles had been removed from it. The seed was sown on the 17th May, 1843, and the Turnips pulled and weighed on the 22d of November. The plants all came up together; nor was there any perceptible difference in their appearance on the 27th of May; on the 14th of June, No. II. appeared to take the lead; I., VII., VIII. looking the worst, and being more backward than the others. On the 20th of June they were horse and hand-hoed; Nos. IX., X., VIII., IV., and V., were equal in appearance to No. II.; on the 21st July, No. V. looked best, and No. I. worst of all." Mr. Slaney then proceeded to call the attention of the Council to the comparative cost of the different manures tried by Mr. Eyton, and stated in the Table just read to them, from which it appeared that the bones and sulphuric acid cost only one farthing per bushel on the Turnips grown; whilst the other manures cost from three to ten times as much. The soil on which they were raised was a tolerably light loam, and, as Mr. Eyton stated, had been recently drained. The bones used were ground into powder, and were the fine siftings from collections of bones. This bone-powder being put into an earthenware vessel, a small quantity of water was first poured over it, and the sulphuric acid then added; when the whole mixture was stirred with a stick, until the bone-powder was entirely dissolved, and the solution being diluted with more water, was ready for use. It was applied to the land as liquid manure, either by means of a common watering pan, or the distributing trough of a liquid-manure cart, care being taken that the liquid should fall on the rows of Turnips just sown. This process, Mr. Slaney understood, was repeated after the plants came up; and in submitting this brief statement of Mr. Eyton's experiments to the Council, he trusted that the interesting results obtained might stimulate other members of the Society to extend the inquiry to other artificial manures, with a view to the determination of their economical application and practical value.—Mr. Davenport, of Capesthorne, near Congleton, Cheshire, fully corroborated the statement made by Mr. Slaney, in reference to the mode in which the mixture of sulphuric acid and bone-dust should be conducted; and as some danger to the inexperienced operator was to be apprehended, from a different mode of proceeding, it was desirable that great care should be taken, not only to effect the solution of the bones, but also to add the sulphuric acid in so cautious a manner as to prevent its accidental ejectment from the vessel, in consequence of the violence of chemical action. With regard to the abstract value of sulphuric acid and bones as a manure, he adduced the opinion of Mr. Burness, of Manchester, a pupil of Professor Liebig, and who had been delivering a lecture or two in Cheshire on Agricultural Chemistry, as unfavourable to its exclusive use; for, although it was no doubt a powerful and excellent restorer of land, it could not be considered as a permanent and efficient manure for rotation of crops, unless combined with other substances.—Mr. Davenport preferred bone manure in a dry concrete form to its being in the state of liquid solution; and had found a mixture of half a ton of bone-powder, and two hundred-weight of guano answer extremely well. The African guano just imported was offered at 3*l.* per ton less in price than the Peruvian guano, but he understood that it contained a correspondingly greater amount of water in its composition. Mr. Townshend Mainwaring, M.P., of Marchivial Hall, near Wrexham, Denbighshire, stated that with him the application of the sulphuric acid and bones had been attended with decided injury rather than advantage to his crops; a result, he had since learned, occasioned probably by the bones employed being left in fragments of too large a size, and consequently not in a state to be at once subject to the chemical action of the sulphuric acid as their solvent; his land having thus not only lost the advantage of the nutriment contained in the bones, but received, on the contrary, the injury of a strong, corrosive, and unneutralised acid.—Mr. John Raymond Barker, of Fairford-park, Gloucestershire, communicated the results of two experiments he tried last year on the effects of ashes, both singly and mixed with guano, on the growth of Swedish Turnips. The first experiment was made by applying a mixture of 40 bushels of coal-ashes, and 20 bushels of wood-ashes, per acre, to a bad piece of heavy land, sown with Skirving's Purple-top Swede, drilled in rows 18 inches apart. The Turnips, on being cleared of their tops and tails, were weighed, and found to give an average of 39 tons, 15 cwt. to the acre. The other experiment was made in a field of good light land, manured with 25 bushels of coal-ashes, and 1 cwt. of guano per acre, and sown with Skirving's Purple-top, in rows 27 inches apart. In this experiment the Turnips were much larger than in the former, and Mr. Barker expressed his regret that the result had not been weighed, as the crop was, without exception, the finest he had ever witnessed, the Turnips being of excellent quality, and of immense size.

Destruction of Insects.—Mr. Read, of Regent Circus, Piccadilly, had leave given him to submit to the inspection of the Council his garden syringes for throwing currents of aqueous vapour or narcotic fumes over the surfaces of trees and plants infested with noxious insects, without the slightest injury to their bloom or foliage. By an ingenious arrangement of the nozzles of the syringes, the currents could be directed to any given point without inconvenience to the operator; and water being introduced into the syringe in its liquid state, passed out through the nozzle as vapour or mist, settling on the plants as the gentle dew. Mr. Read had the thanks of the Council for the favour of this inspection.

Southampton Meeting.—Colonel Henderson, Mayor of Southampton, laid before the Council copies of the various engagements entered into by the Local Committee of the town and neighbourhood of Southampton, with the owners and occupiers of the various sites selected for the purposes of the meeting; along with a Surveyor's plan of the ground on which it is intended to erect the pavilion. These documents were received with thanks, and referred to the general Southampton Committee.

Prizes for Essays.—Mr. Burke gave notice that he should move, at the next monthly Council, "That Silver Medals should be granted to the authors of Essays not entitled to a first prize, but which are yet thought by the Judges to be worthy of commendation; all such Essays to remain the exclusive property of the Society, and to be made use of in such manner as the Society may think proper."

The Agricultural and Commercial Society of British Guiana transmitted a copy of their proposed laws and regulations; Mr. Sproule of Dublin, copies of his "Essay on the Growth and Management of Flax in Ireland;"

and Mr. C. M. Willich, a copy of the annual Supplement to his "Tithe Commutation Tables:"—for all which thanks were ordered. The Council then adjourned to Wednesday next, the 3rd of April.

AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

Mar. 21.—At the meeting of the Council, the Secretary laid on the table the report of the sub-committee, on reclaiming waste lands in Ireland, relative to the essay or report of Wm. Steuart Trench, Esq., upon the subject, for the Society's medal. The report, which was prepared by Acheson Lyle, Wm. Sherrard, and Wm. Jones Armstrong, Esqrs., entered fully into the subject, and stated that they considered the claimant fully entitled to the medal, for the spirited and enterprising way in which he had executed the work, and also deserving of considerable praise for the mode in which the subject has been treated in the report itself. They felt, however, that it was deficient in some respects, particularly as regards the different items of expenditure; and for this reason the report, together with the observations of the sub-committee, were ordered to be referred back to Mr. Trench, to make such observations by way of notes and commentaries as he should desire, in order to make the work the more valuable for publication in the Society's Transactions this year. A letter was read from Thomas Butler, Esq., one of the sub-committee for perusing the Essays on Manures, stating that he had entered into correspondence with Mr. Blacker and Mr. Coddington, who were associated with him for the purpose, and that they were inclined to pronounce a verdict of "no merit" upon the different productions which had been submitted to them for their decision. It appeared that the Society had only hitherto offered a silver medal for essays and literary productions of the kind, which had completely failed in producing anything valuable or worthy of publication; and that it was most desirable, if the funds of the Society would allow it, that some more substantial prizes in money should be given, for the purpose of procuring valuable information upon the subjects more directly connected with Ireland, and of giving them general publicity among the farming classes.

FARMERS' CLUB.

Cardiff.—At the monthly meeting of this Club, held on the 3d inst., Mr. David in the Chair, the subject for discussion, adjourned from last meeting, was On Road-making, and the Advantages of Turnpike Roads to the Agricultural Interests. The chairman said that few farmers were fully aware of the amount of hauling required on a farm of moderate size, especially if it were an arable one; this item of labour is greatly reduced by having a good hard road to go over. He himself had not believed it was so extensive until he had made the calculation he held in his hand, which he should be happy to submit to the meeting, and should be glad to have it corrected, if they thought necessary. In the first place, he would suppose that a farmer had to lime—

20 acres, at 7 tons per acre	140 tons.
Lime-coal required	60
20 acres of Turnips dunged at 20 tons per acre	400
60 acres of Corn, of all sorts, to be harvested and stacked, at 4 tons per acre	240
40 acres of Hay, ditto, at 1 ton per acre	40
Half the Turnips to be consumed in the farm-yard, or hauled off the field—10 acres, at 15 tons per acre	150
5 acres of Potatoes, at 6 tons per acre	30
Corn to market, crop of 60 acres, at 1800 bushels, at 56 lbs. per bushel, 45 tons—just say only	40
Haulage of stones off Clover, also for draining, materials for repairs, artificial manures, &c.	100
Total	1200

Few of them, perhaps, had imagined that the operations he had stated required so much labour in hauling, and a moderate size farmer would have all these operations to perform; therefore, he believed he had made out that road-making was an object of importance to the occupier of land in general, yet the bye-roads in this country were, in general, in the worst condition possible—often almost impassable—and this in a country abounding in the best materials, most of our roads passing over a lime-stone rock. He believed he might safely say that more money was wasted on the small parish roads in this county than on any other operation connected with the farm.—Mr. Watson said that drainage was a most important point to be attended to. He had recently witnessed the beneficial effects of drains under a road in a very striking manner. The road, which was a very public one, was always wet in the centre. He had recommended an underground drain, and since this had been done it had been always dry and firm.—Mr. Evan W. David bore testimony to the good effect of drains through the centre of roads on swampy land, having seen a piece of road at Deanston, in Stirlingshire, which had been treated in that way under the direction of Mr. Smith. This was done as an experiment, the portion adjoining having been dealt with quite similar in other respects. When he (Mr. D.) examined the road there was a very great difference in the two portions. The part drained was sound and good, while the other was in ruts and pools.—*Abridged from the Cardiff Advertiser.*

Reviews.

Thorough Drainage in Principle and Practice, as applied to a Dead Level. By John Clarke. Simpkin, Marshall and Co. pp. 46.

This is a very neatly got up pamphlet, describing the present condition of the alluvial and fens land in Lincolnshire, and the practical details of modes of drainage applicable to so flat a country. It is addressed to the landed proprietors and others connected with these districts, and will, we doubt not, be extensively read by them. It contains tables of the expenses connected with different kinds of drainage under various circumstances, and is also accompanied by a very accurate statement of the principles on which their efficiency depends. It is drawn up on a very complete plan, and seems well calculated to be an extensively useful little work on the subject.

Miscellaneous.

Trenching with the Spade.—An experiment, that was made in trenching last year, was attended with the following results. The field was about five acres; the soil a strong clay. The tenant had refused to plough it again, as he said it would not bear a corn crop. It was double-trenched in the manner mentioned. The price of the trenching was 10*d.* a rod of seven and a half yards, which amounted to 3*l.* 11*s.* 10*d.* the acre. A tolerable crop of Oats followed this management, perhaps from three to three and a half loads per acre. The grasses which have succeeded them are rich and luxuriant to a degree; and what the most striking circumstance is, that one butt, by some mistake, having been omitted being sown, the difference on this is most remarkable, there being scarcely the appearance of a good grass root upon it, and little else but thistles or the coarsest weeds.—*Rawstorne's Remarks on Lancashire Farming.*

Notices to Correspondents.

Rural Chemistry, By Edward Solly, Esq., F.R.S., Experimental Chemist to the Horticultural Society of London, Hon. Mem. of the Royal Agricultural Society, and Lecturer on Chemistry at the Royal Institution, has been reprinted from the *Gardeners' Chronicle*, with additions, and may be had of all Booksellers, price 4*s.* 6*d.*

Gas-water.—*Gowyn.*—Next week.——*H. H.*—The quantity you may apply depends on its quality, which is various. *Mr.* Paynter, of Cornwall, spread 400 gallons per acre undiluted, with benefit. Apply it now.

Guano.—*A Young Farmer.*—Apply two or three cwt. per acre, according as it appears to be required, and mix it well with a lot of earth before spreading.

Italian Ryegrass.—*Gowyn.*—Sow about 1½ bushel per acre.

Lime.—*A Nottinghamshire Subscriber.*—Apply the lime on the Wheat stubble in autumn. Thistles will ultimately die out if you cut them off whenever they appear.

Liquid Manure.—*Anglus.*—You had better put sulphuric acid, till effervescence ceases, into the tank, before throwing the water over the manure heap.

Mangold Wurtzel.—*Dr. H.*—Always use fresh, *i. e.* last year's seed. That of the year before will rarely sprout.

Nitrate of Soda.—*S. L. B.*—Apply to Mr. Fothergill, who reports for us the state of the manure market.

Old Mortar.—*Alpha.*—It will do very well to mix it with road scrapings and a small portion of salt.

Pigs.—*A. H.* is desirous of knowing where he can hear of a thorough-bred breed of Neapolitan Pigs.

Sheepskin.—*Economist.*—Soak the skin in tan-water in a tub for two months; and if you first dip it in lime-water for a short time, it will acquire a red colour. Your best plan is to send it to the tan-yard.

Tallow Refuse.—*An Improver.*—You had better break it small and moisten it in a heap. Decomposition will soon ensue, and you may then mix it with a quantity of farm-yard or other bulky manure. The compost will be valuable.

Whitfield.—*Querist.*—No Report for 1843 has been published. We will endeavour to obtain an account of the experiment you allude to.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, Monday, March 25.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s	3	to 3s	6	Best Downs & Half-breds	4s	0 to 4s 4
Best Short Horns	3	4		3	8	Best Long-wools	3	10		4	2
Second quality Beasts	3	0		3	4	Ewes and second quality	3	4		3	8
Calves	4	0		4	8	Pigs	3	4		4	0

Beasts, 2200; Sheep and Lambs, 25,240; Calves, 75; Pigs, 320.

The supply of Beasts continues good. The trade is heavy, and it is very difficult to maintain our highest quotations. The best Scots are, however, making 4s, but it must be a very good selling Short-horn to make 3s 8d.—the more general price for this description is 3s 6d. We have several more Sheep to-day, and a consequent reduction in price, the best Downs sell heavily at 4s 4d, and for the most selling Longwools 4s 2d is the very top. We observe more shorn Sheep to-day, but trade for them is heavy, at from 3s 8d to 3s 6d per 8lbs. Lamb is more in demand, at from 5s 8d to 6s 4d for small ones of good quality. Veal trade is very heavy, at lower prices. Pork also is lower.

Friday, March 29.

Since Monday, the trade at the dead markets has been so bad, that there are very few buyers here to-day. We have in to-day several that were left over from Monday, and a fair supply of fresh Beasts, but an exceedingly small demand; a great many cannot be sold at all; what sales are effected scarcely support Monday's prices. A prime little Scot is worth about 4s, but the very best Short-horns are more than 3s 6d. Sheep are tolerably plentiful, and the demand is so limited that a great many remain unsold; the very best Downs support Monday's price, but other qualities, in what few are sold, suffer a reduction of quite 2*d* per 8 lbs. There are several shorn Sheep; the trade for them is excessively bad. Lamb is the only trade in which there is any life, there being an increased demand, and rather shorter supply; small selling ones are making from 6s 4d to 6s 8d, large ones from 5s 4d to 6s per 8 lbs. Veal trade is exceedingly dull, the very best scarcely makes 4s 8d. Pork is rather lower.

Beasts, 784; Sheep and Lambs, 3780; Calves, 133; Pigs, 818.

41, West Smithfield.

Choice ditto - -	7 0 — —		

Patteson & Smith, Hop-Factors.

MARK LANE, Friday, March 29.—There are no fresh arrivals of English Wheat, and the parcels left over sell at rather lower prices than on Monday. Free Foreign is a slow sale, and scarcely maintains that day's rates. In Bonded there is nothing doing.—Malting Barley continues in demand.—Beans and Peas are unaltered in value.—There is very little doing in Oats.

COVENT GARDEN, March 29.—The weather during the week being fine, the market has, generally speaking, been well supplied; but trade is not brisk. Pine-apples are sufficient for the demand, and they are offered at nearly the same prices as mentioned last week. Hothouse Grapes continue to be supplied, but only in small quantities; they are selling at 15*s.* per lb. Good Apples are scarce, and have advanced a little in price since our last report; the best dessert varieties are offered at 28*s.* per bushel. Little alteration has taken place in the price of Pears. Oranges are abundant, and Lemons are sufficient for the demand; Chesnuts bring the same prices as last week. Vegetables begin to improve; Broccoli is good, and continues to get cheaper. Savoys are becoming very scarce, as are also Brussels Sprouts; the former has slightly advanced in price. Greens are still sufficient for the demand. Carrots and Turnips, of excellent quality, are abundant; they are not altered in price. Seakale and Asparagus are well supplied, and are good in quality; the latter is a little reduced in price. French Beans are sufficient for the demand. Rhubarb is good in quality, and very plentiful. A good many of the Syon-house Cucumber have been brought to the market lately, but they do not sell so well as either the Black or White Spine, which meet with a ready demand. Strawberries are good, and are becoming more plentiful. Frame Potatoes are offered at 3*s.* per lb. Cut flowers chiefly consist of Erica Willmoreana, E. Westcotii, Euphorbia Jacquiniflora, Gardenias, Azaleas, Camellias, Pelargoniums, Cinerarias, Fuchsias, Primulas, Lily of the Valley, Mignonette, and Roses.

FRUITS.

Pine Apple, per lb., 8s to 10s	Almonds, per peck, 6s to 7s
Grapes, Portugal, per lb. 1s to 3s 6d	Sweet Almonds, per lb., 2s 6d to 3s
Apples, doz., p. bush. 8s to 28s	Nuts, Spanish, per bushel, 18s
— — Kitchen, p bus. 5s to 10s	— Brazil, 16s
Pears, per half-sieve, 4s to 12s	— Hazel, 3s to 4s
Oranges, per dozen, 9d to 2s	— Barcelona, 20s to 24s
— per 100, 5s to 14s	— Cob, 12s
Lemons, per doz. 1s to 3s	Chesnuts, per peck, 3s to 6s
— per 100, 6s to 14s	Strawberries, 1s 6d to 2s per oz.

VEGETABLES.

Rhubarb, per bundle, 1s to 2s 6d	Spinach, per sieve, 1s 6d to 2s
Broccoli, per bundle, 1s to 1s 6d	Leeks, per doz. bun., 2d to 1s
White Brocooli per doz. from 2s to 6s	Garlic, per lb. 4d to 6d
Brussels' Sprouts, p.h.-sv., 1s 6d to 2s 6d	Onions, 2d to 4d p. bch.,
Red Cabbages per doz. 2s to 3s	— Large, per bushel, 1s 6d to 2s
Sorrel, 1s to 1s 6d p. hf.-sv.	— Spanish, per doz., 1s to 4s
Asparagus, per 100, 3s to 12s	— pickling, p hf.-sv., 2s to 4s
Seakale, per punnet, 2d to 2s 6d	Shallots, per lb., 4d to 6d
French Beans, 1s 6d to 3s per 100	Lettuce, Cabb., p. score, 6d to 1s
Autumn Potatoes, 3d to 6d per lb.	Celery, per bun., 6d to 2s
Savoys, per doz. 1s 6d to 3s	Mushrooms, per pottle, 1s 6d to 2s
Greens, per doz. 3s to 6s	Walnuts, per bushel, shelled, 16s to 20s
Potatoes, per ton, 60s to 90s	Small Salads, per punnet, 2d to 3d
— per cwt., 2s to 3s	Watercress, per doz. sm. bun. 6d to 9d

Turnip-tops, per bushel, 6d to 1s	Green Mint, 4d to 6d per bunch
Red Beet, per doz., 6d to 1s	Marjoram, p. doz. bun. 1s 6d to 2s
Horse Radish, per bundle, 1s to 6s	Chervil, per punnet, 2d to 3d
Radishes, spring, 10d to 1s 6d p. punn.	Salsafy, per bundle, 1s to 1s 6d
Carrots, p. doz. bun., 3s 6d to 5s	Scorzonera, per bundle, 1s to 1s 6d
Cucumbers, 6d to 4s each	

POTATOES.—Southwark Waterside, March 25.

The heavy gales of wind the early part of the week prevented the arrivals anticipated, and the cold north-east winds checked vegetation, which caused an extra demand for Potatoes, and a further advance on some samples was maintained. The Farmers having been fully employed with their field operations, they have not had time to ship, and our market still feels the hindrance to the shipping caused by the late snow-storm in the north, and since the roads have been opened, many cargoes have been shipped to Yorkshire for plants. Several cargoes arrived from the northern districts the end of the week, yet the supply is moderate, especially for this season of the year. The weather became more genial the last two days, and the dealers only purchasing for present use, sales were languid at the annexed quotations:—

York Reds - - -	80s	to 90s	Kent and Essex Whites -	60s	70s
Perth - - - - -	80	85	— — Kidneys -	80	85
Early Devons - - -	—	—	Wisbeach Kidneys - -	80	85
Late Devons - - -	80	—	— Blues - - -	—	75
Cornwall - - - -	85	—	— Whites - - -	65	70
Jersey and Guernsey Blues	90	—	Prince Regents and Shaws	65	80

WOOL.—British, Friday, March 29.

Our Wool Market continues quiet, and there appears a disposition to quit stock whenever it may be done at late quotations; but we do not think any reduction in price since our last can be quoted.

	per lb.			per lb.	
Long-wooled Wethers	1*s* 1*d*	to 1*s* 2*d*	Southdown Hoggits	1 1	to 1s 2d

Expenses of shipping about 3s to 7s per ton, according to quantity.

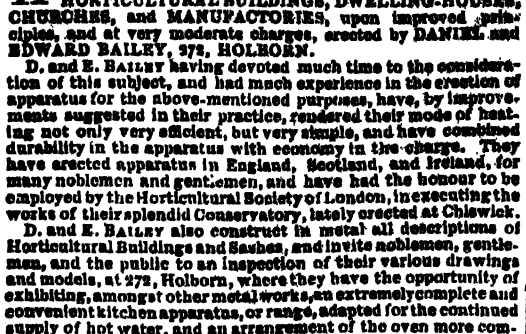
Mark Portsmouth.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.



D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

RENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance, can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of Iron will be found cheaper than of any other material. MR. RENDLE, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

BURBIDGE AND HEALY beg respectfully to inform the Horticultural world that they are quite ready to supply their new BOILER, of every size. They have now fixed a sufficient number to warrant them in stating that what they put forth as the qualities of their Boiler and Furnace arrangement may be perfectly relied upon: they have put up one at the Horticultural Gardens, where B. and H. believe it is considered to answer as represented; they have also fixed it in connection with a new description of Iron Tank, which combines the qualities of the round pipe and the open tank, which may be pronounced the perfection of a Heating Apparatus for Horticultural purposes, particularly for Graperies, Epiphyte-houses, Melon-pits, &c., &c. The arrangement is such that any gentleman or gardener may have the whole constructed so as to be put together with the greatest facility by the gardener, first sending a correct plan to 130, Fleet-street. A Prospectus may be had detailing the prices, &c.

COTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c. &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL-ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices, in consequence of the present depressed state of the Iron Trade.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public, or Private Buildings, &c., with COTTAM'S PATENT, or ROGERS' BOILERS. After 15 years' experience, and having fixed upwards of 1500 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale. For the convenience of those who wish to fix their own Apparatus, they have affixed the following low prices:—

Cottam's Patent Boiler, 18 inch . . .	£3 15s. 0d.
Rogers' Boiler, small size	1 17 0

Larger in proportion.

Hot-water Pipe, at 2, 3, and 4 inches, at reduced prices.

The TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

GARDEN ROLLERS 18 inches long, 34s.; 20, 44s.; 22, 50s.; 24 inches, 60s.; 26, 75s.; 28, 84s.; 30, 105s. each.

CAST-IRON RICKSTANDS, 2 feet six inches high, 5s. 9d. each. Garden Engines, Mowing Machines, Garden Chairs, Superior Garden Tools of all kinds, Garden Vases and Pedestals in great variety, and every description of Horticultural Articles, Agricultural Implements, and Furnishing Ironmongery; Dr. Arnott's Stoves, Anglo-Belgian Cooking Stoves; Broiling Stoves. The above low prices being on account of the depression in the Iron Trade, are subject to future alterations.

STRONG IRON HURDLES, 3 ft. high out of the ground, 6 ft. long, with five horizontal bars, weighing about 36 lbs., 3s. 6d. each. Light Cattle Hurdles, 3 ft. 6 in. high, weighing 42 lbs., 4 0 ,,
Strong do. do. do. 45 lbs., 4 4 ,,
Ox Hurdles, 4 feet high, do. 60 lbs., 5 6 ,,

BEST WIRE, for STRAINED WIRE FENCING, at 6s. 6d. per bundle of 130 yards each. Uprights for ditto, 7d. each. The improved continued, and every kind of Fencing, Fancy Wirework.

HAND-GLASS FRAMES for Cucumbers, &c., 18 inches square, 3s. 6d.; 20 inches, 4s. 6d.; 22 inches, 5s. 6d. each.

CAST-IRON FLOWER-STAKES, 4 ft. long out of the ground, 7s.; 4 ft. 6, 9s.; 5 ft., 11s.; 6 ft., 18s.; 7 ft., 20s. per dozen.

Show-Rooms at the Manufactory, No. 2, WINSLEY-STREET, where every information may be obtained.

E. WEEKS, Sen., Hortulan-place, King's-road, Chelsea, the original Builder of Hothouses, Conservatories, &c. &c., Inventor and Patentee for Heating by Hot Water, begs to inform the Nobility, Gentry, and Public that he has great improvements for inspection, surpassing anything yet seen. Houses of all descriptions ready for fixing.

GUANO ON SALE BY THE IMPORTERS,
JOHN BOYD & Co.,
Wellington Chambers, London-bridge, Borough.

GUANO, PERUVIAN, &c.—The above Manures, also Potter's Guano, Nitrates of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.

Lists of Prices, [illegible] mode of use, on application to MARK FOSTER [illegible] Thames-street, and 5, Railway Place, Mark-lane, London.

GUANO (GENUINE PERUVIAN & BOLIVIAN)
ON SALE, BY THE ONLY LEGAL IMPORTERS,
ANTONY GIBBS AND SONS, LONDON;
WM. J. MYERS AND CO., LIVERPOOL;
And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, March 29, 1844.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing a more rapid vegetation in Plants than any substance known. It may be had at Mr. LAWES' Factory, Deptford Creek, price 7s. per cwt. Phosphate of Potash, 18s. per cwt.
,, Soda. 12s. ,,
,, Magnesia 9s. ,,
,, Ammonia 1s. per lb.

THE URATE of the LONDON MANURE COMPANY, 5l. per Ton. It is with the greatest satisfaction, after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By promoting a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops. The Urate may be sown broadcast, or which is preferable, by the drill, at the rate of one ton to three acres, and it is desirable it should not be placed more than two inches below the surface. As a top-dressing for Wheat the Urate has been used with great advantage. Gardeners and Floriats will find it very useful for Dahlias and other roots. Full particulars and Testimonials will be forwarded on application. Genuine Peruvian Guano; Phosphate and Sulphate of Ammonia; Gypsum and every other artificial Manure.

EDWARD PURSER, Secretary, 40, New Bridge Street.

GLASS SUPERSEDED for HORTICULTURAL PURPOSES by WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, rendering Muslin, Calico, or Linen, for the Frames of Greenhouses, Pine, Melon, or Cucumber Stoves, &c., impervious to rain or moisture, admitting light equal to Glass, much warmer, and the plants never burn under it.

Noblemen, Gentlemen, and Gardeners will, by using this composition, have the only effectual protection for their Fruit-trees during the blooming season; it is a certain defence from frost, sleet, wind, and blight; its transparency admits the general beams of the sun, with abundance of light, which causes the bloom to expand with increased luxuriance, the fruit to set and swell more freely, much earlier, and a crop of fruit to any extent may be warranted. The covering not to be moved by day (except to thin the Fruit, which will be necessary), till the month of June. It is recommended that the Calico be prepared early, so as to be thoroughly dry before using.

Sold in Bottles, with directions for use, pints, 2s. 6d., quarts, 4s. 6d. each. One pint is sufficient to coat four Frames twice over, each Frame to be 5ft. by 3 ft. 3 in., or thereabouts. Prepared by GEORGE WHITNEY, Chemist, Shrewsbury. Seedsmen, Florists, and Merchants supplied by Mr. W. BAILEY, Chemist, North-street, Wolverhampton. Appointed Agents:—Messrs. BUTLER and MUCKLEY, Covent Garden, where a sample of prepared calico may be seen; Mr. WATKINSON, Market-place, Manchester; PAGE and SON, Southampton; T. and C. WHALLEY, Nurserymen, Liverpool.

Agents wanted for London and the country.

ASPHALTUM in its pure state, with all the material and instruction how to prepare, or if required, the labour performed at a moderate charge.

TOBACCO ASHES.—A few Tons of Tobacco Ashes to be Sold at 3l. per ton, convenient for land or water carriage.—Apply to J. A. HUBBARD and SON, 20, Harp-lane, Tower street. All Letters prepaid.

SUPERIOR SUBSTITUTE FOR TARPAULIN, &c.

C. MACINTOSH & Co., having made a considerable reduction in the price of the Patent India Rubber Covers for Carts, Waggons, Ricks, &c., beg to call the attention of Users of Tarpaulin and Oiled Sheets to the superiority of their manufacture as an effectual protection against wet, not liable to crack on being folded, and more economical than any other Waterproof Cover.—22, York-street, Manchester; and 46, Cheapside, London.

SLATE WORKS, ISLEWORTH, MIDDLESEX.

THE following Articles, manufactured in Slate for Horticultural purposes, may be seen in use at Worton Cottage, upon application to the gardener (Sundays excepted).

Tank Covers	Bottoms for Frames
Cisterns	Boxes for Balconies and Verandahs
Shelves	
Garden Edging	Orange Tubs, Flower Boxes, &c.

EDWARD BECK will be happy to answer any inquiries, either personally or by post.

TO AGRICULTURISTS.

THE Dry Material for making CAMPBELL'S CORN-PRODUCING LIQUIDS, or FERTILISING STERPS, which have arrested the attention of Agriculturists in all parts of the United Kingdom, is now to be had in Boxes containing quantities for 5 Gallons and upwards, at the following prices:— For WHEAT, Material per Gallon . . . . 2s. 6d.
,, OATS and GRASSES, ... 1 6
,, BARLEY, ... 2 0
,, BEANS and PEASE, ... 2 0
,, TURNIPS and RAPE SEED 2 6

Agents in London:—Mr. EDWARD PURSER, 40, New Bridge-st.; Messrs. GEO. GIBBS and Co., 26, Down-st., Piccadilly; and Messrs. THOMAS GIBBS and Co., Corner of Half-moon-street, Piccadilly.

LEVEL.—This Instrument, the invention of a Gentleman extensively engaged in Draining, is confidently recommended for its simplicity and cheapness; it requires only one person to use it, and gives the rise and fall in land as well as the level, and is also adapted for giving a uniform fall to drains. Each Level is packed in a case 18 inches by 8. Price, 2l. Direct to W. B. WEBSTER, Hounsdown, near Southampton.

DR. HALLETT'S LIQUID FERTILISER.—The beauty of Flowers, with their power of perfecting their Seeds, and the flavour and size of Fruits and Vegetables must ever depend upon the food supplied to the plants producing them; and these a very extensive series of trials on various soils has shown, may be secured by the use of DR. HALLETT'S CONCENTRATED LIQUID FERTILISER, which contains all the essential ingredients of the best foreign Guano, with others equally so, but not to be found in the Atlantic Ocean. Sold by Messrs. WARNERS, 28, Cornhill; Messrs. WINSTANLEY, 7, Poultry; and every other respectable Chemist and Seedsman; with directions, in stone quarts, at 1s. 6d. each. The liquid requires 64 parts of water to reduce it for use, for watering soils and growing bulbs in.

MOST IMPORTANT TO FARMERS AND GRAZIERS.

GIBBONS' DISINFECTING OINTMENT, a most effectual and perfect cure for Epidemic and Foot-rot in Sheep; also for Epidemic and Foul in Cows' Feet, and for the Grease and Thrush in Horses; prepared only by HENRY GIBBONS, Agricultural Chemist, Wolverhampton.

This Ointment effectually destroys the American grub on Fruit-trees. Sold by all respectable Druggists in Town and Country, in packets at 2s. 6d. each. Mr. William Bailey, Manufacturing Chemist, North Street, Wolverhampton, is appointed Sole Wholesale and Shipping Agent.

AGRICULTURAL IMPROVEMENT.

SPRING WHEAT.—HUMPHREYS'S FARMERS' COMPOUND, manufactured on a *new principle*, so as to present a cheap manure of greater power, and more extensive usefulness, than the guano; and without its caustic rankness, and liability to be washed out of the soil. From its wholesome character, it is unrivalled for garden culture; and as a Top-Dressing for all Spring Crops. Per acre, for WHEAT, BARLEY, &c., with a bad soil, *Five cwt.*; with better land, *Three or Two*. GRASS on the average, *Two cwt.* TURNIPS, THREE or TWO. Price 12s. per cwt. Agents, DAVY, MACKMURDO, & Co., Manufacturing Chemists, 100, Upper Thames-street, London. Factory, Great George-street, Bermondsey.

CHOICE FLOWERS and PLANTS in POTS.

HUMPHREYS'S COMPOUND, applicable to all Greenhouse Plants, to Cucumbers, &c., and to promote the germination of Seeds. Sold in bottles at 1s. 9d. each, by Messrs. FLANAGAN & SON, Mansion-house-street; HURST & MCMULLEN, Leadenhall street; W. CLARK, Bishopsgate-within; SMITH, Islington Nursery; GRIMLEY and Co., Covent Garden; BATT and RUTLEY, 412, Strand; WILLIAM and JOHN NORLY, Fleet-street; SMITH, Covent Garden; CHARLWOOD, Tavistock-row; W. J. NUTTING, 46, Cheapside; G. LAWRENCE, 12, Piccadilly; JOHN KERNAN, Great Russell-street, Covent Garden; LOCKHART, 156, Cheapside; SHUTTLEWORTH, Pantheon; MINIER, ADAMS, and NASH, 63, Strand; THATCHER and SON, Islington; J. FRYER, Clarendon-terrace, Camberwell; THOMAS ANSELL, Camden Town; THOMAS WATKINSON, Market-place, Manchester; T. S. KING, Rochester; W. K. RENDLE, Plymouth; DICKSON and Co., Edinburgh; PONTEY, Leeds; FISHER, HOLMES, and Co., Sheffield; P. LAWSON and SON, Edinburgh; J. THORNE, Shepton Mallet; and other leading SEEDSMEN in town and country. Wholesale Agents, DAVY, MACKMURDO, and Co., 100, Upper-Thames street, London.

100 CUCUMBER AND MELON-BOXES AND LIGHTS for Sale. One, Two, and Three-Light Boxes and Lights of all sizes ready for immediate use—best materials: packed and sent to all parts of the Kingdom by JAMES WATTS, Sash Manufacturer, and Hothouse Builder, Claremont-place, Old Kent-road. Garden Lights glazed and painted complete from 1s. per foot.

THE LATE MR. LOUDON.—The following Subscribers to the Works of the late Mr. LOUDON have been obtained since making up the list which appeared in the *Gardeners' Chronicle* of Saturday, March 16. A part of the following list should have appeared in the *Gardeners' Chronicle* of Saturday last, but it was unavoidably postponed for want of room.

THE LIBRARY OF TRAVEL.

On Saturday, the 30th of March, to be continued Weekly, price 4d., the First Number of

THE LIBRARY OF TRAVEL: being a Popular Description of Foreign Countries, with Notices of Scenery, National Characteristics, Incidents of Wayfaring and Sojourn, Personal and Historical Sketches, Anecdotes, &c.—Abundantly illustrated with Wood Engravings.—Edited by WALTER K. KELLY.

Each Weekly Number will contain Twenty full pages of letter-press, demy octavo, embracing such woodcuts as may be required to illustrate the Text. At the end of every month the Numbers will be collected into a Part, which will be issued with the Magazines; and the Parts treating of each country, or group of countries, as may be found most convenient, will be bound into volumes with separate title-pages.—SYRIA AND THE HOLY LAND WILL FORM THE FIRST VOLUME.

London: CHAPMAN and HALL, 186, Strand. Orders received by all Booksellers.

MR. YARRELL'S HISTORY of BRITISH FISHES. This Second Edition contains 37 new species not included in the First Edition, the whole number being now 363; 27 Fishes have been newly engraved, and 34 new Vignettes have been added. The Work now contains nearly 500 woodcuts. Two vols. 8vo, price 3l.

JOHN VAN VOORST, 1, Paternoster-row.

Now ready, with woodcuts, post 8vo, 12s.,

SCENES and TALES of COUNTRY LIFE, with Recollections of Natural History. By EDWARD JESSE, Esq., Surveyor of Her Majesty's Parks and Palaces.

JOHN MURRAY, Albemarle-street.

MAXWELL'S REBELLION in IRELAND, in 1798. Part IV., for April, price 1s., with Two beautiful Designs on Steel, by GEORGE CRUIKSHANK.

"There will be found in it some most interesting matter relating to persons and things, which cannot fail to attract attention."—*Morning Advertiser*, Jan. 5, 1844.

"This Part is filled with records of the most stirring interest, connected with the melancholy period to which it refers. The dreadful scenes which marked the progress of the rebellion are illustrated by George Cruikshank; and Mr. Maxwell, we understand, has collected his detail of the rise, progress, and conclusion of those disastrous times from the most authentic sources. They are indeed of the most romantic and horrifying description."—*Bell's Life in London*, Jan. 6, 1844.

Now ready, 2 vols. 8vo, cloth boards, 1l. 4s., Portrait.

WANDERINGS in the HIGHLANDS and ISLANDS, with Sketches taken on the Scottish Borders; being a Sequel to "Wild Sports of the West." By W. H. MAXWELL, Esq.

"The rapid, off-hand, dashing style of the author of 'Wild Sports' has the effect of rendering all his books agreeable..... Like Washington Irving, our old campaigner has a stout gentleman; and, verily, an admirable fellow he is, with a story enough to make the fortunes of half-a-dozen books, and clear out the wrinkles from the face of Old Care himself. We content ourselves by wishing our readers may laugh through Mr. Maxwell's pages as merrily as we did."—*Pictorial Times*, Jan. 20.

MAXWELL'S LIFE of the DUKE of WELLINGTON, K.G., in 3 vols. demy 8vo, bds., splendidly illustrated with Portraits, Battle Scenes, Plans of Battles, and Maps. Price 3l. 7s., or with proof plates, royal 8vo, price 5l., bound.

In 2 vols. 12mo, bound, 1000 pages, price 1l. 1s., illustrated by 24 Steel Engravings from the most authentic Portraits of the British Admirals, and numerous Diagrams of Naval Actions,

THE BATTLES of the BRITISH NAVY (from A.D. 1000 to 1840. By JOSEPH ALLEN, Esq., of Greenwich Hospital). "The best and most complete repository of the triumphs of the British Navy that has issued from the press."—*United Service Gazette.*

BAILY'S SERIES of WINNERS.—The above series comprises Portraits of the Winners of the Derby, Oaks, and St. Leger for 1843—to be continued—besides Portraits of Beeswing, Charles the Twelfth, and Confidence, the celebrated American Trotter, price 1l. 1s. each. Also in course of publication, a splendid Portrait of Alice Hawthorn.

BAILY'S SPORTING ALMANACK for 1844, price 2s. 6d., embellished by 12 highly-finished Illustrations.

DE LA VOYE'S NEW ENGLISH-FRENCH, FRENCH-ENGLISH LEXICON, 1100 pages, 10s. 6d. boards.

DE LA VOYE'S NOVEAU MELANGE. 12mo, boards, 4s. 6d.

DE LA VOYE'S NOUVELLES RECREATIONS FRANCOISES. 12mo, boards, 4s. 6d.

*** As no Advertisement could give a just idea of the variety and extent of the information contained in the above volumes, by M. DE LA VOYE, specimens will be sent, post paid, on applications to the Publishers, A. H. BAILY & Co., Cornhill, London.

NOW READY, price 1s.

PERUVIAN and BOLIVIAN GUANO, with Full PRACTICAL Instructions for its Use, and Testimonials of its Properties and Results.—JAS. RIDGWAY, Piccadilly, and every Country Bookseller. Also,

1. The Fourth Edition, enlarged, of Morton on Soils, price 10s.
2. Agricultural Chemistry for the Practical Farmer, by C. Squarey, 5s.
3. A New Edition of "Sinclair on Grasses." Coloured plates, price 30s.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.—SOUTHAMPTON MEETING.—Prize-Sheets and Regulations for the Exhibition of Stock, Implements, &c., together with the blank PRINTED FORMS OF CERTIFICATE required to be filled up by Exhibitors, and copies of the printed Programme of the Meeting, may be had on application, either personally or by letter, addressed to the Secretary, No. 12, Hanover-square, London.

Exhibitors are particularly requested to observe, that all Certificates for Implements, &c., must be sent, complete, so as to reach the Secretary on or before the FIRST OF MAY; and all Certificates for Stock on or before the First of June.

By order of the Council, JAMES HUDSON, Secretary.

London, March, 1844

CHOICE PANSIES.

J. HENCHMAN begs to inform cultivators of the PANSY that he is now sending out healthy plants of six good seedling varieties, for 21*s.* the set. Also a few choice kinds at 15*s.* and 18*s.* per dozen.—Edmonton, March 1844.

WOODLANDS NURSERY, MARESFIELD, near Uckfield, Sussex

WILLIAM WOOD AND SON have much pleasure in acquainting their numerous Patrons and Friends that they have been appointed Agents for the sale of that most invaluable article—WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, samples of which may be seen, and the composition in use, at WOOD AND SON'S Nursery. Sold in bottles, with ample directions for use, pints 2*s.* 6*d.*, quarts 4*s.* 6*d.* each. Discount to the Trade.

SEEDLING FUCHSIA, CACTUS, and PANSY, HOLLYHOCK SEED, &c.—LYNCOMBE VALE NURSERY, BATH.

J. KITLEY begs to inform the Nobility, Gentry, and the Public that he has purchased of Mr. POND his unequalled SEEDLING FUCHSIA (PONDII), allowed by all who have seen it to be one of the largest and handsomest Fuchsias of the day; tube and sepals bright crimson, with darker corolla, and extremely free bloomer; fine compact habit; cannot fail to give satisfaction. 5*s.* per plant.

J. K. has a few more plants of fine SEEDLING CACTUS (SPECIOSA SUPERBA), 10*s.* 6*d.* per plant. Also, good healthy plants of his SEEDLING PANSY (LYNCOMBE VALE RIVAL). This Flower, both for shape and decision of colour, is decidedly the best light PANSY out. 3*s.* 6*d.* per plant.

J. K. can recommend his HOLLYHOCK SEED, with the greatest confidence, having taken great care to select from his best full and very double Flowers of 1843 20 distinct varieties, named to colour, which he will forward to any purchaser post-free, on the receipt of a Post-office order for 5*s.* The whole of the above are now ready to send out.—Bath, April 5, 1844.

WILLIAM MILLER begs to direct attention to his Advertisements of PETUNIA "PUNCTATA," New VERBENAS, &c., in the past Numbers of the *Chronicle*.—Providence Nursery, Ramsgate, April 4, 1844.

PELARGONIUMS, AURICULAS, CARNATIONS, AND LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by APPOINTMENT FLORIST TO HER MAJESTY, begs to inform the Nobility, Gentry, and Amateurs, that in consequence of the success he has had in the cultivation of the above Flowers at his new Garden (where he requests an inspection of the quality of his plants), he can offer them at very moderate prices. His Catalogue of PELARGONIUMS, AURICULAS, and NEW PLANTS, is now ready, and will be forwarded by post on application. The Trade supplied.

BUSHELL'S Light Seedling DAHLIA, "EMMA."—Plants in May, 10*s.* 6*d.* Colour white, tipped with deep cherry; the petals, form, and centre good; the largest, most constant, and free in flowering, of any Dahlia yet propagated, and has obtained several prizes. "PET RIVAL," plants in May, 5*s.* Colour, purple maroon; fine cupped petal, and free bloomer; exhibited in several winning stands last season. "KENNINGTON ROSE," plants in May, 5*s.*; most constant rose grown. To be had of Messrs. ANSELL, Camden-town; S. GIRLING, Stowmarket; F. and A. SMITH, Hackney; and J. BUSHELL, 13, Hall-place, Kennington-lane.

CARNATIONS AND PICOTEES.

JOHN SLATER, FLORIST, Cheetham Hill, near Manchester, has on sale upwards of 1000 pairs of healthy plants of Carnations and Picotees, which he will sell at low prices. 20 pairs of Carnations and Picotees, one pair of each variety for 20*s.*, package included, provided the selection is left to J. S.

FASTOLFF RASPBERRY.

J. T. WILLMER begs to announce to his Friends and the Public generally that he is able to supply a few hundreds of the above-named Raspberry, in strong Canes, at 40*s.* per 100, warranted to be the genuine kind, packing included, with carriage paid to London; or in less quantity, price in proportion. Fine showing sorts of CARNATIONS and PICOTEES, in 12 kinds, one pair of each, 24*s.* AURICULA.—Strong Plants of showing sorts, 12 plants, in 12 sorts, including basket and packing, the selection left to J. T. W., who possesses a large healthy stock.—Sunbury Nursery, Middlesex, April 5, 1844.

A CATALOGUE of CHOICE DAHLIAS, sold by W. R. WHALE, FLORIST, &c. &c., Elcot, near Hungerford, Berks.

Whale's Preceptor, a seedling of 1842; bright crimson scarlet; good substance and outline; beautifully cupped petals; splendid show flower; fine habit; height, 4 ft.	10*s.* 6*d.*
Second—Crimson Perfection, of great substance, being 20 petals deep; high rising centre; fit for a back row flower in any stand; good habit; height, 4 ft.	10 6
Third—Mary; white ground, margined with rose-pink; a fancy border variety; constant and abundant bloomer; height, 3 ft.	5 0
Spary's Lady Antrobus; white ground, margined with scarlet lake; beautifully cupped petals; good substance and outline; took numerous prizes; decidedly the best light show flower of the season; height, 3 ft.	10 6
Second—Aurantia; on an orange buff; decidedly the best flower of its class; took several prizes; height, 4 ft.	10 6
Madeline (Daniel's); a beautiful lilac; good substance; fit for a back row flower; constant; height, 4 ft.	10 6
Prince of Waterloo (Drummond's); a shaded red; beautifully cupped petals; fine centre; took the first prize at Chippenham; placed before Keynes's Standard of Perfection, Lady Antrobus, and Brown's Lady St. Maur; first prize at Bath, &c.; height, 4 ft.	10 6
Sir H. Pottinger (Drummond's); dark plum-colour; cupped petals; good centre; a most desirable show flower; height, 4 ft.	10 6
Sir J. B. Richardson, Union; one of the best flowers of the season; height, 4 ft.	10 6
An improvement on the Duchess of Richmond.	
Opher Yellow (Edwards's); fine show flower; height, 4 ft.	10 6
Bermondsey Bee (Proctor's); crimson purple; fine show flower	10 6
Nonpareil (Proctor's); ruby scarlet; first-rate	10 6
Talmer (Girling's); purplish rose; good show flower	7 6
Royal Sovereign (Stanford's); bright yellow. This flower is little known, and scarce; was shown in Hampshire, Sussex, &c., last season in grand style; height, 4 ft.	5 0
Park Mount Rival; a superb yellow	10 6
Vanquisher (Wood's); shaded maroon; first-rate	10 6
Lady Stanford (Groves's); yellow; fine	7 6
Cheltenham Queen (Hodges's); white; first-rate	7 6

A Good Assortment of Fancy Varieties, at 12s. per dozen.

Oakley's Sun, Rise, Nihile, &c. &c. &c.

MAY'S "QUEEN OF MAY" CINERARIA.—The above new and beautiful Cineraria is now ready to be sent out by post, or otherwise, at 5*s.* 6*d.* each, including case, prepaid. It is confidently recommended as being one of the most splendid novelties that has been offered in Cinerarias; the colour being a beautiful light sky-blue; the flowers large and of good form; the plants compact, shrubby, and dwarf in growth.

W. M. begs to state that his descriptive List of new, superb Calceolarias may be had on application to WILLIAM MAY, Hope Nursery, Bedale, Yorkshire.

W. M. also begs to intimate that he cannot supply any more Eucharidium grandiflorum.

MESSRS. MARNOCK and MANLEY beg to inform their Friends and the Public, that their DESCRIPTIVE CATALOGUE OF FUCHSIAS, VERBENAS, CINERARIAS, DAHLIAS, &c., with a Treatise on the best and most successful Modes of Cultivation, is now ready, and may be had on application.

N.B.—Their beautiful Fuchsia, MARNOCK'S PRINCESS SOPHIA, is now ready to be sent out; the stock is not large, therefore early orders will prevent disappointment.

Nursery, Hackney, April 5, 1844.

EXHIBITION of CAMELLIA JAPONICA, or Japan Rose.—A Collection of these beautiful Exotics is now in bloom at CHANDLER & SONS' Nursery, Vauxhall. Admittance gratis.

SPLENDID LARGE, DEEP-BLUE ANAGALLIS and SUPERB CINERARIAS.—Plants of that large, splendid deep blue, full and complete round-petalled ANAGALLIS BREWERII being of a strong and vigorous habit, are well adapted for bedding out; 12*s.* per dozen.

SUPERB CINERARIA SEED, saved from the most esteemed named kinds, and other new and beautiful Seedlings, comprising every shade of dark and light blue, at 2*s.* 6*d.* per packet. Strong flowering plants of the above, 12*s.* per dozen. Applications, including Post-office orders, will be immediately executed.—Direct to MICHAEL BREWER, Sen., Cambridge Nursery.

SEEDLING FUCHSIAS, PHLOXES, and VERBENAS.

S. GIRLING begs to inform the admirers of the above, that he will have fine healthy plants of his superb Seedlings ready for delivery by the 20th of April. S. G. offers them with the greatest confidence, being well convinced of their superiority over any others he cultivated last year, which included about 100 varieties. The FUCHSIAS have been seen by Dr. LINDLEY, whose opinion on their merits will be found in the *Gardeners' Chronicle*, pages 528 and 561, of 1843, under the signature "*S. Girling.*"

FUCHSIAS.

CANDIDATE.—Deep crimson tube and sepals, petals bright violet-purple, reflexing so as to show the corolla. Price per plant, 5*s.*

GLOBOSA COCCINEA.—Tube nearly globular, dark vermilion sepals, and violet petals. 3*s.* 6*d.*

HERO OF SUFFOLK.—Dr. LINDLEY'S description of this is—"No. 5 is a handsome seedling, with short crimson vermilion tube and sepals of good substance, the latter expanding so as almost to reflex, after the manner of Magnifica; stamen and pistils much exserted." Price 7*s.* 6*d.*

PHLOXES.

KING OF THE WHITES.—The best white out; height, 3 feet. Price 5*s.*

SPECTABILIS.—Shaded lilac, very fine, height, 3 feet. 3*s.* 6*d.*

DRUMMONDI, var. SPLENDENS, a new annual of great beauty, being of the richest crimson scarlet, and quite circular in form. In packets of 12 seeds; 2*s.* 6*d.* per packet.

VERBENAS.

DEFIANCE.—Bright rosy pink; the best in its class. 3*s.* 6*d.*

TRESOR PARFAIT.—Bright violet purple, shaded with deep crimson; quite distinct from any Verbena known. 3*s.* 6*d.*

S. G. also begs to state that his Catalogue of Florist's Flowers is ready, and may be had on prepaid application; it will be found to contain nearly every novelty of the season, any of which S. G. will be happy to receive orders for, and which shall have every care and attention. The Fuchsias and Verbenas will be sent by post, free of charge, where preferred. The Phloxes are now ready for delivery.

Dane Croft Nursery, Stowmarket, March 23, 1844.

OLIVER'S "YOUNG HEIR" Dahlia.—To be sent out the first week of May, at 7*s.* 6*d* each.—A. OLIVER begs respectfully to call the attention of Dahlia-growers to the above Seedling, which gained prizes at the following Open Shows:—Fetton, Sept. 27th, 1842, First Seedling Prize; Fetton, August 31st, 1843, an Extra Prize, Nine Blooms; Fetton, Sept. 28th, 1843, First Seedling Prize, Nine Blooms; Alnwick, Aug. 29th, 1843, in the first stand of 12; also the Premier prize, Self colour; also the First Seedling Prize, Five Blooms. The above DAHLIA is one which the Advertiser flatters himself will give every satisfaction to purchasers, being a free bloomer, and never showing the eye; good petal, good centre, first-rate outline; colour, rosy crimson, height, from 3 to 4 feet. A. OLIVER would take one-half in plants from the Trade. The following Nurserymen in the north will be able to supply plants, viz. NEWTON, Newcastle; JANSON and FINNEY, Gateshead; HANCOCK and SON, Durham.—Eslington-house, Whittingham, Northumberland.

NEW AND CHOICE FUCHSIAS, VERBENAS, PETUNIAS, Sold by WARNER & WARNER, SEEDSMEN, 28, Cornhill, London.

WARNER & WARNER beg to inform their Friends they can supply all the varieties of FUCHSIA, PETUNIA, and VERBENA now out, either in single plants or collections. They have also all the new CINERARIAS, CALCEOLARIAS, GERANIUMS, DAHLIAS, &c., now in cultivation.

Catalogues of the above may be had. Plants of the new black Nemophilia, 9*d.* each.—Agents for the late Mr. LOUDON'S works.

NOW READY FOR SENDING OUT.

YOUELL AND CO.,

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN; HIS MAJESTY THE KING OF THE BELGIANS; NURSERYMEN AND FLORISTS BY SPECIAL APPOINTMENT TO HER MAJESTY THE QUEEN DOWAGER.

A SELECT CATALOGUE of the NEWEST and VERY BEST VARIETIES OF FUCHSIAS, VERBENAS, PETUNIAS, CHRYSANTHEMUMS, & ANAGALLIS, offered by YOUELL & Co.

YOUELL & Co., in submitting their Catalogue of FUCHSIAS for 1844, take the present opportunity of drawing the attention of admirers of the above elegant tribe of plants, to their select and superb Collection. They have spared no expense in forming a selection of such as are really good, to the exclusion of many that are mere nominal varieties; and they would refer to the numerous testimonials of success which attended their mode of selecting, last season, collections for Amateurs, for competition at the various Horticultural Exhibitions throughout the kingdom.

YOUELL & Co. being the parties who first sent out per post, with safety, these tribes of plants, are desirous of calling attention to their advantageous method of executing orders, namely, that they will deliver them free of postage (on the receipt of a Post-office order), to any part of the United Kingdom, upon the following terms:—

12 Extra Fine varieties, 12s., the Selection left to Youell & Co.
12 ditto ditto 21s., the Selection left to the Purchaser.
50 Fine varieties . . 40s., the Selection left to Youell & Co.
50 Extra Fine ditto . 60s., the Selection left to the Purchaser.

With the exception of those marked thus. *

The plants are strong and healthy, and ready for delivery: thus ensuring to the Purchaser fine plants for competition in the ensuing season.

NEW AND SPLENDID SEEDLING FUCHSIAS.

* "FUCHSIA LINDLEYANA." This brilliant Fuchsia, the entire stock of which is in the possession of YOUELL & Co., is now for the first time offered to the notice of the public.

Its exceedingly large tube and sepals are of the most vivid vermillion, and excessively expansive, surpassing in brilliancy any hybrid that has yet been raised. It was exhibited at the London Horticultural Society's Meeting, Regent-street, and greatly admired, and was pronounced by all who saw YOUELL & Co.'s specimen plant to be the most dazzling object of this tribe they ever witnessed. The foliage and habit exceedingly fine, a most abundant bloomer, and will be found a desideratum to every collection. Plants will be ready for delivery by the first week in April, at 7s. 6d. per plant. Usual discount to the Trade, when not less than six plants are ordered.

YOUELL & Co., in calling the notice of Amateurs and others to the following seedling Fuchsia, raised in their nursery, beg to state that in the summer of 1842 they bestowed every care in hybridising the best varieties in cultivation, from which they succeeded in raising upwards of 3000 plants, to the flowering of which one house was entirely devoted last year. And although many varieties possessing superior claims to the attention of those cultivating this elegant tribe, were submitted for the opinion of Dr. LINDLEY, and most favourably noticed, yet YOUELL & Co. feel that, in making a selection of the following six varieties, to which a most accurate description is affixed, will prove not only satisfactory to the purchaser, but to themselves.

These are now ready for delivery, and as the stock is very limited, early orders are solicited.

* "QUEEN VICTORIA." Tube and sepals smooth, of a bright vermillion, corolla stout, long, of a fine purple rose colour, forming a good contrast, and of fine texture, price 7s. 6d. per plant.

* "PRINCE OF WALES." Tube and sepals rosy vermilion, the latter tipped with green, expanding well, and showing a fine corolla of maroon purple; price 7s. 6d. per plant.

* "PRINCESS ROYAL." Tube and sepals bright red, corolla large and peculiarly bright in colour; price 5s. per plant.

* "MARCHIONESS OF NORMANBY." This is a large and showy flower, measuring four inches from the commencement of the pod to the termination of the pistil, tube and sepals scarlet, corolla stout, having a tinge of purple on it, price 7s. 6d. per plant.

* "LADY ALICE PEEL." A flower of good form and substance, fine rosy red tube and sepals, the latter terminating in a decided green, corolla very large and stout, of a beautiful crimson purple; price 5s. per plant.

* "LADY WALSINGHAM." Tube and sepals smooth, of a rosy vermilion; the latter turn up, and expose the whole of the corolla, which is stout, and of a fine purple crimson; price 5s. per plant. When the six are ordered, they will be charged 1l. 11s. 6d. the set.

"FUCHSIA QUEREV." Quite new, very beautiful, and not yet out, tube and sepals large and stout, of pure white, showing a dark crimson corolla; price 10s. 6d. per plant; ready in April next.

Fuchsia Seed, saved from the best varieties, 6s. to 10s. per packet, with Directions for sowing, &c. &c.

VERBENAS.

*"MONARCH" (Youell's) is a delicate creamy white, surpassing in its size and fragrance every other variety; the tufts of bloom measuring from 3½ to 4 inches diameter, and will be sure to give satisfaction. Price 5s. per plant.

* "BRILLIANT," (Youell's). This fine variety is of the most vivid scarlet, equal in this respect to "Melindris;" the bloom, however, is three times the size, and very fragrant, and will prove most desirable in any collection. Price 3s. 6d. per plant.

*"ELEGANS" (Youell's), is a most interesting variety, being a delicate lilac, with a distinct white eye; flower large and fragrant. Price 3s. 6d. per plant.

*"SURPRISE" (Youell's), can be recommended as a variety completely novel, and one that must be cultivated in every collection, the colour being of the richest rosy crimson, or ruby, producing tufts of flowers of 3¼ ins. in diameter, and delightfully fragrant. Price 5s. per plant.

The above four varieties have been selected from upwards of 2000 Seedlings, and may be confidently relied upon as possessing superior claims, and will be sure to give satisfaction; are now ready to send out (post-free). If the four varieties are taken, they will be charged 15s. the set.

ARAUCARIA IMBRICATA IN POTS.

Recently planted most extensively at Her Majesty's Gardens at Windsor, and also at the Royal Gardens, Claremont, furnished by YOUELL and Co.

YOUELL AND Co., possessing the most extensive stock in the country of the above Splendid Hardy Ornamental Tree, beg to offer them on the following advantageous terms:—Fine robust 4-year old plants, 8 to 10 inches high, 10l. per 100, or 30s. per dozen.

Fine Plants of CEDRUS DEODARA, 2ft. to 2ft. 6 ins., 10s. 6d. each.

Great Yarmouth Nursery, April 4, 1844.

N.B. All Orders above £2 will be delivered carriage free either to London or Hull.

FASTOLFF RASPBERRY.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, THE MOST NOBLE THE MARQUIS OF AILSA, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c. &c.; as well as by the HORTICULTURAL SOCIETY OF LONDON.

YOUELL AND CO. have much pleasure in announcing they are now supplying Fine Canes of the above highly-valuable and much-esteemed RASPBERRY, unequalled for the extraordinary size of its fruit and richness of flavour.

Those to whom Y. and Co. sent it last season have expressed their high admiration of its superiority over all other varieties, and has been awarded several prizes from various Horticultural Exhibitions during the season. As a proof they have not exaggerated its excellent qualities, fruit was submitted to Dr. LINDLEY, (see *Gardeners' Chronicle* of the 22d July last, page 503), whose opinion of it is as follows:—

"FASTOLFF RASPBERRY.—We have received from Messrs. YOUELL, of Great Yarmouth, fruit of the Fastolff Raspberry, and we find its merits all that has been stated in favour of its excellence. The fruit that we have received is very large, obtusely conical, and of rich flavour, far exceeding in this respect some other new and large varieties. The plants bear abundantly, and in long succession."

They also exhibited it on the 1st of August, 1843, before the London Horticultural Society, 21, Regent-street, to which a prize was awarded. It would therefore be unnecessary for YOUELL and Co. to recommend it more fully, or with greater confidence to the notice of the public, merely observing, that it continues in high perfection throughout the autumnal months, and has maintained its superiority in the most unfavourable soils and situations, and requires no other than the ordinary treatment of the old varieties.

Fine Canes are ready for delivery, and can be sent with safety to any part of the United Kingdom (on the receipt of a Post-office order), upon the following terms:—

		£	s	d
Packages containing 100 Canes	. .	2	5	0d
Do. do.	50 do. . .	1	5	0
Do. do.	25 do. . .	0	14	0

Package included.

The usual discount to the Trade where not less than 200 are ordered.

☞ CAUTION.—YOUELL and Co. deem it requisite to inform their Friends and the Public in general of the fact, that other varieties of Raspberries are being offered for sale under the title of "Fastolff," and such having no pretensions whatever to the genuine variety, they beg to state they cannot be held responsible unless it has been supplied from their Nursery; neither have they appointed any Agents for the sale of it.

TWO NEW AND SUPERB PICOTEES.—"LADY ALICE PEEL," 10s. 6d., and "MRS. BENYON," 10s. 6d. per pair.—These two splendid Picotees were raised by the Rev. J. Burroughes, of Lingwood Lodge, Norfolk, and were kindly presented to YOUELL & Co. by that gentleman. They have already obtained Prizes at the Norfolk and Norwich Hort. Soc. Exhibitions, and Y. and Co. feel assured that no further proof of their superior merit is necessary when they refer to the eminent raiser of them.

"LADY ALICE PEEL" is a large well formed flower, guard leaves and petals throughout of fine form and substance, and of the purest white; the lacing a delicate rose, and confined entirely to the edge. This is considered by all who have seen it to be superior to "Mrs. Barnard," or any flower of its class, and carries a beautiful long pod.

"MRS. BENYON," (red edge) also possesses every character of a first-rate Show flower, petals of splendid size, form, and substance, and the blooms expanding so correctly as not to require dressing, and carries a beautiful long pod.

FINEST CARNATIONS AND PICOTEES.

YOUELL AND Co. beg to refer the Readers of the *Gardeners' Chronicle* to their Extensive List, with Prices, of the above highly esteemed Flowers, which appeared on the Advertising pages, 706 and 707, of this Paper, of October the 14th, and will be found to contain every variety worthy of cultivation.

Prices as follows: £. s. d.

12 pair of good Show Sorts	. . . . .	1	4 0
12 ditto fine	ditto	1	10 0
25 ditto	ditto	3	0 0
12 ditto extra fine and very superior ditto, including a pair of that beautiful rose-flake, "Wilson's Harriet," and all first-rate Show flowers	. . . . .	2	10 0
25 ditto	ditto . . . . ditto	5	0 0

The selection being left to YOUELL & Co.

Great Yarmouth Nursery, April 4, 1844.

TO GARDENERS AND FLORISTS.

JAMES DICKSON & SONS, SEEDSMEN and NURSERYMEN, Edinburgh, beg to inform their numerous Friends throughout the country that they have been appointed Agents for the sale of WHITNEY'S CHEMICAL TRANSPARENT COMPOSITION for rendering Muslin, Calico, or Linen a suitable and economical substitute for Glass for Horticultural purposes. It has been very favourably noticed by Florists and Horticultural Societies throughout the country. Specimens may be seen at the Warehouse, 32, Hanover-street, or (the composition in use) at INVERLEITH NURSERIES.

Sold in Bottles (with directions for use)—pints, 2s. Cd.; quarts, 4s. 6d. each. Discount to the Trade.

J. D. and S. respectfully call the attention of their Friends to their NURSERY AND SEED CATALOGUES, which may be had on application.—April, 1844.

T. PEARSON begs to inform his Friends that he has lost the greater part of his stock of PANSIES, and cannot supply any sort at present except "Black Prince" and "Agnes," either of which will be sent post-free at 2s. 6d. each.

Chilwell Nurseries, near Nottingham.

FARM TO LET.

TO BE LET, with immediate possession, a very desirable FARM, containing about 436 Acres of Arable Pasture, and Sheep Walk well adapted for the Turnip system of Husbandry, the greater part of which is free from Tithes, lying within a ring fence, and situate in the parish of Battle, Sussex, and to which may be attached about 35 acres of good Marsh Land.

For further particulars apply to R. YOUNG, Esq., Solicitor, Battle.

Also, TO BE LET with immediate possession, a very desirable FARM, containing 254 acres of Arable and Pasture Land, including 10 Acres of Hops, in the parish of Battle, Sussex, to which 34 Acres of rich Marsh Land may be attached. Apply as above.

TO GENTLEMEN, FLORISTS, and OTHERS.

MESSRS. PROTHEROE AND MORRIS will submit to public competition, at the AUCTION MART, Bartholomew-lane, on THURSDAY, APRIL 11th, 1844, at 12 o'clock, about Three Hundred Pair of PICOTEES, the surplus stock of a first-rate collection. Also, a choice assortment of DAHLIAS, FUCHSIAS, GERANIUMS, and other flowering Plants.—May be viewed the morning of sale. Catalogues may be had at the Mart, and of the Auctioneers, American Nursery, Leytonstone.

HORTICULTURAL SOCIETY OF LONDON.—Notice is hereby given that the EXHIBITIONS of FLOWERS and FRUIT, in the Society's Garden, in the ensuing season, will take place on the following Saturdays, viz.—May 18, June 15, and July 13; and that Tuesday, April 16, is the last day on which Tickets are issued to Fellows of the Society, at 5s. 6d. each.

EXHIBITIONS OF FLOWERS, &c.—REGENT'S PARK.—The following are the Days appointed for the Exhibitions of PLANTS, FLOWERS, and MICROSCOPES, in the Gardens of the ROYAL BOTANIC SOCIETY OF LONDON, this season:—
TUESDAY, April 30,
TUESDAY, June 4,
TUESDAY, July 2, 1844,
When Prizes, exceeding 900l., will be distributed. Tickets for admission may be had, by orders, from Fellows or Members, at the Office, in the Gardens; price, on or before Saturday, April 13, 4s., after that day, 5s., except on the Days of Exhibition, when they will be 7s. 6d. each.
Schedules of Prizes and further particulars may be had at the Gardens. J. D. C. SOWERBY, Secretary.

FLOWER-SHOW.—The Annual Flower-Show, under the Superintendence of Mr. J. T. NEVILLE, of Ebenezer House, Peckham, will be held in the Grounds of the Almshouses of the Butcher's Charitable Institution at Walham Green, Fulham, at the latter end of June or beginning of July, of which urther notice will be given. JAMES NEES, Secretary.

ANY PERSON having healthy young plants of THE CITRON (Citrus medica), THE LIME (Citrus acida), THE SHADDOCK, (Citrus decumana), or any of the larger fruited Citrus tribe, may hear of a purchaser, by addressing a line to A. Z., 5, Charles-street, Covent Garden, stating size, price, &c.

The Gardeners' Chronicle.

SATURDAY, APRIL 6, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Friday, April 12	Botanical	8 P.M.
Tuesday, April 16	Horticultural	3 P.M.
	Linnean	8 P.M.
Wednesday 17	Society of Arts	8 P.M.
	Microscopical	8 P.M.

A Fox, says the fable, having lost his tail, persuaded his companions that tails were useless, and thus it was that bobtails came in fashion. Something of this, sort must have happened to the early Pine-growers or they never could have fallen upon the strange plan of cutting off its roots to make the Pine-apple grow The preservation of roots was found difficult with the old and inefficient modes of obtaining bottom-heat; and therefore roots were voted useless.

Cut off all roots that are not fresh and healthy, says Speechly; away with straggling roots, writes Nicol; disroot, disroot, cry half-a-dozen more, for roots are only annual things, and of no use to Pines after they are a few months old. Even Baldwin, with all his skill, could not perceive the error of the practice, although he confined his disrooting to the time when his successions were taken out of the tan and transferred to pots; and Mr. Glendinning, a still better authority, speaks of disrooting as a beneficial practice; adding, however, that it suits Queens better than the black sorts. There was, however, an exception to this singular practice, in the person of Griffin, the gardener to Mr. Samuel Smith, of Woodhall, who never would allow healthy Pines to be disrooted at any time, and who beat all his contemporaries in the magnificence of his fruit, although he was some way behind the Bicton and Longleat Pine-growers of the present day.

We should be greatly puzzled to find a reason for the practice of cutting off the roots of the Pine-apple, unless it was that as the imperfect mode of obtaining bottom-heat was continually leading to the destruction of roots, and nevertheless the plants continued to grow, it was thought that the roots could be of no use, and were better removed. Just as with the Orange-tree, which, because it will bear a great deal of cold, hunger, and neglect without perishing, some people fancy cannot well have too much of such treatment. "No plant whatever that I know of," says Mr. Barnes, "is subject to more unnatural treatment, and scarcely any other plant would endure half so much ill-usage, without dying altogether. The Pine-plant is something like that unfortunate beast the donkey,—it will endure a wonderful deal of ill-usage before dying or giving in altogether."

It may be, too, that the fibres of the Pine-apple plant have been thought to be merely annual, as is even now imagined to be the case with the Strawberry; although the most common attention to facts would show that this opinion is entirely unfounded. Mr. Barnes has sufficiently exposed this prejudice in his capital paper in the "Gardeners' Magazine;" and more recently, Mr. Hamilton, whose work on Pine-growing was reviewed the other day, has devoted a chapter to the exposure of this common and fatal error. In short, it would be an affront to our readers to dwell further on that point. Disrooting will therefore be regarded hereafter as the sure mark of a bad Pine-grower; and the destruction of roots by accident in Pine-houses will be the knell of the credit of either the gardener or his apparatus.

One of the soundest maxims of cultivation is—"*Never to allow a plant to receive a check;*" to keep it growing steadily during the whole period of vegetation—to let it sink gradually to rest—to maintain it in its state of torpor without disturbance—and to rouse it gently into activity when its allotted season shall have returned. This principle is of *universal application; there is no known or probable exception to it;* and every deviation from the rule is of necessity attended more or less with injury. The odd thing is, that Pine-growers should have generally admitted its importance, and yet not have perceived that a destruction of roots must be the severest check that a plant can well receive. Checks are indeed the greatest of all the causes of mischief in Pine-houses; crowds of suckers, a fence of gills, a disproportionate crown, and similar things, arise from that circumstance; and when once they appear, good-bye to good fruit. Disrooting is the prolific mother of them.

As we have no intention of returning to this subject for the present, we may as well mention Mr. Barnes's method of preventing the excessive growth of Pine-crowns, when by any accident a plant will try to produce them. It must be obvious that, if the Pine-apple plant has to feed both its fruit and a huge tuft of leaves on the top of it, (which, as our clever friend truly says, look like a baby's head with a man's hat on,) the nourishment which the plant is capable of yielding must be divided between them, and the man's hat will be formed at the expense of the baby's face. To prevent this, from three to six days after the blooming is over, he thrusts a small knife into the centre of the crown, and gives it a twist, when out comes the centre of the heart, which checks growth without disfiguring the plant. "The fruit taking the advantage, improves in swelling amazingly, and when finished, has a nice neat little crown on it, from 2 to 3 inches high, looking, in comparison, like a well-fed happy Englishman, with a becoming hat on his head." Speechly adopted a similar practice with suckers, in order to stop their growth.

THE next faculty which ought to be found in the mind of the Landscape Gardener is that of Imitation. We all know how readily this faculty runs into abuse when powerful, and not restrained by a sense of propriety. The proper exercise of it, in the case before us, is to imitate Nature—to ask, in all cases, what would Nature do? To be able to answer that question, the Landscape Gardener is supposed to have followed the advice formerly given, to examine Nature in all her aspects, and to take heedful note of them. A clever man, on looking at a scene to be improved, can form in his mind, almost instantaneously, a view of what is required; he can see at once what the execution of his design will effect, if well carried out. Having made himself acquainted with every kind of tree and shrub that may be available, its habits, size, colour, style of growth, &c., he knows what to select, and what will suit the soil and climate. The knowledge he must acquire, in order to enable him to imitate Nature—to make Art her handmaid, is extensive. The imitative power is indispensable; but there must be also a discriminative power, to hinder it from misplacing imitations. This faculty occasionally leads to very great absurdities; and yet we should consider its gratification, and not laugh at its votaries, though, to our taste, they may have spoiled what might have been rendered agreeable.

The faculty we are next briefly to consider—that of Construction—frequently helps Imitation into the ridiculous. We recollect having somewhere seen a mass of rockwork on a great scale—a little mountain, precipitous all round, and broken through by ravines, &c.; it was quite an expedition to get up to it and travel over it. But it was out of place. It is very proper to give to rock-plants a suitable dwelling-place in a collection; but where there are no rocks, imitations of them are absurd. If they exist on grounds that are to be ornamented, rock-plants may with perfect propriety be made to grow upon them. Any feature that is grand in Nature cannot be imitated with effect where the general scene is not grand; and where the scene is naturally grand, imitations of grandeur are not needed. Unless art can be effectually concealed—unless all objects be absent that can suggest it to the mind, trouble and expense are thrown away on imitations. There are many circumstances which render art essential, and certain forms imperative; but there is some great purpose to serve, which cannot be well served without a degree of formality. All that can be done in such cases is, to avoid formality as much as possible, and to render things not positively disagreeable.

It is only with great features that Landscape Gardening has to do; and little matters may be treated in a little manner. The symmetrical is allowable, and even necessary, when we come to minor concerns. The faculty of Construction undoubtedly operates in Landscape Gardening, though, apparently, the practitioner has only to design; but in designing, the execution of the design is kept in view, else schemes might be propounded the realising of which might be impossible. It appears to facilitate the conception of how a thing may be done, and likewise how it ought to be done, when more ways than one of doing present themselves. It is intimately connected with what is called intuition, and may possibly be identical with it, for everything is constructed in the mind before the hand is set to execute. The analysis of mental power is a very interesting subject; but it would be out of place to enter on it here.

Although mere Light and Shade are necessary to bring out striking effects, Colour must be attended to. Light and Shade, we all know, when the sun shines, vary every moment; and therefore it becomes a study so to assort objects within range of the principal point of view as to bring out various good effects. Not only must we regard the diurnal motion of the sun, but his position in the ecliptic, so that when he is at various elevations and positions light may strike and shadows spread out where they may make the strongest impression on the eye. This is a point not much attended to, but one of very great value, and well deserving the closest study by the Landscape Gardener. Frequently, the admission at a particular spot of a mere streak of light enlivens a whole scene and excites the highest admiration. Sunshine through trees, when the orb itself is concealed and the rays are penetrating a thin shower falling among them, produces at times delightful effects.

To enumerate all the effects that have occurred to us in rural scenery of various kinds, especially that denominated the romantic, might occupy a goodly volume. It is impossible to exhibit an effect and to analyse the manner in which it is brought about without the help of drawings and diagrams. With a few observations on colour, and remarks on one or two collateral subjects, we shall in our next conclude what we have to say.—*G.*

FAMILIAR BOTANY.

MORPHOLOGY.—No. X.

> Come sweet-lipped Zephyr and Favonius, bland!
> Teach the fine seed, instinct with life, to shoot
> On Earth's cold bosom its descending root;
> With pith elastic stretch its rising stem,
> Part the twin lobes, expand the throbbing gem.

IF the power of the Creator is wonderfully manifested in the formation of the embryo plant, out of mucilage and just-born cells, how much more admirable is the quality implanted in that embryo of developing itself into a perfect being! How marvellous the impulse which causes it to burst through the sides of its early tomb, to awaken by degrees from a death-like sleep, never again to rest, and from a wan and torpid grain to spring into that ever-changing, never-resting, gay and gaudy thing—a plant! Let us observe what we are permitted to know of the first changes that the little embryo undergoes; and for this purpose let us take the garden Mustard.

When the embryo of the Mustard is at rest it is yellow, and consists of two plano-convex scales of the consistence of an almond, upon which the radicle is folded down. The moment it begins to inhale the breath of life it softens, lengthens, bursts through the seed and begins its first change. This consists in a lengthening upwards and downwards of the small cylindrical space lying between the point of the radicle and the base of the scales; and its effect is to produce a white thread, the loose end of which forces its way downwards, drinking eagerly the moisture of the soil, while at the same time the other end rises upwards and carries the scale-like *cotyledons* into light and air; and while they *thus are rising* upwards, their solid contents are dissolved and converted into bland milk, which flows along the thread (which is the axis of growth) and sustains it in its growth, as a mother nourishes the infant at the breast. But in effecting this important purpose the scales are gradually metamorphosed, and from minute fleshy plano-convex yellow bodies they change into large thin roundish green lobes having all the texture and character of a leaf. Here, then, is a direct alteration of one thing into another wholly unlike it. The cotyledon grows into a leaf; therefore the cotyledon was a young leaf.

Next observe the garden Cress. It, too, goes through a similar series of changes in its earliest growth. The yellow fleshy scales of its embryo extend into long-stalked narrow lobes of a bright-green colour exactly of the nature of the future leaf; and, in order to show still more distinctly the identity of their nature, sometimes they are split into three pieces, just like those of the leaves to be subsequently produced.

It is true that this curious change does not take place in all embryos. In the common Pea, for example, the scales never alter their original appearance, but remain in their subterranean abode, shrivelling up and not enlarging; a circumstance which is possibly owing to their containing a much larger quantity of solid matter than the Mustard and Cress, and the conversion of which into fluid nutriment is so slow and difficult as to require, for chemical reasons, a continual detention in obscurity. But it is a principle in philosophy, which cannot be shaken, that *what is true of an organ in one plant, is true of the same organ in all other plants;* and, therefore, if it can be proved that the cotyledons of the Mustard and Cress are imperfect leaves, those of the Pea must be so regarded also. Not that it is absolutely necessary to have recourse to such reasoning in order to sustain the proposition; on the contrary, from the Pea, turn to the Kidney Bean, and therein will be found the most conclusive proof. The Kidney Bean is, in many respects, of the nature of the Pea; its embryo scales are very thick, hard, and fleshy, and slowly dissolve their solid contents, so that they have little power of thinning, expanding, and changing. They, however, differ from those of the Pea in this, that they do become green, are partially

thinned, acquire a small leaf-stalk, and actually reach an intermediate state between that of the true leaf and cotyledon.

And always thus does the young plant struggle into existence, proceeding from one state of perfection to a higher, or, as Morphologists say, from imperfection towards perfection—terms that have been cavilled at, and stigmatised as atheistical! but not used irreverently, or in the sense of materialists. It is, doubtless, true that an egg is perfect as an egg, and so is a seed as a seed; but that man must have a strangely-constituted mind, who cannot see that an egg is less perfect than the bird which is hatched within it, or a seed less perfect than the tree into which it grows. Those over-zealous persons, who, in their diseased imaginations, fancy they perceive in the Morphologist a latent Materialist, themselves exhibit the most enormous ignorance of the high attributes of the Creator. It is not necessary to be always talking of a great First Cause. In considering the works of Nature, we always deal with the facts that are plainly before us. By all men of sense it is *understood* that in speaking of natural phenomena an acknowledgment of the power that produces them is *implied*. "Il est certain," says an eminent philosopher, in writing of such things, "que tout cela est automatique; il n'y a point là d'intelligence ni de volonté. Mais derrière cet être inintelligent se trouve l'intelligence créatrice, qui a établi les admirables machines végétales qui exécutent ces mouvemens automatiques, tous dirigées vers un but indiqué par les besoins de la plante." We recommend this sentiment to the consideration of a class of writers, to whom, if we have sometimes alluded, it has been for the sake of what, we presume, are their good intentions, but certainly not for their intelligence and sound judgment.—*R. E.*

Erratum in last Number, p. 197, line 1 from the bottom, *for* "proportion's" *read* "perfection's."

FUCHSIAS.

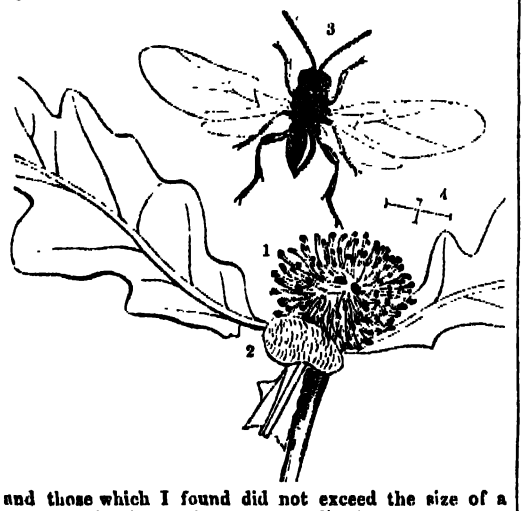
(*Continued from p.* 195.)

The last paper contained remarks on the means of obtaining an accumulative growth from one-year plants, or those potted the previous autumn, such being generally found in a state unsuited for another season's growth. The principal points were, to obtain an increased circulation of moisture by enlarging the bottom cavity of the ball externally, and to reduce the terminal shoots to a proportion commensurate with the general vigour and habit of the plant.

The treatment required for young plants, as cuttings of the current season's growth, differs in some respects. When such plants have been duly attended to in their removal from the store-pot, it is well known that their growth is more uniform and accumulative than those which have received a previous and premature rest; consequently the period of their removal from 60-size pots to larger, is limited in proportion to their condition and the habit of the variety. Nevertheless, if the cavity at the bottom is such as to indicate an impeded circulation in consequence of being closed by the position of the bottom potsherd, the cavity should be partially enlarged, as before recommended, and after the first or second top buds are pinched or cut off, it may await the fuller formation of its side or axillary growth previous to being shifted to a large 32 or 24-pot, into similar proportions and qualities of soil, as before stated. If the plants have already expanded their buds from the base of each leaf, they should be immediately shifted; and, when established, the top bud may be taken off, or more, as the variety may require.

From these remarks it may be inferred that plants, received in thumb-pots, should, if four joints long, be divested of the top bud a week or ten days previous to being removed to small or large 60s. The reasons for this are, that, as it is probable that plants when exposed to such small portions of soil are likely to be subject to opposite extremes of temperature and of moisture, so as to reduce their constitutional vigour below the possibility of accumulating it under such conditions, it is essential to shift them in proportion to their strength, that the cultivator may start them into such a growth by uniform proportions of soil, &c. (§§ 8, 9, and 10), as to enable him to give a final shift, or potting. This appears to be an essential condition of cultivation, in accordance with the principle, that "there is no arrangement of soil essential to the perfect condition of a plant, which is not proportionately essential throughout its whole period of growth." It is therefore assumed that all plants should be brought to the highest possible vigour, compatible with their existing conditions, previous to being exposed to the intense agencies of heat, moisture, &c.

With respect to the removal of foreshoots, or top buds, in order to induce a freer growth below, the following opinions are offered:—Where the buds are bursting from the base of the plant upwards, their perfect formation depends upon the removal of the plant to a larger amount of soil from the time of their first appearance, and a strong exposure to light, heat, and other essential agencies, it being understood, that to obtain splendid growth from a plant of one stem by causing an expansion of growth from the base upwards, in proportion to its height, is much more difficult than a similar width of growth from a plant of two or three stems. The first implies an approximation to its conditions of growth in nature, by very ample and uniform proportions of soil, with appropriate exposure during the first stages of growth, aided by partially inverting the leading shoot to retard the vertical flow of sap; while the second instance is illustrative of the conditions of growth by art, which obtains by a comparative result the intervention of many causes, which the former obtains by less. The first forms, in its first growth, the basis of ultimate vigour; the second reaches it by successive efforts, each exerting a negative influence on the one which preceded it.



Heath-mould has been recommended by some growers for the cultivation of the Fuchsia. I have no wish to underrate the value of this material; but when it is remembered that the qualities of Heath-mould vary as much as the indefinite qualities of loam, it must be admitted (apart from the fact that, whilst there are several natural orders of plants, to the cultivation of which Heath-mould is indispensable, there are many others, on the contrary, to which it is in no respect essential), that its application, in many instances, will depend upon its prepared texture and quality. Vegetable matter, in a highly decomposed form, being the basis of Heath-mould, is capable of holding nutritive properties longer than other soils, where silex abounds; and it is probably this quality which gives it its value in the Vegetable economy, viz. of maintaining longer than others an equilibrium of moisture in plants whose external organs are less capable of absorbing aliment from atmospheric and solar agencies.—*W. Wood, Pine-apple Place.*

(*To be continued.*)

ENTOMOLOGY.

Cynips Quercus Castaneæ (*the Chesnut-fruited Oak-gall-fly.*)—I have already described various galls, and the insects inhabiting them, and lately some of those created by the Aphides or Plant-lice, which excrescences are not genuine galls; and of those Hymenoptera, which are allied to the species that cause the galls of commerce; the histories of three interesting varieties have appeared in this Journal,* viz., the Oak-spangle, the Parasol-gall, and the Root-gall flies. I have now the pleasure of contributing another species, which does not appear to have been noticed in any work; and I shall feel obliged by any information regarding it, should it be discovered in this country. I unexpectedly met with these curious galls last year in the month of August, in the beautiful park and plantations near Florence, called the Reali Cascine; some Ivy was twining round the Oak which produced the galls, and at a short distance I imagined they were the flowering buds of that creeper, and it was quite accidentally that I discovered my mistake. On mentioning the subject to my friend, Professor Passerini, he informed me they were not unfrequently found in the country around Florence, and that when they were sufficiently abundant to attract the notice of the common people, they gave a singular explanation of the apparent phenomenon, namely, that the Oaks had been impregnated by the Spanish Chesnut, whose spiny young seed-vessels, these galls certainly in some measure resemble.

Here we have another instance of the absurd errors into which persons fall, from their total ignorance of the laws of Nature, which might be easily remedied by making Natural History a branch of education. I am ready to acknowledge that these curious vegetable productions were quite unknown to me, but suspecting they were the nidus of some Cynips, I gathered a few; indeed they appeared to be very scarce at that season, for I could find none on any other Oak-trees; and last February I had the satisfaction of breeding nine specimens of the fly from one of them. These Oak-galls (fig. 1) are green,

and those which I found did not exceed the size of a common Hazel-nut; they are covered with erect filaments, rather flattened, especially towards the tips, which are clubbed, of a pitchy colour, and apparently viscid; they are formed on the sides of the twigs, and are probably produced from the small buds at the base of the leaves; there were also two kidney-shaped galls arising from two other buds (fig. 2) in the branch figured; these were of an ashy-brown tint, partaking of the colour of the Bark, with smooth spots, but they have produced nothing; indeed they appeared to be solid, and were as hard as a knot of wood; yet I do not feel certain these may not be the nidus of the males, from which that sex would issue in a natural state, for, the leaves falling to the ground in the autumn, they would be kept moist during the winter, which would enable the larvæ to feed, and the flies to escape at the appointed time. This, however, is mere conjecture; and it is possible that the male eggs may be deposited in separate buds, producing distinct galls, and that they are generated at an earlier or later period; however that may be, all the specimens I have bred are females, and such is usually the case; for out of hundreds of flies that I have obtained from the galls of Cynips Rosæ and C. Quercus radicis, I never yet bred a male. Two dark spots are exhibited in the gall (fig. 1), through which the gall-flies made their exit, by eating their way out, and there were seven other holes in different parts, proving that the cells are separated, and that each insect had to perforate its case as soon as it hatched, so that the last was not able to avail itself of the previous labours of its associates.

The female fly is similar to others of the same genus, but not being identical with any I have seen, I have named it Cynips Quercus Castaneæ, in allusion to the galls resembling the young fruit of the Spanish Chesnut. It is black, the antennæ are slightly clavate, and about as long as the head and thorax; they are composed of 13 small joints, the basal one being the stoutest, the second much smaller and oval, the third the longest and slender; the apical joint is conical; the head, thorax, and scutellum appear griseous, from the short gray hairs which are scattered over those parts; they are all minutely and thickly punctured; the eyes are oval and lateral, and on the crown are three ocelli, forming a tolerably large triangle; upon the thorax are four longitudinal grooves, two in front parallel, with one on each side, curved next the collar, and extending to the scutel, where they approximate, and nearer the lateral margin is a short one; the scutellum is nearly orbicular; the abdomen is rather smaller than the thorax, very glossy above, ochreous beneath, of an oval form, the apex conical and pointed; the ferruginous ovipositor is concealed beneath; the wings are pubescent, the upper ones, as usual, are very long and ample, the nervures are bright brown, with a minute triangular cell on the disc; the socket at the base is ferruginous; the inferior wings are small and nerveless; anterior legs ferruginous, the thighs partially, the apical joint of the feet entirely, pitchy; the other legs are of a deeper rust colour, the hinder the longest and stoutest; the coxæ are large, and piceous at the base, as are likewise the trochanters and thighs; the tibiæ and basal, as well as the apical joint of the tarsi, are blackish (fig. 3). The cross-lines show the natural size of the female; the male is unknown.—*Ruricola.*

* Vide vol. i. p. 732; vol. ii. Dec. 24; and vol. iii. p. 52.

ON THE CULTIVATION OF GRAPES IN POTS.

(*Continued from page* 197.)

After potting, the plants should be placed in some house or pit where a temperature from 60° to 80°, or 85°, is maintained; they should also be so arranged that the shoots as they advance can be trained immediately under the glass, and be exposed as much as possible to the light. The front kerbs and back shelves of Pine-pits are suitable places, and the partial shade that the Vines afford benefit the Pines during three or four of the summer months. Where there is only a Vinery they may be trained between the permanent Vines, or in any other place where the cultivator can make room for them. As the shoots advance train them carefully, and stop the laterals as they appear. When first potted the plants will want but little water, but it must be gradually increased as the pots become filled with roots; they will then require it regularly during their growth, and manure-water may occasionally be given, although the quantity they demand the first season is small in comparison to what they require afterwards. The most suitable length of cane for pots is from four to six feet, but if from any peculiarity in the house, in which they are to be fruited, a longer length may be required, they should be left accordingly, as the Vine will grow strong enough for fruiting, 8, or even 10 feet long. After it has grown a foot more than the length required the next season, it should be stopped; three or four of the upper laterals, however, may be allowed to grow at a few joints, to prevent the topmost eyes breaking. Manure-water may now be applied to cause the buds to swell, and care must be taken to preserve the principal leaves, as they are now performing a most important part in regard to the crop next season. When the wood appears to be turning brown (or ripening), water should only be applied to prevent the Vines flagging, the laterals should be taken off, and every means should be employed to ripen the wood perfectly. Indeed if it is not convenient to allow a large admission of air when they are growing, it would benefit them much by removing them to a cool house, where they would have the benefit of more air and a lower temperature at night. By the beginning of September, if the former directions have been followed, the Vines will be ripe enough to place out of doors. The north side of a wall is the best place, and the pots should be laid on their sides, and every means taken to throw the plants into a state of rest; the cultivator will thus find himself in possession of Vines which for strength and vigorous habits may justly be mistaken for older plants.

It will be seen, then, that the principles acted on above are, selecting properly-matured wood for cuttings—inserting only one eye in each pot to prevent any check to the plant in repotting—placing them at once in the pot in which they are to fruit—exposing them during their growth to the greatest possible amount of light you can give them, taking especial care to have the wood perfectly ripe, and inducing an early state of repose. But if the above mode of obtaining fruiting Vines for one year should be thought too troublesome, from the plants requiring bottom-heat during their first stage, the eyes may be planted singly, as before, in 48-pots, and set in any house or pit where there is a little heat; they will be longer, however, by this method in developing their roots, and may not want shifting into larger pots before May or June. When the plants may be shifted into 24s, in which they may remain through the season, in any house or pit in which room can be found for them, paying attention to watering, tying up, &c. They may be stopped when 2 or 3 feet high, and when the wood is fully ripened,

removed out of the house and plunged in any material out of doors that is a non-conductor of heat. In February or March cut these plants down to two or three eyes, shake them entirely out of their pots, and place them in similar sized pots to fruit in as the former ones, taking care to spread their roots (in potting) regularly through the soil, that when growth commences, each spongelet may be in immediate contact with food; this is a much better practice than placing them in a pot without disturbing the ball, as is often done. The same routine of management must be followed with these through the season, as recommended for the others. From the larger amount of organisable matter the Vine possesses by this mode of treatment, they will generally be found stronger than those raised the same year, and they possess the advantage of ripening their wood earlier in the summer. It will depend on the means the cultivator has at his disposal which plan he follows.—*John Spencer, Gardens, Bowood.*

Home Correspondence.

Grafting Pelargoniums.—In a late Number is an account of M. de Méline, of the Botanic Garden at Dijon, having grafted numerous varieties of Pelargonium on the same plant. There are very few plants that can be grafted with greater success than Pelargoniums, if the stock and scion be selected about the same diameter, and if the wood is neither too old nor too young and succulent. For the last ten years I have occasionally grafted some in August or September, using pretty well ripened wood of the same year's growth. I shall only detail one instance:—In August of 1842, I selected a plant of the Beauty of Ware, which had a single stem about a foot high, where it divided into several branches; these were cut back to about three inches long, and in ten days afterwards they were grafted with eight different sorts. They were done after the manner of whip-grafting, and tied with bast and clayed, over which was put a little moss, to keep the clay from cracking, and to preserve the whole in a moist state, being occasionally sprinkled with water. The plant was placed in a shadowy part of a vinery, and in a month every one of the grafts had begun to grow. The plant was then put into a cold frame for a few days; it was then taken out of the pot, and all the earth being shaken from the roots, it was repotted in fresh soil, and received the same treatment as the other Pelargoniums. Two of the grafts were broken off by an accident, the other six flowered well in June and July. In August the branches were again cut back, and ten more varieties were grafted on it, including Smith's Superb Scarlet, Carnation Scarlet, Frogmore Scarlet, and the old variegated-leaved Scarlet; the last two failed along with two of the other sorts. This, perhaps, was owing to the plant having been placed in a shady place out of doors, immediately after it was grafted, where it remained until October, when it was placed in the conservatory. In December there were 13 varieties growing on the same plant, which will be a novelty when in flower, having so many distinct colours, Smith's Superb Scarlet forming the centre. I have observed that weak growing sorts grow stronger when grafted on robust kinds than on their own roots.—*James Alexander, Heath Farm, Athy.*

Gold Fish.—In this neighbourhood, every pond that holds water through the year is full of them, and instead of complaints of failure in rearing them, the great difficulty is to get rid of them. In every cottager's garden, where there is a dip-hole dug to the depth of four, five, or seven feet, there the fishes thrive and breed. In these ponds there is nothing but hanging grass and stones imbedded in clay or gravel to which the fish can attach their spawn, and yet they breed. My own pond, which is perfectly alive with Gold and Silver Fish, is about eight feet deep in the centre; it is made with chalk rammed, and has never had plants of any description put into it, yet waterweeds of various kinds grow in it in the spring and early summer, and then sink down; it is a pond for the cattle to drink at. At the drinking-places rough gravel and stones have been put down to prevent the cattle from poaching or breaking the ground upon any of the chalk; about 14 or 15 years ago it was mudded, and only a few stones returned to it. Several other ponds near me, by the road-side, used as drinking places for cattle, are full of Gold and Silver Fish; nothing is ever done to them by way of nurturing the spawn; the pond in the centre of Epsom is also full. These ponds are all mudded every three or four years, and the fish taken out and sold or thrown away, except a few that are kept in tubs until the rain falls in sufficient quantity to allow them to be returned. On Epsom Common are several large gravel-pits full of fish. I would here observe, that none of these ponds are supplied by perennial springs; the water in them is either rain water, or water from land springs in the winter, or from both these sources. Gold and Silver Fish will not live any length of time in ponds in which there are springs, much less breed in them—the water is too cold; they fur with a kind of moss and die. The ponds I have mentioned have all of them stony or gravelly bottoms, and slope from the sides to the centre; the fish deposit the spawn on the pebbles or gravel in the shallow water, which being much warmer, from the greater power of the sun over it than the deep places required for aquatic plants, the spawn is more certain of being quickened into life. All who form ponds to keep fish in, contrive to have gravel or pebbles at the bottom, in the shallows, because this is the most sure method of succeeding. Another pond that I am acquainted with was made with clay, a little lime being mixed with it; it is full of large fish, but the sides being perpendicular, the fish do not breed well; its depth is three or four feet, and sticks are put in, to which the fish may attach their spawn; this pond is fed from another, where the fish breed abundantly, but it has plenty of stones as well as water-plants in it. The water feeding all these ponds is at times of a brackish nature; it runs over a soil impregnated with iron. I will describe four more ponds in which fish thrive and partly breed. The 1st and 2d are at Epsom, and are artificial; No 1 is made with tiles and cement, about two feet deep throughout, except near the edge, which shelves a little, and is supplied with water from a well in the chalk; when the water in the pond is getting low, a man pumps from the well into the pond. No. 2 is a small reservoir, about seven feet in diameter, and five deep; this, too, is supplied with water from a well in the chalk; the pond is cemented all round, the only places to which the fish may attach their spawn is the sides, and a small fountain in the centre; but in a pond like this it is advisable to put in a few branches of Willow to reach from the bottom to the top. No. 3 is formed like No. 2, only it is deeper by a foot or two, and is supplied with water from the New River; pieces of Willow and aquatic plants are put into it, and during the time I knew it the fish flourished. No. 4 was on the summit of the Gog-Magog Hills near Cambridge; it was a small basin, formed for the reception of the fish, and water was supplied to it from a well in the chalk; it was about a twelvemonth after I had sent fish to it that I saw them, when they appeared to be in good health, but had not then increased; the basin was too small, and too much shaded by trees to favour propagation. If any one is desirous to see fish and ponds, let them visit Epsom about the latter part of May and beginning of June; they will then see how ponds are constructed, and how the fish deposit their spawn, and any little boy on the common will catch them for sixpence per pair. If fish do not breed, the fault is either that they are all of one sex, or that the pond rests on a spring, and is too cold, or is not sufficiently shallow towards the edge; or there is a want of gravel, stones, or sticks in water sufficiently warm during the breeding season.—*J. Steele, Epsom.*

Morphology.—The structure and conformation of the vegetable world is a most interesting and curious study, and well deserves the attention of the botanist. The reduction of all the various organs and developments of plants to a few simple original forms, of which they are but modifications and degrees, has been effected by modern science, and has no doubt thrown great light on the subject. I would, however, beg leave to say a few words on what may be called the abuse of the doctrines taught by Morphology, or the utilitarian way (if I may be allowed the expression,) in which, by this method of explaining structural botany, the majesty of Nature is apt to be lost sight of, and some of her most beautiful productions attributed to mere chance. In the now generally received opinion, the leaf is thought to be the primary form of vegetable organisation, and all the other organs and parts of the plant (with the exception of the stem which produces the leaf) to be but leaves in a more or less developed state. But some writers on the subject go even further than this, and say (if not in precise words, at least by implication) that it is only by chance and casualty that any other organs than leaves and stem exist; that bracts, for instance, are merely immature leaves, which poverty of soil, or other causes, have prevented the plant from developing; or that flowers have been produced from leaves, merely by circumstances favouring their greater development. Now these assertions appear to me erroneous, and I think are at once disproved by the fact of the constant and unvarying arrangement of the different parts of plants by the hand of Nature. In the normal or wild state of any plant, we always find the various organs similarly disposed, and bearing the same relative position to each other. We find the leaf, the bract, and the flower, each occupying its allotted and certain situation. This would not assuredly be the case if their development was but the result of accident. I will admit that the structure of the leaf, the bract, and the flower, is essentially the same (and this seems to be now quite ascertained), but I would have things called by their right names, and I would deprecate the use of language calculated to derogate from the dignity and plastic power of Nature.—*Dendrophilus.* [Our correspondent evidently misunderstands the meaning of the Morphologists.]

The Penny Postage.—The facility, punctuality, and moderate charge at which letters and small parcels may now be conveyed from one part to another, even to the most remote village, hamlet, or peasant's cottage, must alike be beneficially felt by all; and in time will, I make no doubt, greatly improve and increase knowledge, the great bulwark of the country, by stimulating many to attempt writing that under the old system could not afford to pay the postage. Many a poor parent and distant child can now have the pleasure of corresponding with each other; merchants, tradesmen, publishers, and correspondents of all classes are alike benefited by the present reasonable and expeditious transit. To no profession has it opened up a wider field than to gardeners: it gives the opportunity of exchanging seeds with each other from different localities, comparing specimens, and getting them properly named, &c. They can also forward to each other any improved method they may have discovered in cultivating any kind of plant, fruit, &c.; and they can communicate their experience to some periodical, for the benefit of the public, who, if they think proper, may practise and improve on it; for it is to be observed that there is no method or system in practice, however perfect to appearance, that may not be improved upon, by the persevering and intelligent. At the same time I would observe, that a person that takes the opportunity of writing a practical article, which he considers likely to throw more light on the cultivation of any plant, fruit, &c., that he has himself been more successful in cultivating, or in bringing to a higher state of perfection than others, and attaches his name to the article, is certain to receive a host of letters; some wishing for a farther explanation, others observing that it is so different to what they have ever seen or heard of in practice, that they consider it is an impossibility to succeed, &c. Some again write for the whole article, as they have been informed that it has been published in some periodical or journal to which they are not subscribers. Nine out of ten of those worthy correspondents never think of inclosing so much as the penny postage stamp for the required information; thus it is not only an encroachment on a gardener's very limited time, but on his pocket likewise, if he should think proper to find paper, wafers, and stamps. To the correctness of this statement I have not the least doubt many can bear testimony, and like myself are deterred from adding their names, which is very essential to any practical article, in order to give it respect and confidence. Gardeners in general are not so well paid as to afford to answer a host of such correspondents, supposing they could allow their time to be encroached on by writing over again, what possibly cost them many years' anxiety, and ill-paid perseverance to obtain.—*Observer J.*

Double White Hepatica.—In a late Number it is stated that you are unacquainted with any Double White Hepatica. Being misled by Martyn's edition of the "Gardeners' Dictionary," I, for several years, endeavoured in vain to procure a specimen of it. I have, however, the certain evidence of a friend, that a pot of the double white, some years ago, was exhibited at a flower-shop in Bath, which the owner refused to sell for any money, alleging that he had never seen another; and in answer to some subsequent applications for a specimen, the gardener said that the plants had died without his being able to increase it. In Martyn's edition, above referred to, the double white is represented to be equally common with the double blue and double red Hepatica, and the error is continued in Rees' Cyclopædia; but no such mention of the double white variety is made in either of the original editions of the dictionary, and the following interesting suggestion of Miller's has been entirely omitted by Martyn:—"I have sometimes known the double blue sort produce some flowers in autumn, which were inclining to white, and thereby some people have been deceived, who have procured the roots at that season and planted them in their gardens; but the spring following their flowers were blue as before, and this is what frequently happens when the autumn is so mild as to cause them to flower; but whether the double white sort, mentioned in the books, was only this accidental alteration in the colour of the flower I cannot say, though it seems very probable it was, since I never could hear of any person who ever saw the double, white sort flower in the spring."—*L. W. D., Shelly-Hall.*

Celery.—I am induced to recommend a mode of cultivating this valuable esculent, which I practised last season with the most complete success. My gardener having mentioned that his supply of Celery-plants had run short of the expected demand on him, I told him to go to a marsh in his neighbourhood, on the banks of the river Lee, where the tide flows over at high water, and that he would find abundance of plants ready for his use, both of the red and white kinds, and to make trial of them. He looked astonished at my proposal, but seeing that I was in earnest and willing to take on myself the responsibility in the event of failure, he did as he was directed, and is now ready to confess that he never cultivated a better crop than the product of these wild plants, as he called them. Persons who eat of them at my table praised them not only for delicacy of flavour, but for freedom from hollowness in the heart, which was found in almost all the Celery of the past year in this quarter. My gardener is so well satisfied of the result of the experiment, that he does not intend sowing Celery-seed in a hot-bed as usual this season. It will be said in reply, such are not within the reach of many to procure; but where they are I can confidently recommend them. *En passant*, I may remark—"I do not consider the rearing of large Celery desirable," as Mr. Paxton and others observe.—*Coreopsis.*

Seedlings.—I have noticed that young plants in the seed-leaf, if deprived of their root and replanted, plunging them up to the cotyledons, and pressing the earth, which must be very fine, carefully up to the tender stem, will again strike root and flourish. This may be useful in the case of valuable plants, one only germinating perhaps out of the lot, and that damping or having been eaten off by insects close to the surface of the earth. It was first noticed in the case of a Balsam, afterwards with Anagallis and others. The fact may not be new, but is, at all events, worth knowing at this time of the year.—*Micklewell.*

Linnæan Botany.—On page 361 of the "Gardeners' Chronicle" for 1843, it is stated in a notice to a Correspondent that "The Linnæan system of Botany is not worth learning, and we cannot do you the disservice of recommending you a book on the subject." Now, if by this is to be understood, that a knowledge of the Linnæan system does not tend to explain the physiological structure of plants, to ascertain their medicinal properties, to assist the investigation of the laws of vegetation, to enable Botanists to declare the general nature of the soil on which plants are discovered; that, lastly, it does not allow the application of Botanical science to the purposes of Agriculture, the truth of the above statement is easily admitted. But if, on the other hand, we are to believe that Linnæus's system is abstractly bad, that the knowledge conveyed by it is not worth retaining in the memory, or that it positively misleads its followers, such a statement appears to be open to considerable objection. Superior as a natural system must always be to an artificial,

it still must be admitted that, considering the limited number of Phænogamous plants natives of Great Britain (for the natural orders of the Cryptogamic division are comparatively few, and generally known at sight) a person in this country who had not recourse to large collections, would scarcely be able to form any idea of a system guided and established by the principles of nature; the materials with which he has to work are too scanty, and allow not of a comprehensive comparison. There is nothing in the Linnæan system which is essentially incorrect; the knowledge gained from it is imperfect and unsatisfactory only. In the description of any natural order we are generally told the number of stamens and pistils; so that the number of these organs, even in a natural system, form two distinguishing characteristics of any given order. It would be well for any one, when studying an artificial system, to remember that this is not the Science of Botany, but merely an easy mode of discovering the name, and name only of the plants found in the particular place or country in which he might happen to be. And there seems to be no objection, in this sense, to the admission of the value of such a system. The pupil would consider that he was only reading the contents of, or introduction to a portion of a large volume, which he afterwards intended to study philosophically and in detail. There is no wish whatever to set up the old against the new system; at the same time it should be borne in mind that no new method is advanced by the depreciation of its predecessor. In a word, there seems to be no practical advantage in dissuading those from following an artificial, whose occupation and inclination would preclude the more laborious studies of a natural system.—*F.* [Our answer is, that Linnæan Botany teaches nothing but names, and them with less certainty and advantage than the natural system. It had its use in former days, but is now abandoned by all Botanists.]

Season for Shifting Plants.—Respecting the autumn-shifting of plants, "J. W. K.," at p. 102, says that "plants are in the habit of appropriating nutritious matter by their roots during the season of rest;" or, in other words, that their roots continue to grow while the head remains dormant. I have lately had an opportunity of testing the truth of this opinion. Having received a quantity of Pelargoniums from a nurseryman about the end of last November, and thinking the pots they occupied rather small, I immediately shifted them into pots two sizes larger; having been kept very cool, they have grown little. I examined them very lately, and I find in most instances, where few additional leaves have been formed, scarcely a single fibre has reached the outside of the ball (and yet the plants are perfectly healthy). I cannot comprehend how the formation of roots can take place, to any extent, without a corresponding development of leaves; we do, indeed, see in bulbs a disposition to form roots without any extension above ground; but this is contrary to what "J. W. K." assumes to be the case, which is, when plants are at rest, whereas this is when the bulbs are concentrating all their energies in order to produce leaves. I am decidedly of opinion that excepting where the one-shift system is pursued, no better plan can be adopted in the cultivation of greenhouse plants, than that of allowing them to fill their pots with roots by the end of October, and shifting them again about the middle of February, when the growing season commences.—*E. J.*

Yeast or Leaven.—The following recipe is known to make good light bread:—To 2 oz. of Hops put 8 quarts of water, simmer it four hours, until reduced to 6 quarts; thicken it with 2 lbs. of Wheat-flour, and stir into it two table-spoonfuls of moist sugar. Let it remain in an earthen pan until lukewarm, then add a tea-cupful of good fresh beer-yeast, and bottle it in wine quarts; each bottle must not be more than half-full, and two such bottles will leaven 13 lbs. or 14 lbs. of flour. It must be thoroughly well corked. The beer-yeast is required only for the first making. The second time it is made, a tea cupful of the old leaven should be substituted for the beer-yeast.—*K. O.*

Pruning Trees.—It is most extraordinary that the mode suggested in the *Chronicle* of pruning trees has not been generally adopted, since it appears that in the principality of Wales it has been practised 40 years with the happiest result. It recommends itself by its extreme simplicity, and by its accordance with plain, practical common-sense; and yet what (comparatively) little progress has it made amongst men who have an opportunity of seeing the advantages of the system at a trifling expense! But "they have eyes and see not." What number of acres does it require to make a wise-acre? About two years ago I got the ear of the bailiff of a gentleman who planted 12 acres when the common was inclosed. The trees required the knife; the bailiff saw the advantages of this method, and promised to set about it. That he might not be plagued by the ignorance or the obstinacy of the labourers, I took him a man who understood it, and was willing to undertake it almost without pay; for he had the sense to see that it would bring him into notice, and benefit him extremely. Notwithstanding all that had passed, the work was never begun, because the owner objected that the experiment should be made, and the plantation will be treated as all others in the neighbourhood have been, *i.e.*, neglected and spoiled!!—*A Fenman, Isle of Ely.*

Covering for Greenhouses.—A correspondent in the *Chronicle* recommends the use of prepared linen as a substitute for glass in frames, pits, and greenhouses. Plants require a pure light, and will not grow so luxuriantly if it is conveyed through a dense medium; if the top of a conservatory was covered permanently with anything to exclude the direct rays of light, the plants would be found to incline to the glass sides. The plan may answer as a temporary protection from frost, or to shade from the mid-day sun; but it would, in all probability, disappoint the amateur if he solely depended upon it instead of glass. —*Falcon.*

Functional Disease.—In the analogies made use of (p. 148, March 9), to illustrate my argument in favour of the possible existence of functional disorder independent of structural disease, I did not, as "Der Greif" supposes, overlook the difference between animate and inanimate machinery. But in treating of the phenomena of living organism, whether in its normal or abnormal condition, in our ignorance of the essential nature of the living principle, we can only reason of them with reference to the chemical and mechanical principles by which those phenomena are guided. It is the privilege of the living tissue to make these principles subserve its several purposes; but always in obedience to the laws which govern inanimate matter when moved by disturbing causes, whether of chemical or electrical affinities, molecular force, or any other moving power. Or, in other words, the only difference between the living organism and the dead is, that the former carries within itself the originator of its own movements, and to a certain extent the power of repairing its own waste; while the latter derives the same privileges from some extraneous agency. With this difference every animal organ is as much a machine for the performance of some chemical or mechanical action on the materials offered to it, as the merest engine of the factory or laboratory, and for such purposes is guided by the same laws. Premising thus much on "Der Greif's" objection to my mechanical analogy, I go on to observe that he does not seem to recognise the distinction which certainly exists in Nature between change of condition and change of structure. If it be maintained simply that disease arises from altered condition of an organ, then I concede the point, and there is an end of the matter. No one supposes that functional disorder can exist without altered action—abnormal motion. An organ may be over or undercharged with blood, may be over or underdone with nervous power or nervous electricity; there may be in it too much or too little combustion, for the healthful performance of its function, and yet its structure be unaltered. Just as a mill may be over or underdone with grist or with water, and stop, though all its wheels and cogs are in right order. There is still another and a better reason why functional and structural disease should exist independently. Every part of the animal organism is endowed with a double apparatus, or system of parts, the one subservient to its functional, the other to its material existence. There is not anything done in the animal economy that is not done by its peculiar instrument. The functions of an organ are maintained by nerves and blood-vessels, which administer nothing to the nutrition of that organ. Its powers are maintained, its waste supplied, its worn-out materials removed, by nerves, blood-vessels, and absorbents, distinct from and independent of the influences that determine function. The material existence of an organ may be maintained in perfect sanity; its supply and waste may go on, for a time at least, in perfect harmony, by means of the blood-vessels and nerves appropriated to its structure, whilst its functions may be increased beyond the ordinary rate, or altogether suspended. Every physiologist knows that the nerves of secretion in a viscus may be destroyed, and its functions lost, and yet that organ does not die, nor waste away, till long inaction has made it useless; and perhaps not then. Structural change, or organic disease, then, must be the work of the structural system. It may co-exist with functional disorder, and it cannot exist long without inducing it—for a faulty instrument must work badly. It may be induced by functional disorder, because inordinate or irritative action disturbs the healthy equilibrium of supply and waste—as an overworked engine soon gets out of repair. In fine, functional disorder may be of long or short duration,—it may come and go in a moment, because it is not structural. But organic disease cannot be established till some disturbance takes place in the nutritive apparatus appropriated to its maintenance, nor removed till the consequences of that disturbance are corrected.—*M. D.* [We trust our valued correspondents will agree with us, that it is better not to prolong this discussion, which may become inconveniently long.]

Hops.—It is my belief that Hops are absolutely necessary for the preservation of beer, but not at all essential for yeast. The flavour is dependent on an aromatic essential oil, which is dissipated by boiling, though the bitter extractive is obtained in solution. An infusion, however, will extract the aroma without much bitter principle. Now, a decoction of Hops will not keep long, any more than a decoction of Malt, but they contain very opposite constituents. Hops contain tannin, extractive bitter principle, wax, resin, and lignin: whereas Malt contains resin, gum, sugar, gluten, starch, and hordein. The antiseptic properties of the Hop, therefore, are evident, and, no doubt, after vinous fermentation of the two decoctions, a combination of constituents (notwithstanding the sugar, &c. of the Malt being converted into spirit) takes place, and the result is a liquid, which will keep for almost any length of time, if preserved from the action of the atmosphere. It is evident, from the common practice of brewers adding the Hops previous to fermenting the wort, that they do not prevent, nor even retard vinous, but undoubtedly they retard acetous fermentation; therefore yeast may be made with or without Hops.—*J. B. N.*

Rabbits.—I am possessed of a property, consisting of underwoods, arable pasture, and garden ground, adjoining to a gentleman who has large landed property, particularly 200 or 300 acres of underwood; and in which, both to my annoyance and injury, he suffers the breeding of rabbits to such an extent as to destroy acres of corn and grass of his neighbours, and he is deaf to entreaties to destroy them. As for myself and tenant we do all in our power to destroy them on our own premises; and he has suffered his keeper to take advantage of my tenant trespassing only about 20 yards out of my road to a bush in his hedge to shoot the vermin in my field at my desire, by laying an information through the Surveyor of Taxes, and fining him in the double penalty for carrying a gun. Can any of your correspondents assist me with advice how to destroy these rabbits? Traps, wires, guns, and dogs have been used to get them out of my premises, but I cannot devise means to keep them off. It would take a mile in length of netting to fence out, and net has been used round my garden, but they have eaten a thousand holes.—* [A good answer to this would doubtless be useful to others as well as to our unfortunate correspondent.]

Miscellaneous.—*A. H.* states that in Essex the Prunus cerasifera, commonly called the Myrobalan, or Cherry Plum, which bears so freely as a standard, is found valuable for the sake of the young fruit, which is used for tarts like green Apricots, and with about equal gratification to the palate.——*E. L.*, a known correspondent, informs us that he could have cut six fruit, averaging 15 inches long, from one plant of the Browston Stock Cucumber on the 21st of March; each fruit was from 14½ to 16 inches in length, making 90 inches of Cucumber from one plant in one day. He states that they were all good table fruit. The same writer says that from the same plant he lately cut four handsome fruit and a curious double one which, if considered as two, make six. The plant that produced these we understand is growing in a pit that was contrived by Mr. Mills, of Gunnersbury Park. It is worthy of remark that this same plant produced one of the fruit that won the first prize at Ipswich on the 8th of February, and it is still in full vigour. A fine specimen of the Browston hybrid, and also the double fruit, were sent to Covent Garden market, where they have been seen by many gardeners, who all consider them equal to any they have yet seen in the market this season.

Societies.

HORTICULTURAL SOCIETY.

April 2.—R. H. SOLLY, Esq., in the chair. A. Pryor, Esq., was elected a Fellow.—Mr. Hunt Grubbe, of Shirley, near Southampton, sent a specimen of slate wall contrived by him, which was stated to have the following recommendations. If placed direct with the meridian, and thus made to have an equal share of sun on both sides, it will ripen any fruit on either side earlier than the south side of a brick wall by means of the transmitted heat. It is not recommended as an outside fence, as it is liable to be broken; but chiefly for intersecting the interior of gardens in the place of dwarf or shelter hedges. It consists of squares of slate grooved into each other, and strengthened by piers or pillars, which are placed at certain distances—and, being built with circular and square bricks cemented together, are round and stand out a little from the wall. The trees are fastened to wires, which are fixed into the slate about six inches apart. Mr. Grubbe stated that this wall could be erected for 5½*d.* the square foot, being 1*d.* less than even a 4½-inch brick wall, which costs 6½*d.* the square foot.—From the gardens at Chatsworth were two bunches of West St. Peter's Grape, shrivelled, and in the condition of fine raisins, which Mr. Paxton stated to be of last year's growth, and to have been kept through winter at an almost nominal expense of fuel. The house they have been kept in was in a low situation, and therefore not well suited for late Grapes. Mr. Paxton considers it a better Grape than the Black Hamburgh; and if both have the same treatment, the St. Peter's will keep six weeks or two months longer than the Hamburgh. Along with these were also the following plants:—Dendrobium Paxtonii, a large specimen, with orange blossoms, having a black spot in the centre; also Eria excavata, cut specimens of Dendrobium Wallichii, D. cæruleseens, and Cœlogyne interrupta, the latter with pretty white and yellow flowers. A Knightian medal was awarded for the Dendrobium Paxtonii.—Messrs. Loddiges, of Hackney, sent Dendrobium macrophyllum in good condition,—this rare species is remarkable for the strong aromatic fragrance of its fine lilac blossoms. A Knightian medal was awarded for it.—From Mr. Green, gr. to Sir E. Antrobus, Bart., was a most beautiful large specimen of Erica aristata major, uniformly covered down to the pot on all sides with pretty carmine and white waxy blossoms; it was also feathered with healthy dark-green leaves to the very extremities of the branches. Along with it was a seedling Calceolaria (called zebrina), the flowers of which were of a bright yellow, beautifully spotted with brown; Amaryllis hybrida, and Boronia anemonefolia, the latter with pretty rose-coloured flowers. A Banksian medal was awarded for the Erica.—Mr. Jackson, of Kingston, sent Tremandra Hugelii, a greenhouse plant, with drooping star-like lilac blossoms, having a small dark spot in the centre.—From Mr. Fielder, gr. to W. Linwood, Esq., was a cut specimen of Phycella chloracra, a bulb sent by Mr. Hartweg from rocks near Saragura; the flower-stem that bore the handsome but not gaudy green, red, and yellow blossoms sent was said to have been 3 ft. 2 ins. high. —Mr. Robertson, gr. to Mrs. Lawrence, sent a collection of plants containing Cyrtopodium Andersonii, rarely seen in such perfection; an enormous specimen of Maxillaria Harrisonii in wonderful health; Brassia Wrayæ, a species from Guatemala; Oncidium ampliatum major; O. luridum; a Hippeastrum, and a well-grown plant of Erica Willmoreana. A Knightian Medal was awarded for the three first.—From Messrs. Henderson, of Pine-apple Place, was Odontoglossum Rossii, sent from Belgium under the name

of Oncidium Bergamia. From the same collection were Dillwynia tamarifolia, a scarce New Holland shrub, which has a gracefully drooping habit, and is a remarkably free bloomer; Brachysema platyptera; Epidendrum alcefolium; Boronia anemonefolia, and Dendrobium cruciferum covered with blossom. A certificate was awarded for the Dillwynia and Brachysema.—Mr. Ivery, of Peckham, exhibited seven seedling Cinerarias, and a plant of the new Nemophila discoidalis.—From Mr. Lee, gr. to P. Pole, Esq., was a Cucumber which measured 21½ inches long.—From the garden of the Society were the following plants:—Acacia hispidissima, Boronia anemonefolia, Begonia papillosa, B. acida, Columnea Schiedeana, the larger variety of Oncidium ampliatum, Acanthophippium bicolor, with curious yellow cupped blossoms, and Echeveria rosea, a greenhouse plant remarkable for its bright red leaves that are more conspicuous than the flowers, which are of the same colour. It was sent to the Society by Mr. Hartweg, from Mexico. It is not impatient of cold, having been sometimes exposed to a temperature as low as 35°; it will also, on the contrary, stand any amount of sun-light, and it keeps in bloom during the whole winter, so that it is a very useful plant for many purposes. With these was a flower of Aristolochia Gigas or "Pilate's nightcap;" a twining stove plant, which bears singular large concave blossoms having considerable resemblance to those of A. fœtens, but much larger, and assuming more the appearance of a cap.

Reviews.

Geology; Introductory, Descriptive, and Practical. By D. T. Ansted, M.A. 8vo. Van Voorst, London.

As far as we can judge from a single Number of 128 pages, this promises to be a useful work for the Geological student. The language is clear and simple, and the illustrations selected with judgment.

In describing the various conditions through which the crust of the earth has successively passed, the Author commences with the rocks in which the Geologist discovers the remains of extinct animals or plants, and he proposes to notice such formations in the order of their stratification,—that is to say of their antiquity,—deferring to a future part of his work the examination of those most ancient rocks which preceded the appearance of living things, and from the destruction of which the later rocks proceeded. We cannot at present judge how far this plan will prove judicious; at first sight it is open to obvious objections.

There is one point, however, in which Mr. Ansted seems clearly to have committed an oversight. At his 54th page he adverts to the importance of the statement that "fossils are characteristic of formations," an assertion which supposes "a degree of perfection in the application of Zoology and Botany to such fragmentary portions of structure, that the reader may fairly require some account of the successive steps by which the result was at length reached, and a connected view of the nature of the argument that has led to conclusions which, however viewed, are so exceedingly remarkable." And then he proceeds to give that account. But after sketching the nature of this kind of investigation in Zoology, he passes over the equally important and more difficult inquiry of the Botanist, with a short assurance that he will have some observations hereafter to make upon that subject. This is to us, we confess, a puzzle; if it was necessary to introduce at an early period of the work, a sketch of Fossil Zoology, it was equally important with respect to Fossil Botany, for plants and animals were coeval. This may to some appear like cavilling; but we have been too long students of Nature not to feel the paramount importance of good arrangements, and the excessive inconvenience of want of method; and we should be sorry to see so popular a work as that of Mr. Ansted promises to become, impaired in usefulness by inattention to such points.

We must not dismiss the Part before us without a word of praise to the printer and wood-engraver, who have each combined to render Mr. Ansted's work worthy of a place by the side of Yarrell's "Fishes." Nor should we omit a specimen of the Author's mode of treating his subject. For this purpose we select the following passage:—"I may safely conclude these introductory chapters by assuring the reader that, with regard to the various discoveries of Palæontology, they all speak the same language, and all support the same argument; namely, that, in the order of succession of those species of animals or vegetables which have preceded man upon the earth, as well as in the composition of the various strata in which they are found entombed, there may be traced, throughout, an unity of principle, acting by an infinite variety of means: and one system, perfectly symmetrical and beautiful, and adapted to every emergency, has been invariably pursued from the first creation of organised beings till now. From that far distant period when the inhabitants of the earth consisted only of the coral animalcule and the mollusc, throughout the gradual introduction of animals of higher organisation, until the day when man was created, and endowed with an intellect capable of comprehending and appreciating the infinite wisdom displayed in the great plan of creation, that plan has been the same; gradually unfolding itself until fully developed in all its extent and *perfection*."

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

QUISQUALIS SINENSIS. Chinese Quisqualis. (*Stove Climber*). Combretaceæ. Decandria Monogynia.—This plant was exhibited before the Horticultural Society in July, 1841, by Messrs. Lucombe, Pince, and Co., of Exeter; who stated that it is a more compact grower than the old Q. indica, and therefore more desirable for cultivation in pots. It manifestly differs in its smoother leaves and branches, and in the larger size of its flowers, which are, moreover, of a much deeper Rose-colour. Upon comparing it with wild specimens of the genus, it appears to be identical with the plant that is found about Canton, and which is probably the Q. indica of Loureiro. We presume it to be of the same nature as the true Quisqualis indica. That plant is a stove climber, requiring to be potted in sandy loam and peat, mixed with a few pieces of potsherds. In summer an ample supply of water should be given to its roots, and it should be syringed over head once or twice a day, as the weather permits, taking care always to have the plant dry before night; and the house, when air is given, shut up early in the afternoon, to retain as much sun heat as possible. During the growing season the temperature should average 80° by day, and 65° by night; but in winter it should never rise above 60° with fire heat. The plant may be propagated by cuttings under ordinary treatment.—*Botanical Register.*

BOLBOPHYLLUM MACRANTHUM.—Large-flowered Bolbophyllum.—(*Stove Epiphyte.*)—Orchidaceæ.—Gynandria Monandria.—This singular plant was imported by Messrs. Loddiges from Sincapore, and is closely allied to both B. leopardinum and affine. From each it differs in its much more fleshy and larger flowers, whose stalk is considerably longer than the petiole. The flowers appear in March, and expand so flat that they seem as if they had been pressed between paper. In the centre they are a pale lemon colour, but towards the tips they are much mottled with dark chocolate-coloured spots. Like the rest of the genus, it succeeds best when tied to a block of wood, and suspended to a rafter in a moist stove. If the wood is charred enough to burn off the bark, the block will be found to answer the purpose much better, and all insects that harbour about it will be destroyed. In summer the plant should receive water twice a-day at least, and the temperature should be kept about 80° by day, and 68° at night. In winter for a few weeks very little water will be required, only as much as to keep the pseudo bulbs from shrivelling. The temperature then should never be raised above 50° or 55° with fire-heat.—*Botanical Register.*

Miscellaneous.

Botanical News.—We learn with great pleasure that Mr. Harvey has been appointed Curator of the Herbarium of Trinity College, Dublin; and that he is about to make public the valuable Californian and Mexican plants of the late Dr. Coulter, which are preserved there. Dr. George James Allman has been elected Professor of Botany in the same College. We are also able to state that Government has given the sum of one thousand pounds towards defraying the expenses of publishing the Botanical collections made by Dr. Joseph Hooker in the late Antarctic voyage, and that the work will soon appear in quarto. The drawings which we have seen are really beautiful.

Artificial Fertilisation.—The attention of every friend of Horticultural science ought to be directed to a very interesting fact, which I have recently had an opportunity of observing in the course of a Horticultural tour in Belgium. In the climate of Paris, it is known that only a small number of species and varieties of the Camellia perfect their seeds. Those which commonly do so are the C. carnea, and a few species with semi-double flowers. I have thought, with other Horticulturists, that the difficulty in obtaining ripe fruit from the Camellia was attributable to the low temperature of the climate of Paris; and I was, moreover, inclined to entertain this opinion, from observing that the greater part of new varieties were from seeds ripened in Italy and sown in France. I was then very much astonished at seeing in Belgium all kinds of Camellias, almost of all ages, some only three years from the graft, bending under the weight of fruit with which they were loaded, as a Paradise Apple-tree is loaded with Apples in a favourable season. I formed the idea that this was to be attributed to artificial fertilisation; and in this I was confirmed by the following details, with which I have been favoured through the kindness of M. Haquin, a distinguished Horticulturist, at Liége. During three years in which M. Haquin has practised artificial fertilisation, he has only collected seeds of single-flowered Camellias, and preferred sowing but a few of the best seed. In the first season, out of 212 seeds, 146 grew; and, in the second, 188 plants were obtained from 294 seeds. In the present season the number of fruits on the following varieties is as under:—

Camellia carnea	.	.	3 Plants	96	Fruits
,, Donkelaeril	.	.	2 ,,	14	,,
,, King	.	.	1 ,,	3	,,
,, Press's eclipse	.	.	1 ,,	4	,,
,, Lady Henrietta	.	.	1 ,,	1	,,
,, marmorata	.	.	1 ,,	9	,,
,, punctata	.	.	1 ,,	1	,,
,, Campbellii	.	.	1 ,,	2	,,
,, Waratah	.	.	1 ,,	11	,,
,, Civiana	.	.	1 ,,	1	,,
,, variegata striata	.	.	1 ,,	6	,,
,, Loddiges' conspicua	.	.	1 ,,	2	,,
,, picturata	.	.	1 ,,	1	,,
,, nobilissima	.	.	1 ,,	3	,,
,, Weimari	.	.	2 ,,	10	,,
			19	168	

The fruit of the Camellia generally contains 7 or 8 seeds, and occasionally as many as 10. M. Haquin may, therefore, estimate his saving of this year at not less than 672 seeds, reckoning at the rate of 4 seeds in each fruit; this result promises for the ensuing year an important addition to a collection already rich in young plants. It is certain that the greater part of these Camellias would not have fruited, if their blossoms had not been artificially fertilized. The mode by which M. Haquin has effected hybridization is truly interesting. Many Azaleas have been fertilized with pollen kept for 6 weeks; that of Camellias has been employed successfully after having been kept 65 days. Fertile seeds of Lilies have been obtained from the application of pollen which had been saved 48 days. During the last flowering season of Camellias, M. Haquin collected pollen with which he intends hybridizing in the ensuing year. The following are some details of his procedure. The stamens are taken out just before their anthers begin to open; they are immediately wrapt in sized paper, and laid in a warm place for 24 hours, by which time the pollen separates from the stamens. It is then collected and inclosed in thin sheet-lead, and kept in a cool, dry place. I think the preservation would be rendered more perfect by placing the pollen between two concave glasses, as is done with vaccine matter. No limits can be assigned to the time during which pollen will retain its fertilizing power, provided the minute globules of which its masses are composed are not crushed by too great pressure. If there be a limit, it will be for experiment to ascertain. I believe the preservation of pollen between glasses is worthy of trial. The subject of the above statements is not new, for artificial fertilization has been long since practised on a large scale. But it is so powerful an agent in the hands of the horticulturist, that nothing which tends to render it more common can be considered unimportant.—*Rogonnet Godefroy*, in the *Revue Horticole, for Sept.* 11, 1843.‖

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

No opportunity should now be lost to pot all plants that require shifting. Plants that have been growing for some weeks, particularly young ones, will now require to be stopped, more or less, in order to make them bushy. Never make use of a stick to give form to a plant that can be managed by pruning or stopping. Many plants will require to be slightly shaded in the middle of the day, but this should be removed early. Use the syringe every day the sun is out strong; be cautious in watering newly potted plants, and guard against insects.

Conservatory.—Roses and all scented flowers that retain their sweetness after drying, should be gathered as they begin to fade, and carefully dried at this early season; those, if placed here and there through the rooms, will be better liked by many persons than fresh flowers. Orange trees require particular attention when they are making their young wood; stop luxuriant shoots at the fourth or fifth joint; no one part of the head should be allowed to grow stronger than the rest; young trees may require some of their stronger branches to be tied down for a time, which will strengthen the others. Forced Rhododendrons and Azaleas are the best from which to obtain hybrids; this is a good season for crossing them. Climbers for this house should soon be planted, if additions are to be made to them this season, and see that the young growths of the old ones do not get entangled for want of training.

Greenhouse.—Plants in this house will require all the air that can be given them, and they will be liable to get very dry on that account; water them late in the afternoon, and damp the paths and all empty spaces freely; give them besides a gentle syringing three or four times a week, when the weather is fine. These plants require constant attention now to stopping and regulating their growth.

Forcing-pits.—As these pits are the last places for spring propagation, and as this work does not admit of large portions of air being given, they must be regularly shaded in hot dry weather—thin hunting or calico should be used for this purpose, mats darken too much. Remove Roses and other plants as soon as their first blooms are ready to open. To get handsome plants of the different hardy shrubs for future forcing, cut down some of them now in the shrubberies; the strong shoots from the stools may be layered in summer, and with a little nursing they will soon make far better plants than older ones.—*D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Out-door Department.

Newly planted trees and shrubs will require strict attention in regard to water, as they already indicate the want of it. It is better to give them a thorough soaking at once, than to give them a little water, frequently repeated; and after the surface of the ground is dry, fork or hoe it over, and then mulch with short grass, to prevent the evaporation of moisture. The same remarks apply to newly planted annuals, which must be shaded as well as watered. Turf, which has been recently laid down, requires strict attention. It will be a good plan, after giving it a good soaking of water, to dress it over with old tan, or leaf-mould, and then shade it by covering the ground with pea-sticks, or any refuse branches that may be laying about. Get in a successional crop of Sweet Peas, and any other Annuals that were sown early in the year. Sow Ten-week Stocks for transplanting. The finer kinds of Gladioluses which have been brought forward in pots, may now be planted out, giving them a deep, rich, and well-drained soil; but it will be as well to protect them by an inverted pot at night, until all danger of frost is over. Attend to covering half-hardy shrubs and trees, or, as the sap is moving, one night's sharp frost, which we are not unlikely to have, will undo all that you have done in the way of acclimatising for years.

Pits and Frames.—Proceed with the potting off all plants for bedding out; those which have become established and hardened may be removed into temporary pits, and covered with mats. Some neat and very convenient permanent structures for protecting plants in small pots, may be seen in the nursery of Mr. Rivers. They consist of pits three feet wide, formed of large paving tiles, placed on edge and cemented together, they may be covered either with shutters, mats, or a large tarpauling to cover five or six ranges. Where flower-gardening is extensively practised, 500 or 600 feet of pits of this kind would be invaluable, and would not be very expensive.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Auriculas.—As the consummation of the Florist's hopes—a good and general bloom of this favourite flower—is now rapidly approaching, his constant attention to their various wants, such as shading from the mid day sun, watering, &c. &c., is imperative. As the trusses rise, the plant will sometimes produce two, should there be more hearts than one. In this case it is best to remove the weaker, and with a sharp-pointed pair of small scissors thin out mis-shapen buds from the centre of the truss, leave it so that the best may have room to expand freely and equally. It is highly important just now that the pots should never be allowed to get too dry, though indiscriminate watering must be avoided. *Tulips.*—The late fine weather has brought these flowers on fast, and they are looking unusually well throughout the country; some growers, however, complain of many of their bulbs missing bloom having only put up a single leaf. The beds must be kept free from weeds, and the surface loose. *Polyanthuses.*—These usually flower at the same time as the Auricula, or perhaps rather earlier. Plants on the border must have their trusses shaded with small boards, or other covers, as some of the varieties are apt to have the lace or edging of the flowers "blanched" by too much sun. Plants in flower may be taken up with a ball of soil, and potted, with perfect safety, for exhibition. Snails are very apt to mount the stems, and eat out the thrums, leaving their slimy track as a proof of their delinquency. *Ranunculuses.*—Seedlings may now have plenty of air and morning sun, but never let them get thoroughly "drought-ed." Frames covered with calico coated with some transparent composition, will doubtless answer admirably for their protection. *Pinks.*—The late dry weather has been anything but congenial to spring formed beds, and unless shaded, watered, and well attended to, they will suffer materially. *Carnations.*—Potting out should now proceed rapidly. Well drain the pots, putting a little moss over the broken tiles, cinders, pot, or whatever may be used for this purpose, that the soil may not run in and prevent the free egress of water; fill with compost, and, according to the size of your pots, place one or two layers, giving them a gentle watering, to settle the soil; after which, place them in the shade for a few days.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—Plants swelling their fruit will require to be frequently looked over this fine weather. Give water to those re-

quiring it; but do not give any till they require so much as to wet the soil thoroughly. You will by this course avoid the evil of having the soil soddened; a thing certain to occur to some, if water is given whenever the surface appears dry without examining the state of the soil below; the plants being plunged, the soil in the pots is often sufficiently moist when the surface appears dry. Liquid manure will greatly benefit the plants in fruit, and those for autumn and winter-fruiting, as soon as they are known to be rooting freely.

Vinery.—The utmost attention must be paid to timely thinning the bunches of Grapes, stopping laterals, and tying in the leading shoots, also the spurs or bearing shoots. Give air early on clear mornings, that the leaves of the Vines may be dry before the sun comes full upon the houses. The Tokay and Cannon Hall Vines require shading in very bright sunshine, as the foliage of the former is liable to be scorched, and the fruit of the latter to acquire a scalded appearance: thin bunting would be very suitable for the purpose.

Peach House.—Give plenty of water to trees swelling their fruit. I find that the syringe keeps the trees perfectly clean of aphides; and tobacco water banishes from the trees or destroys the thrips. The late house should now be kept at 50° by night, and have air admitted from 9 in the morning till 5 in the afternoon during mild weather.

Fig-House.—Figs lately commenced growing should have plenty of water. Continue to stop the lateral shoots of trees more advanced, above the second or third leaf. Give plenty of air when the atmosphere is clear and warm, to keep the large and numerous leaves of the Fig in a healthy state.

Melons.—If the Persian Melons, planted out early, have been shaded from the sun, it will be proper to discontinue it by degrees, till dispensed with altogether. Avoid wetting the foliage after the shoots begin to grow freely, and endeavour to induce a firmness of texture in all parts of the plants. When the sun is bright and much air admitted, keep water in the vapour troughs and sprinkle the soil lightly; but in dull weather keep a drier atmosphere.—*G. F.* [In last week's Calendar in Peach-trees, read "stoning" instead of "showing."]

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Strawberries.—In cold exposed situations, plantations made now from plants, pricked out thinly last autumn in a sheltered situation, will succeed better if transplanted with balls, than if the plantation had been made in the autumn. The ground should previously be well trenched and manured, as no spade ought in future to be inserted amongst them, until it is necessary to dig them down. A plantation will stand, and produce plentifully many years, if, after bearing every season, the beds are thinned out, so that those left will have their leaves fully exposed to sun and air. Unless for new kinds, there is no method of making fresh plantations comparable to that of turning out those forced in pots. By this method I prolong the Strawberry season until frosty nights set in, and the same plants produce plentifully the following June.

Turnips and Radishes.—Sow on a warm border. If sown in alternate rows, the Radishes will be pulled out of the way of the Turnips. To have the latter juicy and sweet, sow every fortnight until August. The Snowball is an excellent early variety. Follow with the white Dutch, which is the most general favourite with the *artistes* of the kitchen. *Beans and Peas.*—Earth up and stake if necessary forward crops, and keep sowing successions of the Windsor Beans, and the Marrows and other large Peas. The Victoria Marrow is an excellent Pea, considerably earlier but not so good a bearer as Knight's tall or dwarf Marrow. The new sorts will be sufficiently tested this season. *Kidney Beans.*—Sow a few of the early Negro or Fulmer's Forcing on a warm border; also a number of pots to be placed on a slight hot-bed, to be gradually hardened and turned out when all danger from frost is over. The frames and glasses used for forwarding Cauliflowers, &c., will now be useful for Beans, Tomatoes, Capsicums, Cucumbers, &c. *Routine.*—Stir the soil among all advancing crops, earth up Cabbages, water Cauliflowers. Keep the Dutch hoe in motion during this fine weather, which will not only prove hostile to all springing weeds, but prevent your ground getting dry and cracked from rapid evaporation.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—Should now be gone through, to fix upon and mark what Oak-trees, or others required for the bark, should be cut down before the peeling season commences. The same should be done with resinous trees; now is the best time to fell such trees, when the sap begins to flow.

Coppice.—The cutting of poles, cuttrods, rods for watling, or other purposes, may now be proceeded with. This is the best season for such work where a vigorous succession crop is required. Birch should be left until it is further advanced, in order to prevent injury from bleeding.

Young Plantations.—All planting for this season, where not previously completed, should be finished as soon as possible. The planting of evergreens is generally recommended to be done in April or May, but I would prefer October and November. All works formerly recommended should be completed as soon as convenient, such as thinning, weeding, hoeing, and fastening newly-planted trees. Training, shortening, and removing some of the strongest and too numerous side branches, may be continued through this and the next month.

Hedge-rows.—Young trees, in old hedges, should be relieved from the encroachment of Thorns, Briars, Hazels, &c.; in order to encourage side branches, they should be trained to one upright leader. Remove the strongest side branches, and shorten some of the moderate-sized ones, to prevent them from getting too large previous to their final removal.

Nursery Work.—Now, that the weather seems settled, this should be a busy time in this department; sow seeds, nuts, kernels, &c.; plant cut seedlings and other small plants, but take great care not to allow the small tender fibres to get dry after the plants are taken up; it would be a safe way to have a bucket with a puddle made of cow-dung, mixed with a little loam or clay, to put their roots into before planting, or while the operation is going on.—*W. B.*

VII.—COTTAGER'S CALENDAR.

This spring having been cold and wet, everything is later than usual. In the meantime, during these sunny days, prepare for the main crops of Carrots and Parsnips, so as to get them in when the ground is dry. Both of these like a deep rich soil, and if it is of a light nature, it is the more suitable for them long tapering roots. They should follow a crop for which the ground was previously well manured; for if manure is applied in spring the roots will be forked and wormy wherever they come in contact with it. Parsnips require a greater distance between the rows than Carrots; they should be sown in drills from 15 to 18 inches apart, and about an inch deep. The seeds being smooth do not require to be mixed with soil like Carrots; but in every other way they may be treated alike. Drilling crops, where it can be done, is far more convenient than sowing broadcast, as the intermediate spaces can be easily cleaned and stirred up, which is of great benefit to the plants. A sowing of Beans may now be made. If the first sown Peas are not already staked, it should be done without delay; if they are not sufficiently earthed up, draw a little more to them before staking them. Sow some to come in in succession, four feet apart, to make room for Spinach to grow between them. It is time for getting in Potatoes, planting them about 2 feet apart. A sowing of Curled Parsley should also be made without delay; it delights in a good fresh soil. A small patch of Radishes should be sown, for succession, about once in three weeks. Lettuces, Celery, and Cauliflower, may be sown in a warm border, the latter to succeed those that should now be planted out. *Flowers.*—Do not uncover anything that is tender for a short time yet. Continue to dress the borders. *Fruit.*—Get Strawberry-beds (if any) weeded, before the plants have grown much, and keep down weeds wherever they appear.—*M'H.*

State of the Weather at Chiswick during the last 18 years, for the ensuing Week ending April 13, 1844.

2d Slight frost early A.M.; very fine; clear and mild
3d Fine; very dry air; clear and fine at night
4th Very fine throughout
Mean temperature of the week, 5.2 deg. above the average.

Notices to Correspondents.

BOOKS.—*A Bachelor.*—Bevan on the Honey Bee.—*Rusticus.*—Mangles's Floral Calendar; apply to the booksellers.

CHARCOAL.—*Beginner.*—Prepare it from the softest wood you can get. Possibly your Pines are over-watered, without being enough exposed to light.

CONSERVATORY.—*T. J.*—A span-roof by all means, and if possible, running north and south. Glaze with the largest panes of sheet glass, if you do not mind the expense, and heat it by hot-water pipes, cast with evaporating pans. Brick water-gutters will not answer for a conservatory in winter. Have a tank inside in which you can keep water of the same temperature as the air of the house. Such a tank may be fed with the rain that falls on the roof.

CARNATIONS.—*Lambo.*—Those, Picotees, and Pinks will grow in almost any kind of soil; but they do best in a light rich mould, consisting of old turf, well-decayed dung, leaf-mould, and sand. For their management, see to-day's Calendar.‡

CROCUSES.—*Delta.*—Both these and Snowdrops like a warm, dry, light soil, in which they will thrive for many years without requiring removal. Both are, however, better for being taken up occasionally, because in that way their roots are exposed to fresh soil, and are not obliged to search through exhausted earth for their necessary food. They are fond of cow-dung as a manure; it may be applied just after Christmas. Transplant all Evergreens in November if you can, and when the weather is wet. The worst of all times is the spring, when the easterly winds prevail.

EVERGREEN BEECHES.—*Paris.*—It is true that the Evergreen Beeches have been lately received, in a living state, by Sir W. Hooker, at Kew. There has not, however, been as yet any multiplication of these rare plants, which are seedlings. It is hardly to be expected that they will be hardy in those parts of Europe where the cold is intense in winter.

FOUNTAINS.—*M. C. M.*—I should recommend the supply-pipe to be six inches diameter in the bore, where the ground falls rapidly; four inches in the level part, and three inches in the length, which ascends to the fountain. The six-inch pipes should be of half-inch metal, and the others three-eighths of an inch; the lengths may be united by flange joints, but turned and bored joints are more accurate and lasting. The nozzle should be made of brass, trumpet-shaped, and the orifice one inch in diameter. The supply-pipe must be kneed from the level to the upright position, with a flange to unite to that on the bottom of the nozzle. It will be found advisable to try the effect by wooden nozzles, of various sized orifices, before the permanent one is made. The small pipes which are to supply the house and offices should, at their junction with the main, be very stout, and about half an inch bore. Considering the head of water, if these rules are followed, the jet may be expected to rise from 60 to 70 feet, providing there is an ample supply, of which "M. C. M." says nothing. I know of no work treating of fountains, which would afford information applicable to the case in question.—*Joseph Paxton.*—*T. J. M. A. P.*—Next week if possible.

FRUIT-TREES.—*V. B. K. Z.*—On the south aspect, inside, the following trees will be proper:—Peaches, Royal George, Bellegarde, Noblesse, Malta, and Berrington; the Elruge, and 2 Violette Hative Nectarines; 2 Moorpark Apricots. For the south aspect, outside:—Cherries, 2 May Duke; 1 Knight's Early Black; Plums, 1 Royale Hative; 2 Green Gage; 1 Coe's Golden Drop; Glout Morceau; and Beurré Rance Pears; and the Mulberry you wish to have. For east and west aspects:—The Royal, Orange, Roman, and Moorpark Apricots; Plums, 1 Kirke's, 2 Purple Gage; Pears, 4 Winter Nelis, 4 Bacon's Incomparable, 2 Marie-Louise, 2 Passe Colmar, 2 Glout Morceau, 1 Thompson's, 2 Easter Beurré, 2 Knight's Monarch; Cherries, 2 Elton, 2 Florence.‖

GRAFTING.—*J. Jeffrey.*—One year old wood of the Purple Beech will not take with any certainty. Two years' old wood will never fail; we have not tried three years' old wood.

INSECTS.—*J. Took.*—The Cucumber-leaf was so crushed, that it was impossible to examine it. I should feel obliged by having a fresh leaf, with some of the little beetles upon it, and as many as you can conveniently send in a pill box. Say, also, at what period of the day, or night, they are eating the leaf, and if there be any season when they are more abundant than at present. *R.*—*A Beginner.*—Old Cabbage leaves laid in your Mushroom-beds will attract the woodlice, when they may be collected and killed every morning. As they harbour in the decaying wood of the frames which rest upon the soil, boiling water may be poured round that part inside and out; but one of the best remedies is to keep one or two *toads*, not frogs, in each frame. *R.*—*A. F.*—Your enemies are a species of woodlouse, called Oniscus murarius; kill them by the modes above recommended. *R.*—*Monmouth.*—Fumigating with tobacco will, in all probability, destroy the red insects; but we must beg of our correspondents to transmit specimens, without which it is impossible to give satisfactory answers. *R.*—*J. C. K.*—The foliage of your Fuchsias is undoubtedly eaten by some insects much larger than the one you placed in the quill; which, however, had escaped for want of being stopped with a *cork*. If you will examine your plants by night, I expect you will detect the culprits feeding. *R.*

LAWNS.—*Penthesilea.*—If you water your lawn well with gas-water and water, it will kill the Moss, and improve the Grass. Do not be alarmed if you should seem to have killed the Grass also, for that will recover. ‡

MANURES.—*H. J. D.*—For the price of superphosphate of lime see our advertising columns. Apply it to Pelargoniums now, as a top-dressing, about a wine glassful to a plant, and just scratch it into the soil.—*Mercator.*—Superphosphate is used in kitchen-gardens at the rate of 3 or 4 cwt. an acre. Oranges love a rich free soil—even such a manure as charcoal soaked in blood. They will, however, never thrive unless they are kept warm at their roots, and have plenty of room to grow in. Peat, loam and sand, equal parts, form a soil suitable to the Gladiolus.—*Rhodon.*—Three or four cwt. per acre of Potter's guano will probably be sufficient for your Roses: we do not, however, know what the maximum quantity is that may be advantageously used. Much, moreover, must depend on the condition of your land.—*M. A. B.*—Use Potter's guano as a top-dressing, and prick it in. As far as our experience goes, it suits everything; but we have not seen it tried on Coniferous plants. A good companion for a Petunia in a vase would be a Purple Salpiglottis; or, if you cannot get it, one of the taller purple Verbenas.—*H. C.*—Mix lime with your guano, and if you perceive strong ammoniacal fumes, it is probably good. There is no certainty about it, however, without careful analysis. The African guano is said to be good; but if it is very wet, you will have to buy water as well as guano; and as you have probably enough of that at home, it must of course be taken into consideration. Take a pound of the wet guano, put it in the sun to dry, and weigh it afterwards. The difference will be the water.—*J. A.*—It is worth trying whether water from gas-works would improve refuse hair. We have no experience with it.—*Guidenet.*—The superphosphate of lime, or Potter's guano, rather than the Peruvian. Apply them as a top-dressing; just fork them in, and leave the rest to the weather, unless it should remain very dry, in which case it will be necessary to water the border. Apply at the rate of 4 cwt. per acre.

NAMES OF FRUITS.—*J. Waldron.*—Dumelow's Seedling. ‖

OAKS.—*R. F.* may prune Oaks and Beeches now. Mr. Glendinning, Turnham Green.

ORANGES.—*J. A.*—Your Oranges drop their blossoms because their roots are too cold.

PEARS.—*An Original Subscriber.*—The Winter Crassane differs from the old Crassane in having the eye in a still larger cavity; but if you plant both side by side you will soon discover a most important distinction, for the Winter Crassane will bear most abundantly as a Standard, whereas the other will not. You will find a figure and description of the Louis Bonne of Jersey, at p. 860 of last year's *Chronicle*. Thompson's Pear resembles in appearance the Passe Colmar; but the leaves differ in being somewhat downy, and the fruit is more buttery. You have probably been too late in heading down your Quince-stocks. If this is not done early they are very apt to canker at the graft in the manner you describe. They ought to be headed down in January at the latest. You must not cut those you budded quite close to the bud at present, nor till they are fairly in leaf.‖

PICKLING WOOD.—*B.*—Apply to John Bethell, Esq., 78, King William-street, City, for Creasote.

PINE SEEDS.—*K. O.*—Sow them now in sandy loam, in a cool Cucumber frame. Remove them to the open air as soon as up, if the frosts are over. Put them as soon as they form their second leaves, and plant them out as soon as they are six inches high. Do not crowd them; and never let their roots become spiral.

PLUMS.—*A. H.*—The Myrobalan Plum is Prunus cerasifera—quite a distinct species. Thanks for the information, which we have used elsewhere.

RABBITS.—*S. S.*—We are not acquainted with the mode of destroying Rabbits by smearing Cabbage-leaves with poison. You may surely trap or snare them, if you cannot shoot them.‡

SEEDS.—*R. C. R.*—Of your seeds the following are worthy of growing:—Lagerstroemia Regina, Eranthemum nervosum, and Convolvulus Lucteus.‡

SHRUBS.—*Sarah.*—The following ornamental evergreen and deciduous plants may be recommended for planting in a shady situation in London: Common and variegated Holly, Aucuba Japonica, Laurustinus, Berberis aquifolium, Viburnum opulus, Cytisus Laburnum, Common and Persian Lilac, Ribes sanguineum, Cornus sanguinea, Hypericum androsæmum, H. calycinum, and Symphoria racemosa.‡

SLUGS.—*An Amateur.*—Lime-water applied night and morning, when the slugs are feeding, will soon rid you of such vermin. Or gas water is much better, provided you can apply it without its touching your plants.

THE ROSE-GARDEN.—*J. L.*—Patience is a virtue, and we must beg of you to exercise it. It is not our intention to resume the articles under this name for a few weeks, as all that relates to the actual season is already printed. You may expect their re-appearance about the beginning of May.

THORNFIELD PINES.—*Three Gardeners.*—Obliged by your information; but you must give us your names if we are to use it.

MISCELLANEOUS.—*Egg.*—We know of no means of preserving the colour of birds'-eggs except keeping them in the dark.—*W. M.*—Helonias asphodeloides thrives perfectly in a peat border among American plants, where it is shaded, but not overshadowed. It then flowers every year.—*Jason.*—It would be very unfair of us to answer your question. There are doubtless many professional men who are excellent landscape gardeners, and it would be invidious publicly to name one in preference to another.—*Anon.*—We have no idea to what you allude. Many plants have an acrid juice, and will raise blisters; as for example the Crowfoots and Clematis flammula.—*Anglus.*—Leaf-mould that is well decayed may be used instead of Bog-earth for American Plants.‡—*G. F. H.*—By application to the Secretary in Regent's Park. Verbenas like a light rich soil: it is too early to plant them yet.‡—*Rhodon.*—We are not acquainted with the Rhododendron "Gloire d'Haarlem." We have had no experience with Potter's guano for American plants.‡—*Col.*—The meetings of the Horticultural Society are on the first and third Tuesdays of the month, with certain exceptions, which can be learnt at 21, Regent-st.—*C. R. D.*—No doubt your Gooseberry bushes have been attacked by birds.—*2s. 6d.* will be given for No. 33 of 1842.

SEEDLING FLORISTS' FLOWERS.

CAMELLIA.—*W. B. T.*—The variety of which you have sent a specimen is not known: its principal merits consist in its colour and the texture of the outside petals; the centre is very bad, being partially filled with small narrow petals. *

CINERARIAS.—*W. M.*—Queen of the Fairies is like so many varieties we have with delicate-coloured tips to the petals, that it is impossible to distinguish it from many others. Model forms a more decided variety, being a mixture of purple and azure. Single flowers are not sufficient to form an opinion upon.* —*C. L. N.*—Seedling No. 1, a bright blue. The flowers of this variety are rather small; but they are very abundant, and bright and beautiful in colour. No. 2, pure white centre, with the termination of the petals of a delicate azure blue. This is also an abundant bloomer, with well-formed flowers, lively in appearance, and forms a distinct and desirable variety.*

PANSY.—*T. O. G.*—Everton is a fine, large, well formed seedling, with well-proportioned petals of a velvety texture; upper petals of a very deep purple, with a perfect broad belting of the same colour round the side and bottom petals; eye dark, ground colour yellow: it wants a little more decision where the belting joins the ground-colour.*

RHODODENDRON.—*C. L. N.*—The seedling hybrid Rhododendron is a very compact and handsome variety, the blotches of white with the deep rose colour of the outside of the flowers, contrasted with the delicate and spotted inside, give great richness to its general appearance: the fringed edge to the corolla is a defect. *

SCARLET GERANIUM.—*W. M.*—Fireball is a bright colour, but not surpassing in this respect many others; and the habit of the plant we are ignorant of.*

*** As usual, many communications have been received too late.

TO THE FARMERS' CLUBS AND AGRICULTURAL SOCIETIES, in Gloucestershire and the adjoining Counties.—It having been suggested to me, by Mr. Hyett, of Painswick, that it would be desirable to place within the reach of the farmers, upon reasonable terms, the means of obtaining the analysis of the various manures of commerce now coming into use, so as to estimate their commercial and agricultural value, I have determined to offer my services to the several Farmers' Clubs within my neighbourhood, upon the following terms, viz.: that upon being appointed Chemist to any Club, with an annual fee of 5*l.* 5*s.*, I will analyse for their members, at the undermentioned reduced charges, viz.:—

1. *Manures*.—Testing saline manures, such as guano, the nitrates of soda or potash, bone-dust, rape-dust, &c., for adulterations, for each sample, 3*s.* Examining, with a view to its commercial and agricultural value, any of these manures, so as to detect the quantities of impurity, or estimating the amount of phosphates, or animal matter, contained in any sample of bones, or of organic or of inorganic matter in any mixed manures, 6*s.*

2. *Soils*.—For estimating in a soil the amount of soluble saline matter, or of lime, clay, silex, phosphates, gypsum, organic matter (humus), &c., or the power of retention of water by a soil or subsoil, as indicating the necessity of draining for the estimation of one ingredient, 5*s.*, and 2*s.* 6*d.* for each additional one.

3. *Earths*.—Examining limestones, marls, &c., to ascertain the proportion of lime, and presence of magnesia, alumina, or silex, 5*s.*; ascertaining the proportions also of either of the latter, or any other ingredient, 2*s.* 6*d.* extra for each.

4. *Products of Vegetation*.—Examining the ashes of a plant, to determine the proportion of one ingredient, 5*s*; the proportion of every other, 2*s.* 6*d.* additional for each; and for examining, to determine the quantity of water, starch, sugar, gluten, vegetable albumen, or woody fibre in Turnips, Potatoes, Mangold Wurzel, Wheat, &c., 5*s.* for the first, and 2*s.* 6*d.* for each additional ingredient; and for determining the quantity of oil or fat, and of other proximate principles, requiring expensive re agents, in any agricultural crop, 5*s.* each.

5. *Dairy Produce*.—Estimating the amount of casein, fat, sugar, or salts, contained in milk or cheese, with a view to comparing the produce of two or more breeds of cows, or of different modes of feeding, for each ingredient, 5*s.*

6. A Lecture on any Agricultural subject, 2*l*, to 5*l.*

7. For chemical advice generally, on Agricultural subjects, the charge must be regulated by circumstances.

8. Water or liquid manure examined, with respect to its fitness for irrigation.

I am, gentlemen,
Yours, most obediently,
Painswick, March 26. A. GYDE.

TO AGRICULTURISTS, MINING PROPRIETORS, MANUFACTURERS, and OTHERS.

ROYAL POLYTECHNIC INSTITUTION.—The department of ANALYTICAL CHEMISTRY and Chemistry applied to the Arts, Manufactures, and Agriculture, now offers considerable advantages to parties engaged in the above-mentioned pursuits, both as to the moderate scale of charges, and the punctuality and accuracy with which all Analyses are conducted. The Chemists may be consulted at the Institution daily, after 11 o'clock, or in the country, if required. Simple Assays, one guinea each. Analyses, from one guinea upwards. Where business is regularly sent to the Institution the charges are reduced. R. J. LONGBOTTOM, Secretary.

The Agricultural Gazette.

SATURDAY, APRIL 6, 1841.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, April 10, Agricultural Society of England.
Thursday, April 11, Agricultural Imp. Soc. of Ireland.

Wednesday, April 17, Agricultural Society of England.
Thursday, April 18, Agricultural Imp. Soc. of Ireland.

FARMERS' CLUBS.—April 8 { West Hereford. Wickham Market.

During the years 1842 and 1843, upwards of 400 experiments with manures, of which we have the manuscript report, were made by Mr. Lawes, whose name will be recognised as that of an intelligent writer in the *Agricultural Gazette*. We mention this to show that the opinion of this gentleman on the general subject of experimental farming is well worthy of our attention. It will be seen from the following remarks by him, that his extensive experience in this line fully proves the amount of error to which experiments are liable, from the influence of other causes than those specially employed by the experimenter. The way to remedy this is—either as already pointed out on many occasions, and as Professor Henslow has put in practice—by collating the results obtained from the action of the same cause, by different observers, under a great variety of circumstances, or by —what is very similar– increasing. not the number, but the extent, of the experiments. Mr. Lawes writes as follows :—

"I venture to offer some remarks upon this subject, having been engaged during the last few years in performing a variety of experiments, and having wasted a great deal of time and money, from ignorance of the precautions necessary to obtain an accurate result. A person wishing to try a variety of experiments is naturally anxious to perform them upon as small a space of land as possible. I have divided whole fields into spaces of the fortieth of an acre; and although the greatest possible care was taken to ensure accuracy, the results were unsatisfactory. I have since ascertained, by careful observation, that equal spaces of land measuring the fortieth of an acre, unmanured, or manured with the same substance, yield weights which vary in the proportion of 1 to 1¾. The greatest variation occurs in Clover and Grass; and I am inclined to think that half an acre is the smallest quantity of land that ought to be used for one experiment upon these crops. The manures should be reduced to a fine powder, and sown by hand when the Grass is beginning to grow; I prefer the month of April, a rainy day being selected for the purpose. The Grass should all be cut the same day, and treated in every respect alike, until it is fit to carry. Each experiment should be made into a separate stack, and thatched; the weights should be taken about two months after the Hay is carried.

"Experiments upon Wheat, Barley, and Oats, may be performed upon a quarter of an acre. I prefer the beginning of May for top-dressing with soluble salts, such as sulphate of ammonia, guano, &c. In harvesting the experimental portions, they may either be made into stacks in the field, or they may be threshed out at once in the barns. Experiments upon Turnips may be conducted upon much smaller spaces of ground, provided a space of not less than 27 inches be left between the rows; the fiftieth of an acre will give a very fair result, particularly if the Turnips are sown upon the ridges. A space of 129 yards long, by 27 inches, is about one-fiftieth of an acre. If a portion of ground of this size is used, a drill should be employed to sow the Turnip-seed, and the manure should be strewed by hand down the marks made by the drill, a light roller being passed over them to cover the manure. The seed should be sown very thick, to prevent injury from the fly; and to enable the Turnips to be set out at equal intervals, each row should contain an equal number of Turnips. The Turnips should be weighed about the beginning of December; all the roots, dirt, and tops, should be completely removed, and the bulb weighed. This is the only fair way of estimating the weight of a crop of Turnips, and if it were done, we should not hear so often of crops weighing 30 tons per acre."

No kind of experiments can afford more useful results than those instituted for the purpose of ascertaining the limits within which the results of other experiments can be depended upon. Mr. Lawes refers here to the effects of manures alone, and a good deal of the variety there noticeable is, it appears, owing to variety in the soil, and to other disturbing causes. There are many kinds of experiments connected with the soil, to each of which the above remarks by Mr. Lawes will apply, as they are all equally affected by the same sources of error; such are experiments with different varieties of any plant, for the purpose of determining the one of greatest productiveness. But there is another class of experiments, of great importance to the farmer, which aim at the determination of the nutritive properties of different kinds of food, or of the fattening tendencies of different breeds of sheep and cattle; and in these we can say, from experience, that the greatest care is required in drawing accurate inferences from the results arrived at.

We have no doubt that, were a sheep-farmer to divide his flock into tens, and observe them weekly, he would often find as much difference between these different lots, though fed and treated alike, as another would who had treated his lots variously, feeding one on Carrots, another on Swedes, a third on Field-beet, without hay, and a fourth, fifth, and sixth on all these, with hay. It requires a whole season at least, and a flock ten or twenty at least in number, to determine the merits of any peculiarity in the management of sheep. And while on this point, we may just mention one particular which appears to have been overlooked by experimenters on the value of different roots as food for cattle or sheep. A great source of error in all such experiments lies in the fact, that most of the different roots grown by the farmer come to perfection at different times during the year. The common Turnip should be all consumed by November, the Swede by March, while the Mangold Wurtzel and Carrot are as good, or even better, during the months of April and May as at any period while they are fit to eat. Thus, of two experiments with Swedes and Beet made on different lots of sheep, the one in December and the other in May, the former would probably result in proving the Swede to be the most nutritive food, and the latter would probably justify a preference of the Beet. We cannot tell how far to depend upon such experiments till all their details are made known.

It will soon be SEED-TIME FOR THE MANGOLD-WURZEL. This plant prefers a light soil, but will succeed on much heavier land than is suited for Turnip culture. It should be sown before the end of April. The land (a Wheat or Oat-stubble ploughed deeply in autumn), having lain exposed to the action of the weather during winter, will then harrow down to a fine tilth. It should be ploughed, not very deeply, about ten days before sowing; and, if the weather be warm and drying, the harrow and roller should follow close upon the ploughman. When, after repeated harrowings, the soil has been rendered sufficiently fine, the manure may be laid on; and in doing this, either of two ways may be adopted. It may be applied broadcast, *i. e.*, it may be emptied out of the carts in heaps at the rate of about 20 tons per acre, and spread evenly over the surface; after which, it should be immediately ploughed in, and then the land should be harrowed, rolled, and bouted up for sowing as soon as possible; or the manure may be applied in the drills, and this is generally the more economical plan. In this latter case, we suppose two ploughs to be at work; the land is first ribbed by these, a furrow being turned out, and a drill formed every 26 inches. As soon as a few drills are thus formed, the carts with manure are led up the centre of each three, and a man pulls out the load at a regular rate without stopping the horse. Supposing he has been directed to apply 20 tons per acre, he should then spread a load of 15 cwt. over about 84 yards in length. This is divided amongst the three drills to which it belongs, and spread evenly along the bottom of each by three men, who follow close behind the carts. The ploughs, by which 12 drills may by this time have been formed, three of which are then filled with manure, instead of continuing merely to bout up fresh drills, should now work round and round those already prepared; on the one side, splitting those first made in which manure has since been laid, covering it up, and leaving the land ready for the seed; and on the other, opening new furrows. There will thus never be more than 12 drills open, and in never more than six is there manure lying exposed to the air. Two ploughs, with manure-carts and men to keep them going, will get over 5 or 6 acres a-day. The land as it is thus left, should be rolled and sown as soon as possible. If it be in fine tilth, and the ploughman skilful, the drills need not be formed by a complete bout of the plough; they will be sufficiently well made by a mere ribbing of the land.

The seed should be sown as soon as possible after the drills are ready to receive it. It should be dibbled in by hand. We have not seen the machines at work which are described in some publications, for forming the holes to receive the seed; but from the statements of others we believe that they greatly facilitate the work. Before sowing, the drills should be rolled lengthways by a light roller, in order to flatten them, render the ground firmer, and hinder any chance of the dibbles being pushed in too far. This is of great consequence, as the seed is very easily buried and destroyed. To guide the dibblers in this work we have been accustomed to use a wooden roller about one foot in diameter, having upon it at intervals of one third of its circumference, strips of wood of triangular section nailed lengthways. These, as the roller passes up and down the drills, make marks across them at equi-distant intervals of about 12 inches. The seed is sown upon these marks, and thus comes up regularly over the field. The women and children who plant the seed use a short dibble, which they learn to press only half-an-inch into the land; they have a small bag of seed tied round the waist, and they hold a little of it in the left hand, from which by the action of the thumb and fingers they separate two or three berries at a time. They stand on the left side of the drill to be planted, with the right foot upon the top of it; bending, and stepping forward with the left foot, they strike a hole in one of the aforesaid marks, and on lifting out the dibble they place the two or three seeds, which they have ready between the fingers and thumb, in the hole thus prepared, and without lifting it they drag or slide the right foot along the top of the drill and cover the seed up. The covering is done wholly by the right foot, which rests above and presses the seed thus covered, while the left takes another step of 12 inches, and the hands are employed as before, first the right in forming the hole, and then the left in placing the seed, after which it is again brought forward to cover up. A great deal depends upon the proper division of the work among the feet and hands, and on each member performing its appropriate office. When once a labourer gets into the way of it, he can perform his task so rapidly that it appears as if he were running along on all fours.

The quantity of seed thus sown varies from five to seven lbs. per acre. The kind of seed to be sown should be one of three kinds—the long red, and the red and yellow globe. Last year, by weighing two or three successive rows of each kind, we ascertained that there was a produce of 31½ tons per acre of the first, and 33½ and 33⅓ of the second and third. The globe Beet is believed to be of the best quality.

Each of the berries in which the seed occurs contains three or four seeds, so that from the two or three berries which are sown at each spot in order to ensure plenty of plant, a little bush of plants springs, and whenever these get sufficiently large they must be singled out. Before doing this, however, the land should be horse-hoed. This pulls down the ribs and fills up the furrows, leaving untouched a space of only 3 inches wide up the centre of each drill, in which the plants are situated, and this is easily cleaned by the hand-hoe. Not only waste of time, but injury to the plant, is frequently committed in this operation, by the care which the hoer takes to treat the young plant gently. The proper way to do it is this :—The little 3-inch-wide ridge in which the bunches are situated should be knocked away by a push from the hoe, directed so as at the same time to knock away one third of one of the bunches; the effect of this is, to leave two or three of the centre plants of the bunch unsupported, which accordingly fall down

upon the space cleared by the hoe; another well-directed blow, a pull of the hoe as it returns, will clear away the rest of the bunch, and then, of the two or three helpless plants remaining, one may be selected, and the rest cut off. A field thus treated looks very forlorn immediately after hoeing, but the advantage of the rough treatment shows itself in a very few days by the vigorous growth of the young plants.

We shall speak more fully, when on the subject of Turnip culture, of the advantages of repeated horse-hoeings as long as the rapidly-growing leaves of the plants will permit it. At present, we leave the cultivation of the Field-Beet till its harvest time.

ON THE FERTILISERS OF COMMERCE.

To the farmer who reflects that all increase in his crops beyond the average which covers his costs of cultivation, &c., is clear profit to himself, any mode by which such increase is likely to be effected should be matter of serious consideration. Attention has lately been called to the very extraordinary returns from some of the manures of commerce; from the many which have been published I shall content myself with citing the following instances.

From nitrate of soda, applied to Wheat, the increase has frequently been great. Mr. Bubb, in the report of the Gloucester Farmers' Club for 1842, shows a profit of 19*s.* 5½*d.* per acre; for the last year he has informed us of still greater, and this upon a considerable scale. Mr. E. Solly, in the third volume of the "Transactions of the Horticultural Society," second series, reports an increase of more than ten bushels per acre; and on certain trials, which I reported in the second volume of the Royal Agricultural Society, I netted 2*l.* 17*s.* per acre.

In the "Transactions of the Highland Society" for July, 1843, in the report of some experiments (for which the Society awarded a premium of 20*l.*), made by Mr. Maclean, of Braidwood, on the increase of Hay, by the use of some of these manures, we find, among others, these results:

Manure applied.	Value of Increase, after deducting cost of application.
Rape Dust	£1 6 0
Guano	3 18 0
Saltpetre	4 15 0
Nitrate of Soda ..	5 0 10

Mr. Hannam, also, from near Wetherby, in Yorkshire, in his elaborate series of experiments, for which the Highland Society awarded a premium of 50*l.* (V. "Highland Society Transactions," No. 4, new series), gives, among a great variety of other interesting results, the following:

ON TURNIPS.

Manure applied.	Quantity used per acre.	Increase per acre.
		ton. cwt. stone.
Bones crushed..	16 bushels	8 7 4

I have selected the above examples from amongst the most successful, merely to show, when they do succeed, how great the profit may be to the farmer. But it by no means follows that there is not another side of the question; doubtless there is—failures perhaps are even more numerous. These manures are very often most uncertain and capricious in their effects—and I would strongly advise that no one should embark in them largely without first ascertaining, by trial on a small scale, the probability of their success, both as regards the crop and soil to which he thinks of applying them afterwards.

Presuming, then, that this is ascertained in the affirmative, these manures would seem to be of the greatest importance to the farmer; especially in those districts like our Cotswold hills, where farm-yard or town manure is seldom to be obtained in sufficient quantities. The introduction of a substance which could be purchased at any market-town, as for instance guano, at 11*l.* or 12*l.* per ton, from 2 to 4 cwt. of which per acre would go as far as a fair dressing of common dung, would be no inconsiderable boon to the farmer. Now this is all very promising—but it is not all gold that glitters. There are other drawbacks against which due caution must be exercised. When we have ascertained one year that the manure in question is likely to succeed on a given crop, we are by no means sure the next year of getting the genuine article; thus a serious loss to the purchaser may be incurred, not only in the article itself, but still greater on the year's crop, which, under different treatment, might have given very profitable returns. Let us see how the case stands in figures. Mr. Potter, in a little pamphlet entitled "A word or two on the use of Guano," tells us that it is sometimes found to contain 40 or 50 per cent. of inert sand. I have heard of some said to contain 65 per cent. Dr. Madden states, in one of his lectures "On the advantages of extended Chemical Analysis to practical Agriculture," that samples of nitrate of soda have been analysed and found to contain as much as 26 per cent. of common salt. I have seen a specimen which has also been analysed and contains more than 30 per cent. of foreign matter. Mr. J. B. Lawes, who, as a manufacturer of superphosphate of lime from bones, consumes two tons of bones a day, and is therfore a competent witness, states in the *Agricultural Gazette* that bone-dust is sold containing about one-third of lime. Suppose a farmer about to manure 20 acres with these impure substances, what would be his loss?

Manure.	Price per ton.	Impurity per cent.	Quantity used per acre.	Loss to Buyer on 20 Acres.
	£ s. d.		About	£ s. d.
Guano	11 0 0	50 Sand.	3 cwt.	16 10 0
Nitrate of Soda..	19 0 0	26 Salt.	1 cwt.	4 15 0
Nitrate of Potash	25 0 0	25 (27) Salt.	1 cwt.	6 5 0
Rape Cake	8 0 0	15 (27)	3 cwt.	6 8 0
	p. quarter			
Bones.....	1 0 0	33 of Lime.	20 bushels	16 10 0

Thus a farmer purchasing guano or bones for 20 acres of land would be a loser, first of 16*l.* 10*s.* on the article itself—and would only have half a crop on the land to which it was applied. Any one using 20 tons of foreign Rape-cake for food for cattle, which is said to be sometimes mixed with sand, if it contained only 10 per cent, would be a loser of 16*l.*, to say nothing of the injury which his cattle might sustain. It is by no means intended that these instances of impurity are altogether the result of adulteration. Indeed, it is known that most of these manures, in their natural state, are found mixed with large and varying proportions of foreign matter—and, if adulterated, that it is done before it reaches the hands of the merchant in this country; still, the loss to the consumer is the same, no matter how it happens. But even this is not the worst feature of the case; a few instances of disappointment will bring the genuine article into disrepute, from which it will not easily recover, and the advantages which might have arisen be lost to the country for years to come. The question then is how to prevent it?

The Scotch have formed a society for the purpose of employing a chemist at a salary of, I think, 600*l.* a year, who is to analyse for its members, at the reduced charge of a few shillings for each analysis, substances interesting to farmers; amongst others, especially these manures of commerce, so as to give at once their agricultural and commercial value. Thus a member of the association, who is desirous of testing any of them, has only to inclose a very small sample by post to the chemist, with the amount of charge for having any particular question answered, from 3*s.* to 6*s.*, or thereabouts, and in a few days he will receive an answer, which will probably save him from all the losses and disappointment before alluded to; and instead of paying for the article some 25 or 50 per cent. beyond its real value on a large order, he would be sure of his money's worth. Moreover, the chance of an impure article being ever sent into the country where a chemist is appointed, would be greatly diminished by the knowledge that it was likely to be analysed on its arrival. I am not about to propose to you to enter on any scheme so great as that of the Association of Scotland; but in a much smaller way it has struck me that results equally useful to the practical agriculturist may be obtained. I have applied to my neighbour Mr. Gyde, who, as an analytic chemist, from the variety of delicate and elaborate analyses in agricultural chemistry which to my knowledge he has performed, I believe to be as competent to the task as any one, at least in this neighbourhood, to know whether it would not be worth his while to offer his services to the Farmers' Clubs in this neighbourhood on such terms as would come within their means; and I am happy to say that he consents, upon being appointed chemist to any Farmers' Club, with an annual retaining fee of 5*l.* 5*s.* from each Club, to analyse for its members on terms similar to those of the Scotch chemist. I am aware that the subscriptions to Farmers' Clubs are very small, but I think, when the important objects above named are considered, there will be no difficulty in raising such a sum yearly by a subscription for the express purpose, from the richer members, if necessary. For further particulars I refer you to the letter of Mr. Gyde, advertised in this day's Paper, and if any Club think it worth while to encourage the scheme, I will thank their Secretary to signify the same to me, or to Mr. Gyde.—*W. H. Hyett, Painswick House, March* 26, 1844.—[This valuable article appeared in the *Gloucester Chronicle* of March 30th, as a letter to the Farmers' Club of the West of England, and we are glad to have the opportunity of publishing it here at the request of its author.]

ON THE ORIGIN OF MOULD.

As you have noticed a communication made by me to the Geological Society in 1837, on the Formation of Mould, I should be much obliged if you would correct an error into which I have fallen. In a postscript to that paper I state that marl was put on a pasture field, since ploughed, 80 years ago: I should have said 30 years, as I mistook the figures in the paper sent me. I found out this on visiting the place four years and a-half subsequently, and examining the old occupier of the farm. Wishing to ascertain the accuracy of the stated depth at which the marl now lies buried, I had three long holes dug in different parts of the field, and in each I found the marl, together with some cinders and broken pottery, in a layer 13 inches beneath the bottom of the potato-furrows, which were about four inches beneath the general surface; so that these substances are now buried at a depth of no less than 17 inches. They will never, probably, be undermined by the worms, to any much greater depth, as they almost rest on the general substratum of pure white sand. I particularly examined the occupier, whether the field had ever been ploughed to a greater depth than six or eight inches, and he positively assured me that it never had. My original informant, therefore, rather underrated the depth at which the marl now lies; although probably in the interval of four and a-half years, between our observations, some soil may have been removed by the worms from beneath the marl. In the other fields, formerly examined, I found that the layers of lime and cinders were, in almost every case, about an inch lower than they previously were. It was curious to observe in some of the holes how distinct three layers were preserved; the uppermost of cinders being two inches beneath the surface (on the former occasion one inch below), the middle layer of lime at four inches, and the lowest of cinders and burnt marl, at from 10 to 12 inches. I found this lowest layer wherever I dug, and likewise the other layers, but less regular, owing to different parts of the field having been limed and cindered at different periods. When digging in this field, after a long drought, I noticed, that one single clod of earth, about as large as a man's two hands, was penetrated by eight upright, cylindrical worm-holes, nearly as large as swan-quills, so that I could see through them. Now this shows the quantity of earth in a small space, which is often probably removed by the worms and brought to the surface. The boggy field mentioned in the postscript to my Paper, on which two years and a half before a thick layer of bright red sand had been strewed, and which, I was informed, was then buried three-fourths of an inch beneath the surface, I found four years and a half subsequently (*i. e.* seven years from the sand being put on) was exactly two inches beneath the surface. In that field (also rather boggy) which I have described in my Paper, as first reclaimed 15 years before, the burnt marl was buried at a depth of four inches; so that in these two cases the rate of sinking, or more properly of being undermined, has been nearly the same, namely, about two inches in seven years. In the fields, however, more particularly alluded to in this notice, in which the marl that was put on thirty-four years and a half before, then lay seventeen inches beneath the surface, the rate of being undermined has been much quicker, namely, three inches and four-tenths of an inch every seven years. This field is dry, and consists of black, poor, very light sandy soil. It has also been ploughed, which may make some difference; though it is clear, from the uniformity of the layer, that the marl must have sunk beneath the depth at which the plough could disturb it before the pasture had been broken up. I am surprised at the red sand on the most boggy field having been buried as much as two inches in the seven years, for I never saw a field on which there were so few worm-castings. One cannot, however, judge of the number of worms in a field from inspection at any one season.—*Charles Darwin, Down, Kent.*

ON THE CULTIVATION OF FLAX.—No. I.

The cultivation of Flax engaged the attention of the farmers of Great Britain and Ireland at an early period, and in certain districts of these countries few farms were without a portion of it, while in others it was scarcely known. Before the introduction of cotton fabrics into general use, the linen manufacture was necessarily one of much importance, and, in fact, it is so still, but in a different point of view. Since the days of which we speak, the manufacture has entirely passed into other hands. Then, the farmer was not only the grower of the crop, but, to a certain extent, the manufacturer also; it was invariably converted into yarn by the farmer's family; and, especially in the north of Ireland, it was also manufactured into cloth, the linen-weavers there being invariably small farmers. The Flax crop, therefore, in those days, was one to which a peculiar value was attached, not only as proving remunerating as an article of culture, but also as affording employment for the female members of their families in its subsequent manufacture. A small patch, at least, was grown with a view of supplying the materials for the manufacture of the household linen, which every frugal housewife knew the value of having done under her own superintendence.

The extent of land devoted to the Flax crop has been for many years past annually growing smaller; and, were it not for the late vigorous movements to extend its culture and introduce a better system of management, its cultivation would soon have been entirely abandoned. By the extension of machinery of late, the quantity of Flax consumed in this country, both for the home and foreign market, has greatly increased, and the growth of the crop having been neglected in this country, the small portion grown being also badly managed, the manufacturers were obliged to look to other countries for their supply. The consumption of oil-cake too, was considerable; and for this also the British farmer was dependent on the foreign market. In the year 1841, the importations of Flax alone amounted to about 80,000 tons, at an expense of from 5,000,000*l.* to 6,000,000*l.*, and if the sum paid for seed and oil-cake be taken into account, the annual outlay could not have been less than from 10,000,000*l.* to 12,000,000*l.** The importance of raising this supply at home was too manifest to escape the attention of those most interested in the matter, and the inquiry instituted with a view of ascertaining how far this could be done, gave the impetus to its cultivation, which is now so rapidly spreading itself throughout the country.

The cultivation of Flax in these counties had, indeed, for many years past been almost exclusively confined to the north of Ireland, but from the defective system of cultivation in general use there, and the still inferior method of manufacture to prepare it for the spinner, the sample produced was generally of a very inferior quality, and consequently brought a low price compared with that paid for the imported article. The small returns thus

* See Reports of the Belfast Flax Improvement Society.

obtained from the crop still further prevented the extension of its culture. Samples were, however, occasionally produced fully equal, if not superior, to any imported, clearly showing that by adopting a proper system of management, a superior article might be produced at home. So great, indeed, was the difference in prices, according to quality, that samples were occasionally produced in the Irish markets for which 7*l.* per cwt. were readily obtained, while the average price was considerably below half that sum. It was clear, therefore, that a proper system of management only was wanted to enable the home grower successfully to compete with the foreigner. The soil and climate of our own country was abundantly proved to be more favourable to the Flax crop than those even of the countries where the greatest perfection in its cultivation had been obtained. In the Flax-growing countries of the Continent, in Belgium especially, continued dry weather during the seed-time often renders the preparation of the land extremely difficult, and when this is imperfectly performed, Flax of a good quality is rarely produced. The alternations of sunshine, and shower so characteristic of our climate at that period of the season, obviates that difficulty, and when ordinary attention is paid to the preparation of the land, and the seed sown at a proper season, a good braird may almost with certainty be calculated on.

Premising these general considerations regarding the Flax crop, which is now occupying a much larger share of the attention of the farming community than it has done for many years past, I shall endeavour in a few papers on the subject to place before the readers of the *Gazette* the most approved practice both as regards its cultivation and manufacture. I do not, however, feel myself warranted in stating, as some of the advocates for the extension of Flax-culture have done, that there is not an acre of arable land in the country but will grow Flax of the finest quality. It is true that the Flax-plant has a rich range of soil, but like all our cultivated plants, there are soils to which it is decidedly unsuited, and on which its cultivation should not be attempted. There is perhaps no other crop which requires greater attention in the performance of every process connected with its culture and management, but when such attention is bestowed, there are few, if any, will yield a greater return. Nor need any fears be entertained that by its more general cultivation the supply would soon exceed the demand, as this cannot be the case for at least many years to come. The demand has been on the increase for some time past, and there is no good reason to suppose that it will not continue to increase with increased cultivation. An important part of the profits of the Flax-grower has hitherto in these countries been almost entirely neglected, namely, the proper management of the seed, which, of itself, often affords as large a return as some of our other cultivated crops altogether.

Having had more than ordinary experience in the culture and management of Flax, and being connected with the district in which the most important movement for the extension of its culture has been introduced and effectively carried into operation, I hope I may be excused the liberty of assuring my readers that the directions placed before them on the subject will be the result of experience, and that they may be implicitly relied on. I may also add that I shall willingly reply to any inquiry on the subject, through the *Gazette*, when the directions given may not appear to be sufficiently explicit. — *J. Sproule.*

ON THE SOIL AND CLIMATE OF THE SHORES OF THE MORAY FRITH.—No. III.

(*Continued from p.* 202.)

Gravel Banks and Subsoil.—A very remarkable feature of the North Highlands of Scotland, observable on every hill-side, and almost from the tops of the highest mountains to the bottom of our lowest valleys and sea-coasts is the general deep covering of loose sand and gravel over the rocky strata. Indications everywhere exist of the country having been long submerged beneath a great ocean, and it is extremely likely that the shapes of the hills and of the main valleys were impressed on the land before it arose from the deep. The summits of the highest mountains are found strewn over with rifted angular or but partially-rounded fragments (often different in composition from the rocks below), as if they had been for ages islands among the retiring waters; the glens beneath are studded on their opposing sides with numerous terrace-banks and gravelly barriers at various altitudes; and lower still, a general horizontal coast line of gravel invests the whole shores of the Moray Frith at an elevation of about 90 feet above the present high-water mark, which seems to indicate a period of repose in the waters at a time when they extended across the great Caledonian Valley, from Inverness to Fort-William, thereby throwing the northern counties into an island separated from the rest of Scotland. The lip of this general terrace-bank exactly coincides with the summit level of the Caledonian Canal; and the general features of the deposit are—its great regularity round all our coasts, its varying in breadth from a few yards to two or three miles, its being composed of sand and rounded pebbles which rarely exceed the size of a man's head, formed chiefly of granitic and primary rocks,—for the secondary softer strata seem to have been entirely pounded down into fine sand and clay; and sticking on the upper surface of the bank, or at least within a very few feet of the surface, large boulders of rock occur, often of many tons weight, and which appear to have been transported to their present localities at no very distant geological era, upon ice. There is a remarkable absence of organic remains either of animals or vegetables in these gravel beds, except on their very top, or connected with the layers of peat which cover them; but the rocky substances constituting the gravel can often be traced to their original beds, and the directions of the currents from which they were deposited can hence be determined. The scratches on the rocks below, and the component masses of the gravel in the neighbourhood of Inverness, and all along Nairn and Morayshires, demonstrate that the main current proceeded from the south-west extremity of the great Glen towards the north-east; and the primitive boulders from the interior of the country, strewn over the plains of Ross and Sutherland, indicate the same direction; while, on the north-west of Ross-shire, the current appears to have had a course more from the north. In the forms of the hills and valleys we can often trace the course of cross currents and eddies; and although the heterogeneous mixture of substances in the gravel demonstrates the extensive movements which occasionally and at first prevailed among the waters, still it would appear that there were long periods of repose, during which the clays and finer particles subsided; so that even the higher ridges frequently exhibit a remarkably good loamy subsoil. That the course of the waters tended generally towards the north is farther clear from most of the escarpments looking towards the south, and the declination of the ridges being in an opposite direction from them; while it would also appear that the southern front of the hills was most exposed to the currents, as it is a commonly observed fact among the farmers that the northern slopes of the ridges usually have the finest soil, and they are most abundant in clayish particles.

By far the greatest portion of the Agricultural districts in the north rests on the gravel beds and terraces now described, which thus form the common subsoil of the country; and from its open, porous texture and the general admixture of all manner of substances in its composition, that subsoil equalises much the productiveness of all the districts, and renders them less dependent than they would otherwise be on each peculiar or prevailing substratum of rock. In fact, the gravelly subsoil is, on an average, at least 10 feet deep, of which the debris of the immediately subjacent rock forms in general but a small proportion,—although it is remarkable that, on the whole, there is a much greater quantity of clay present than could be expected from the loose appearance of the beds. Indeed, a recent analysis of one of the commonest subsoils about Inverness has shown that it contains upwards of 60 per cent. of aluminous matter, which readily accounts for the rapid growth of trees in apparently mere sand-pits.

This paper having extended to a greater length than I expected, I must defer a sketch of the climate of the north of Scotland to another Number of your Journal.—*G. Anderson, Inverness.*

(*To be continued.*)

MECHANICS AS APPLIED TO AGRICULTURE.

By Mr. Cottam.

(*Continued from page* 203.)

The operations of Agriculture to be performed by machinery may be divided into five classes. 1st. Implements used in tilling the land and in the cultivation of the crops. 2dly. In harvesting the crops. 3dly. In preparing the crops for market. 4thly. Implements used in preparing the food for the stock on the farm. 5thly. Domestic machinery.

Under the first head will come the draining tools—the plough, the harrow, the cultivator, the rake, the roller, the drill, and the horse-hoe. Before I enter upon the implements, I will take the liberty of giving a slight sketch of the great improvement made by Mr. Smith, of Deanston—that of thorough-draining and subsoil-ploughing. This system will prove of great assistance to the Agricultural engineer, because the land can be laid all flat and even, will always be in a fit state to work, heavy rains will have a less injurious effect upon it (if any), and the hot sun in dry weather will not retard the performance of machinery as formerly. This system is clearly shown on the diagram; the drains are to be cut thirty inches deep and eighteen feet apart; the land may then be ploughed four or five inches deep, and subsoil-ploughed fourteen to sixteen inches more: this is only to break up and raise the soil, not to turn it up to the surface. The subsoil plough should follow the ordinary plough: it will take a great power to draw it at first, but it is evident that every year it will take less power to perform the operation. Land so drained and ploughed should be ploughed with a turn-rest plough, that the furrows may be all one way, and the land laid flat, so far as the natural undulations of the soil will permit it; in this state it will be easy to understand how this system will make wet land dry and dry land moist, in that state most congenial to the growth of plants. When the rains come, the water has not to flow from the ridges or stetches into surface drains, washing away all the manures and pabulum of the soil with it, but where it falls there it passes through to the drains, and becomes filtered in its passage, leaving all its virtues behind it; this shows that it is as beneficial to drain the hills as the valleys. If we compare this system with that of land not under-drained, but what is called well drained on the surface, and ploughed in high and narrow stetches (or lands), the subsoil has been what engineers call puddled, that is, trodden down till it is quite hard and impervious to water, and impenetrable by the roots of plants, for it has not been disturbed for years, never having been ploughed more than from four to six inches deep. When ploughed it is laid up in ridges or stetches, the narrow ones in seven furrows; but they are made in various numbers, so that in every five feet you have a drain a furrow wide. Now, if we observe this furrow in harvest time, we shall find if it is a wet season the crop in and on the sides of the furrow all perished, the straw short, and the ears of Corn small and unripe; in a dry season the crop will be dried up and equally as poor. The diagram will show the reason there is no depth of soil to hold moisture. Here, at the best, on the top of the ridge, we have but six inches deep, diminishing in the space of two feet six inches to nothing in the furrow; while in the new system we have sixteen inches of soil to hold moisture. If we wanted to keep anything moist, and we wet a blanket and laid it over it, and found it dry quickly, we should put on four blankets. Now this is a similar case; one has four inches depth of soil, and the other sixteen inches. In a dry season the roots can descend and obtain support. What an advantage does this mode of culture give to the implement-maker! He has a flat surface to work upon, and that in a dry state.

Mr. Cottam now compared the various ploughs, showing the improvements made upon them, referring to numerous models and diagrams, for want of which it would be impossible for us to give even an outline. He showed various ways of setting out the turn-furrow or mould-board of ploughs, as practised by different makers, and particularly one designed by the late Rev. W. Rham, in which, although apparently a beautiful curve, all the vertical lines were straight. He also explained Smith's, of Deanston, new turn-rest plough, and the way the sod was cut, raised, and turned over, referring to numerous mathematical diagrams. After going through the harrows and the cultivators in a similar manner, he compared Finlayson's, Biddell's, Wilkie's, Kirkwood's, Lord Ducie's, and his own, pointing out the advantages and disadvantages in working them. One harrow, said to be invented by Smith, of Deanston, and improved by himself, by serrating the discs (a sort of quoit-shaped instrument), attracted considerable attention. It was shown by the Dynamometer, that so great an improvement had been made in English ploughs, that they were now superior to the Scotch, by taking less draught, as 32 to 40. Mr. Cottam concluded by showing the great importance of every improvement in Agriculture. The importance of any improvement in Agriculture will be easily comprehended by the following calculation:—The extent of land under Wheat in the United Kingdom is about 8,000,000 of acres, and the average produce about 24 bushels per acre. Now if this average could only be increased to 27 bushels, this would yield 3,000,000 of quarters, which at the present price, say 50*s.*, would amount to the sum of 7,500,000*l.* It is not only in the Wheat-crop that an increase could be obtained by the new system of thorough draining and subsoil-ploughing, but all other crops; and the quantity of food for stock of all descriptions would be increased thereby.

ON INFLAMMATORY FEVER IN YOUNG CATTLE.

Inflammatory fever or quarter-evil, or, as it is also sometimes termed, black-leg, is one of the most fatal diseases to which cattle are subject, being exceedingly rapid in its progress, and seldom admitting of cure; never, indeed, unless the remedial measures are actively adopted at an early stage of the disease. Young cattle chiefly are its victims, and so rapid is its progress, that on being looked over in the morning the animals may appear as usual, and before evening one or more of them may be suffering from inflammatory fever, which may even have proceeded so far that decomposition has commenced in the part affected, after which a cure is hopeless. The farmer can never place much confidence in the success even of the best treatment for the cure of this disease; but he has much more influence in preventing its ravages than is *usually* supposed.

Inflammatory fever is now fortunately a disease of much rarer occurrence than formerly. In many cases I have known the rearing of calves altogether abandoned from the prevalence of this disease, and the probability of their being carried off by it before completing their second year. What appeared more surprising still, the animals making greatest proficiency in their growth were invariably those most liable to suffer. In other districts, however, it is comparatively unknown, especially where a uniform system of treatment is adopted in the feeding of the animals. A knowledge of the animal economy is of scarcely less importance to the farmer than that of the best systems of cropping, as his live-stock constitute the largest portion of his capital, and such knowledge would often save him from serious loss. It would show him that the disease to which we are now referring was the natural consequence of his violation of the laws of Nature in the treatment of his young cattle, and the penalty which he must pay for his defective management. His young cattle at one time are so miserably fed as merely to support life, and at another fed highly, the change in the quality of food being also effected in a short space of time. That this should produce a derangement of the system cannot appear surprising. In districts where Turnip cultivation is little practised, the young cattle are supported during the winter on straw, and that often of an inferior quality, from being improperly saved, with a run for a few hours each day over their miserable pastures; and so far have the animals been reduced during the winter by this treatment, that the first few weeks of the spring, after vegetation has made some progress, and the grass affords a full bite, produces such an effect on them that inflammatory fever seizes them and speedily carries them off. Those making most progress at the time are also most likely to become the victims of the disease, the reason for which is obvious. Though occasionally occurring at different periods of the season, yet nine-tenths of the cases of the disease which occur take place in the spring or beginning of summer, as at no other period does the system undergo such a change from a transition in the quality of food.

Though little can be done in the way of cure, yet it will

appear much may be effected by prevention. The more general cultivation of green crops to supply the cattle during winter with food, not merely to keep them alive, but also to promote their growth, will do much to render the devastations of this disease less formidable, or prevent its occurrence altogether. Many cases have come under my own observation in which this has, in a great degree, been effected by such means. I may mention one particular case, in which the rearing of young cattle was altogether given up, from the calamity of the young animals being carried off by inflammatory fever; but since the growth of Turnips was introduced on the farm five or six years ago, the farmer in question has again commenced rearing his calves, and the young animals being supplied plentifully with Turnips throughout the winter, not a single case of the disease has since occurred.

The advantage of early maturity in the rearing of live stock is now generally understood, and it is not a little singular that more effective means are not more generally employed to attain such a very desirable object. The farmer who does not maintain his young stock in a condition of progressive improvement from their birth until they are disposed of, very much neglects his own interests. It will not do to allow them to stand still, much less to retrograde in condition, at one period of the season, with the idea of making up the loss at another. This is false economy, to say the least of it; but it further subjects the unfortunate animals to disease, and that of the most active kind.

It is not my present purpose to enter into the treatment of inflammatory fever after it has made its appearance, as this must be reserved for another occasion. The foregoing remarks on the subject have been suggested by the perusal of the prospectus of an Association for Assuring the Farmer from Loss by the death of his Live Stock; but an exception is made in the case of the disease under notice. This exception would seem to indicate that the number of cases of inflammatory fever must still be great, otherwise, the conclusion of the Association has been arrived at on incorrect data. Though, as before remarked, the farmer can *do little* in the way of cure, he can do much in preventing the disease from at all making its appearance among his stock; therefore, the so general prevalence of this disease seems a reproach to the good sense of the farming community.—*J. Sproule.*

Home Correspondence.

Irrigation.—Liquid manure, and the waste of various drainings are the subject of frequent speaking and writing. Applications of this nature to land are usually effected by cartage. There is, however, another mode of applying liquid manure, which is seldom adverted to, and that is by irrigation. When once the land to be irrigated is formed for the purpose of receiving superficial water, the whole quantity of disposable water may be applied at a comparatively inconsiderable expense. The quality of water is a subject deserving much attention, where it flows from springs only, and in dry weather. In rainy weather, and in a cultivated country, most watercourses necessarily contain much fertilising matter, either in a solid state, or in solution, in addition to that which rain itself contains. Even in dry weather, where a stream is of considerable size, it usually receives some addition to the original springs which feed it, from various outlets in farm-yards and domestic buildings. There are, therefore, at least three conditions of running water. The first is its original quality as it comes out of the earth; in this state the temperature of the water is of great importance in its influence on vegetation. It is, perhaps, to this cause that the water issuing out of calcareous strata, such as chalk, produces in the winter months the continual growth of Grass, which would otherwise be torpid. It is true, these waters contain much carbonic acid gas; but even this, it is presumed, would scarcely affect vegetation in a temperature equivalent to the low mean temperature of the air; and thus water at a distance from the source, is said to lose much of its fertilising power. It cannot, however, be supposed that water, in running briskly along, exposed to the atmosphere, will lose much of its useful quality, otherwise than by its loss of heat; and this loss would not continue after the mean temperature of the air becomes greater than that of the earth, viz., between March and November. This agrees with what is observed in irrigated meadows: there is comparatively little growth in the winter months; but where the temperature of the air, and, consequently, the water, is greater as the spring advances, then vegetation proceeds with much activity. A long-continued irrigation in warm weather, however, produces unfavourable changes in the growing Grass, attended with an appearance of white scum, which dries of a leathery consistence. Perhaps some of your correspondents may be enabled scientifically to explain the nature of this substance. It is, however, very desirable that some more certain practicable mode of watering land should be made known. One person likes to water much, and another likes to water little. There is but one point upon which all good irrigators agree, and that is to keep the land thoroughly dry when it is not watered. But as to how long to keep it dry, and how long to water at a time, although questions material enough to be solved, no answer can be obtained. The second condition of running water is that which contains the washings and scourings of the soil through which it passes in rainy weather, commonly called land-floods. There can be no doubt of its good effects, nor that with reference only to this use of water, the irrigation should cease with the floods. The third condition which has been adverted to, partakes of both the former states of running water; it is that of a stream which in dry weather contains much adventitious matter. This water is, therefore, in relation to the more permanent nature of its constituents, nearly allied to the water of warm or calcareous springs, as containing the elements of vegetable life. Its application must depend on the previous questions being satisfactorily answered with regard to the proper mode, and intervals of application. Liebig, in his "Agricultural Chemistry," (page 159), refers to the very superior management and great produce of water-meadows in Nassau. He says the land is irrigated both in spring and in autumn, but no mention is made of winter-watering. One other remark should be made, and that is on the pernicious quality of some waters which have long continued stagnant, or which contain in solution the contents of metallic strata unfriendly to the growth of useful Grasses. There are, however, some waters which appear on analysis pure, and yet no good effect is produced by them. If these observations should obtain the notice of any of your more intelligent correspondents, it is hoped that some light will be thrown on this somewhat obscure subject.—*T. P.*

[With regard to the 2d description of streams alluded to above, it may be mentioned that most water-courses are affected by the causes there alluded to; and care should be taken not to avail one's self of the first autumn floods for the purpose of irrigation, as they contain the washing of ditches and waste places, and are generally loaded with the seeds of weeds.]

Lucerne.—As you have inserted the remarks of "Nicodemus" on the concluding paragraph of an article sent to the *Agricultural Gazette* by the Secretary of the Chepstow Farmers' Club, and as there is no probability that either of the gentlemen mentioned by him will take the trouble of replying to his uncourteous attack, made under an assumed name, I hope you will also insert these few observations addressed to "Nicodemus" on the subject. I allow that I am not sufficiently conversant with Agricultural matters to give such a decided opinion as "Nicodemus" has hazarded. That gentleman would have acted in a more praiseworthy manner, had he stated the extent of his own experience in the growth of Lucerne, both drilled and broadcast; the number of years he has grown it; the nature of the soil and subsoil; together with the situation and aspect of the land on which the crops were produced, with their weight on both plans; and then, without giving two gentlemen credit for wishing to mislead others, he ought modestly to have pointed out the superiority of the one he recommended, and to have inquired whether they had well-grounded experience to confute his arguments. Knowing the liability of men, though able and experienced, to form erroneous opinions, I will concede the point in dispute, though incapable of deciding the question, and suppose Mr. John Sandford and Mr. A. Hall are wrong in giving the preference to sowing Lucerne broadcast; still it is clear that they have only stated their own opinion, and that with moderation, founded on such knowledge as they have been able to acquire, and that they are both open to conviction, and ready to confess their error, when it is clearly proved that they advocate a wrong system.—*Nathaniel.*

Field Beet.—In several articles in your Paper reference has lately been made to the growth of Mangold Wurzel for milch cows; and as I can speak on the subject from my own experience, after growing it for several years, you will perhaps permit me to caution your readers against using it, if their object is quality in their milk, and not quantity. I have invariably found that it increases the measure of milk, but diminishes, to a great extent, the thickness of cream and weight of butter; whereas the use of Carrots or Parsnips keeps up the quantity of milk, and considerably increases the weight of butter. Perhaps this statement may induce others to communicate the result of their experience on the subject.—*A Cow Fancier.*

Chinese Agriculture.—[Notice of the Wheat tillage of China, communicated by John Smith, Esq., surgeon of H.M.S. Cambrian, coast of China.]—"Wheat is cultivated nearly throughout the whole of China; hence the difference in the time of planting, and its coming to maturity. In the southern provinces it is sown in November, as soon as the Rice crops or vegetables have been cleared away; and in the northern it is planted towards the end of October. In the former the harvest commences in April, and in the latter in May; in the Shantong and Chensi provinces it is not finished before the end of July; so that it requires above half a year to come to maturity. It is cultivated on almost every kind of soil, and on the slopes of the mountains, which are cut into terraces for the purpose. In the neighbourhood of Amoy (lat. 21° 25′) it is planted in the marshy grounds from which the rice crop has been removed; and the mean temperature of the months of January and February, 1843 (which were very wet) was about 56° of Fahrenheit. The coast about Amoy is extremely barren and unproductive, the soil being chiefly composed of disintegrated sand-stone, and the detritus of granite, naturally producing nothing but mosses, and a few stunted Pines and Laurels; by the industry of the Chinese, and the copious application of human manure, it is made highly productive; and cultivation is carried on to the very summit of hills 1000 and 1200 feet high, the slopes of which are formed into terraces, to prevent the soil from being washed away by the rains. Smut appears to be the only disease to which the Wheat is subject. Everything in the shape of a weed is most carefully removed, and the utmost attention paid to prevent any noxious influence from injuring the crop. The land is prepared in the ordinary manner when the autumnal rains have fully soaked it. Having been ploughed in a very loose manner, the clods are divided by a harrow, the pins of which have a cutting edge, which is drawn by a small ox, after which it is formed into deep and broad furrows, with intervening ridges for the reception of the plants, which, having been raised in nursery beds, are transplanted when about five inches high in bunches on the long ridges, so as to occupy only one half of the ground. In each bunch of the transplanted Wheat which I picked here (at Chusan) there were 29 plants or stalks; and a square yard contains 15 such bunches planted at equal distances. I examined 15 heads (ears) one from each stalk of the bunch, in their perfectly ripened state, and found them to contain as follows, 33, 45, 34, 49, 34, 40, 42, 32, 48, 45, 31, 33, 38, 34, and 44 grains each, giving an average produce of 38.8 per ear. An ounce avoirdupois contains 1067 grains (this gives 48.771333 to the apothecary's scruple, or 146.3213 to the drachm). The process of tillage is rather tedious, and the expense of ground considerable; but in return for this, the Wheat takes deep root, and is well nourished. The manure employed in some places is the cake left after expressing the oil from Mustard seed, human and other hair, lime from burned shells; but human fœces and urine constitute the prevailing manure, and are so highly valued that they are carefully preserved by every family, and sold at a high price. To such an extent is the economy of this manure carried, that, to prevent any possible waste, privies are everywhere provided in the towns, and those who have occasion for them, not only invited to enter, but paid for so doing with a small piece of money. All these several substances, with a vegetable expressly cultivated for the purpose, straw and weeds, are thrown into vats, of which several are placed for security at the door of every house, and left to ferment till required. Wheat is called by the Chinese "Syiy Nia," and Barley "Drow Nia," or "the poor man's grain;" the former being called, when speaking to us, "mandarin chow," chow or food. The latitude here (at Chusan) is 30° 0′ 20″, at Amoy 24° 25′ 0″; but the cold is both longer and more severe here than at Amoy during the season of Wheat. There is a Wheat here without a beard, a specimen of which I have. It is cultivated in the same manner as the other. The average weight of each ear in an undried state is 15 grains. Great attention is paid to the manuring and irrigation if the season happen to be dry. During the winter the Wheat remains very low, and no further attention is paid to it by the husbandman. In April and May the growth is extremely rapid; but the Chinese do not allow the crop to attain perfect maturity before they cut it, lest the grain should fall out. When cut it is left to dry, and the grain is then beaten out in a tub." Thinking it possible that the accompanying notice of the Wheat tillage of China might serve to amuse, if not to instruct the readers of the *Chronicle*, I send it to you, accompanied by one scruple of the Chinese Wheat, and the same quantity of Barley. The former is, I believe, the same with that described by my friend Prof. Desvaux, in his valuable "Mémoire sur les Froments cultivés en France, ou qu'on peut y cultiver," inserted in the first volume of the "Mémoires de la Société d'Agriculture, Science, et Arts d'Angers," page 347, under the name of "F. barbu de la Chine," (Triticum sativum Sinense); his account of which, however, is not very encouraging, as he says,—"This variety has never succeeded well; it is short," &c. In point of hardihood it is inferior to the Mummy Wheat of Mr. Tupper, of which I have three plants which have stood out all the winter without protection, in a pot outside my bed-room window; while the Chinese Wheat and Barley perished under similar circumstances, and I have only two or three plants left, which I sowed later and covered with a tumbler. However, it may answer as a spring variety, and admit of improvement by careful culture. I find 49 or 50 grains required to counterpoise a scruple. The Barley is six rowed, and an ear which I have is beautiful. The length of the ear, including the awns, is 5 inches, exclusive of them 3¾ inches, and each row contains 10 grains, giving 60 for the whole of the six rows; about 35 grains weigh a scruple. I have, however, in each case picked out the plumpest and largest grains. A Norfolk farmer will be amused at the Chinese method of thrashing in a tub; but, notwithstanding, some parts of the Chinese Agriculture may suggest useful hints, some for a Norfolk or a Lothian farmer; especially the attention paid to the eradication of weeds, and the value set upon human manure, which contains more nitrogen than any other. The offensive odour of this, which forms I believe its chief objection, may be corrected by the addition of powdered gypsum or other substances, which, by preventing the loss of ammonia as it arises from the decomposing mass, destroy the fœtor, and add to the value of the manure.—*William Hamilton, Plymouth.*

Pig Feeding.—Having for some years been a practical amateur feeder of pigs, and somewhat celebrated among my friends for my bacon, I willingly send you the result of my practice, together with the very simple mode which I adopt. First, as to the choice of sort, the description given by your correspondent "J. Steele" is not far from the mark; avoid large flapping ears, a long snout, and coarse hair. A long deep-bodied pig is most likely to fill up well at both ends. Purchase your stock for winter feeding about July; let them have the run of the wash-tub, refuse vegetables, and let them graze as much as you can afford. Let their sty be warm, thoroughly clean, and well ventilated, littered down regularly once a week, and well drained. If you brew, let them have the grains, but only whilst fresh. About the first week in October begin the process of fattening. First, on putting your pigs into the sty for good, wash them all with a good strong scrubbing-brush and soap and water; it relieves the hide generally, and tends much to their comfort. For their food, mix in a bucket only as much good fresh Barley-meal as your pigs (say three) will eat without leaving any—the meal to have just as much water, and that soft and cold, as will cause the meal to adhere [illegible] together, so that the pigs eat it and do not lap it up. Let your feeding-trough have a high back, so that there be no waste of food,

and let it be too heavy to be overturned. In the corner of the sty have a trough (a stone one is best, as least likely to be upset) filled every day with clean water, of which the pigs will partake with much relish; they will then lie down and sleep, a process greatly conducive to fattening. Give them their food about four or five times a day, as fresh as you can mix it, and only what they can consume at a meal. Let them out once or twice a week for an hour during the first month; occasionally give them a pound or two of coal-dust, which they eat greedily, and which certainly has some good effect on them. The second month give them every other day a peck of *chat* Potatoes, boiled or steamed, mixed with the Barley-meal; and the last fortnight, instead of the Potatoes, give them every other day about a gallon of Peas each; this will make the fat firm. In thus fattening three pigs, the third should pay or nearly so for the other two. The following is the expense attending this mode of feeding:—

	£	s.
Three pigs of about 10 stone each, 12 lbs. to the stone, 2*l.* 6*s.*	6	10*s.*
Barley-meal, 12 cwt., at 8*s.* per cwt.	4	16
Peas, 3 bushels, at 5*s.* per bushel	0	15
Potatoes, wash, &c.	0	5
	£12	15

Or 4*l.* 5*s.* per pig. The whole merit lies in never allowing the pigs to have more than they can comfortably eat at a meal, and their sleeping in a clean and warm sty during the progress of digestion.—*W. H. Hill, Pembridge, Herefordshire.*

Rooks.—I have been an attentive observer of animals and birds for many years, and I have in vain attempted to fix on the rook the character of a rogue in grain. I believe him to be grossly libelled when accused of eating grain; the question, I conceive, has been long decided by naturalists, that he is a feeder on worms, grubs, larvæ, &c. The mischief he does is this,—in grubbing up the ground newly sowed he stacks up the grain, and the larks and small birds take it away. A corn may occasionally adhere to a good fat grub, and such may have been detected in his unfortunate maw; but that he is a purloiner of grain I deny.—*W. H. Hill.*

Inland Railways and Agricultural Improvement.—To enable the Agriculturist to commence, and to avail himself of modern improvements, we know of nothing so necessary as a ready and cheap mode of transit. This is necessary for the advantageous disposal of his surplusage. Railway communication is the desideratum through the inland part of the country. Let us suppose a case, and how it is practicable to be made available, by an apparent sacrifice on the part of the landowners, and on the part of Government. Take the contemplated line from Carlisle to Edinburgh and Glasgow. This would open up a fine and productive country between the Atlantic and German Oceans, where there is at present no water conveyance. We shall admit that this line at first, for the sake of argument, could not support itself, or make any adequate return, so as to induce a company to undertake it. Well; the proprietors all along the line are to be especially benefited; and we shall suppose, in the first place, they agree to give a grant of the necessary ground excepting near Edinburgh and Glasgow, where it is very valuable, and very small properties. This would be a stimulant to the undertaking; and if, in addition, and on the abovementioned condition, Government could be induced to advance 25 per cent. of the then expense of the construction of the railway, on the security of the railway—*secundo loco* to the shareholders, who were to receive only a certain per centage upon their money—say 4 or 5 per cent.—we should soon see a railway between Carlisle and Edinburgh, and also between the former and Glasgow. The proprietors of the ground would be benefited by giving away, and the nation would be benefited by the advance made by Government, in so far as it would give employment. A right in reversion could be stipulated for in favour of the landowners, after ample provision was made for all contingencies, by a sinking fund or otherwise; and also a preference to proprietors who had supplied ground on the terms before mentioned, to take shares up to a certain period, and then to be open to the public; or these suggestions, or any of them, may be subject to modification. It may be said that entailed lands could not be alienated or given away; but the same Act of Parliament that authorised the formation of the line, could empower the necessary conveyance by the heir in possession, or otherwise provide for this, on the ground that it was beneficial to the estate, and consequently beneficial to heirs of entail. As this suggestion may appear to some Utopian, we may mention that Lord Panmure gave the necessary ground for the railway between Dundee and Arbroath, in so far as it passed through his entailed property, and he holds his estate under a very strict entail. Government gave 20,000,000*l.* for bettering the condition of the blacks. If it would give half this sum, or 10,000,000*l.*, to construct railways, it would not only better our condition, but would, in due time, receive a return for the advance.—*Amicus Humanitatus.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A MONTHLY Council was held, at the Society's House, on Wednesday last; present: the Right Hon. Earl Spencer, President, in the chair; Hon. Captain Spencer, Hon. R. H. Clive, M.P., T. R. Barker, Esq., S. Bennett, Esq., T. W. Bramston, Esq., M.P., W. R. Browne, Esq., E. Buller, Esq., M.P., F. Burke, Esq., H. Colman, Esq., F. C. Cherry, Esq., E. D. Davenport, Esq., H. Gibbs, Esq., B. Gibbs, Esq., S. Grantham, Esq., W. G. Hayter, Esq., M.P., W. F. Hobbs, Esq., J. Hudson, Esq., Sir John V. B. Johnstone, Bart., M.P., Samuel Jonas, Esq., Rev. C. E. Keene, G. Kimberley, Esq., J. Kinder, Esq., Sir Francis Lawley, Bart., W. Miles, Esq., M.P., P. Pusey, Esq., M.P., F. Pym, Esq., Professor Sewell, W. Shaw, Esq., J. V. Shelley, Esq., and C. Stokes, Esq.—The following gentlemen were elected Members:—

Chalcraft, William, Bramshot House, Liphook, Hants.
Wheable, Thomas, Mitchelmersh, Romsey, Hants.
Lindley, Urban, Radmanthwaite House, Mansfield, Notts.
Fitfield, John, Symondsbury, Bridport, Dorset.
Mathias, William, Lambert, Fishguard, Pembrokeshire.
Robbins, Col. T. W., Castle-Malwood, Stoney-Cross, Hants.
Stacey, George, Uxbridge, Middlesex.
Black, John, Marske, Guisborough, Yorkshire.
Rawlence, James, Heale, Woodford, near Salisbury.
Porquet, M. F. de, Iron Foundry, Hornchurch, Romford, Essex.
Pocock, Henry, Sowley, Beaulieu, near Southampton.
Martin, William, Paul's Grove, near Portsmouth.
Fifield, Job, Hill Park, Romsey, Hants.
Tichborne, Sir Henry, Bart., Tichborne, Alresford, Hants.
Plenty, Edward, Newbury, Berkshire.

The names of 16 candidates for election at the next meeting were then read.

FINANCES.—Mr. Raymond Barker, chairman of the Finance Committee, presented the monthly Report of the state of the funds of the Society; from which it appeared, that the invested capital amounted to 7,700*l.*, and the current cash balance on the 31st March, to 1,742*l.*

DISCRIMINATION OF SOILS.—Mr. Pusey, M.P., Chairman of the Journal Committee, reported the adjudication of the Society's Prize of 50*l.* for the best Essay "On the Indications which are practical guides in judging of the Fertility or Barrenness of Soils," to Mr. John Bravender, Land-Surveyor, Cirencester, Gloucestershire. Many attempts having been made to explain the productiveness of the soil by chemical or physical causes, without any decided result, it appeared desirable to the Society, in selecting this subject for one of their Prizes, that the researches of Natural Philosophy should be assisted by making them acquainted with those obvious signs, whether of colour, consistence, or vegetation, by which surveyors and farmers are enabled to give at once a practical opinion upon the probable nature of land which they inspect. Mr. Pusey further reported that the Judges had highly commended four of the remaining Essays in that class, namely, those bearing respectively the following mottoes:—"Truth needs no embellishment," "H. A. P." "Then cold and hot, and moist and dry, In order to their stations leap," and "Speed the Plough;" and the writers were requested accordingly to communicate their names to the Secretary. He felt much satisfaction in communicating to the Council the great improvement this year in all the Essays sent in to compete for the various subjects of the Society's prizes. The Essays were not only more numerous, but more clearly expressed, and, above all, of a more practical character. They were working better and better every year; a result highly gratifying to the Journal Committee, as indicative of the great interest taken by the members of the Society in advancing its important objects.

PROGNOSTICS OF WEATHER.—In reference to the prize of the Society's gold medal, for the best account or record of the prognostics or natural signs of changes in the weather, Mr. Pusey reported that the two Essays selected by the judges in 1842 for a twelvemonth's trial of the practical value of the rules they respectively contained, had been placed, as recommended by the Council, in the hands of Mr. J. C. Morton, of the Whitfield Example Farm, for that purpose; and Mr. Morton had informed him of the completion of the trial on a very extensive scale of observation; the results, however, being too numerous to admit of immediate reduction to a common standard of comparison. On the motion of Mr. Pusey, the Council resolved, that their best thanks should be given to Mr. Morton, and to each of those gentlemen who had so kindly undertaken to assist him in carrying out the objects of the Society in this inquiry.

ESSAYS FOR 1845.—Mr. Pusey laid before the Council the schedule of the subjects and amount of prizes proposed by the Journal Committee for the Essays of next year, viz.:—

10*l.*—On the advantages of One-horse Carts.
10*l.*—On the best method of Fattening Cattle.
20*l.*—On the best method of Reclaiming Heath-land.
50*l.*—On the Agriculture of Nottinghamshire.
50*l.*—On the Agriculture of Cornwall.
50*l.*—On the Agriculture of Kent.
20*l.*—On the cheapest mode of Establishing a Tile-yard.
20*l.*—On Catch Meadows.
50*l.*—On the Dutch method of Curing Butter.
20*l.*—On Fences.
20*l.*—For the best Experiment in Agriculture.

The special conditions annexed to each of the prizes, in reference to the general mode of treating the subject, and the distinct information required to be given on particular points, would be announced in the Appendix of the ensuing Part of the Society's Journal; the Essays themselves being required to be sent to the Secretary on or before the 1st of March, 1845.

(To be continued).

FARMERS' CLUBS.

Stirling.—On March 8 a lecture was delivered in the Court-house, by Prof. Johnston, On Soils and Specific Manures. Among other important statements made by the lecturer, we were informed how draining the soil and sheltering it will greatly increase the warmth of the earth, which will produce earlier crops, and cattle will require less food than they would do if they were in bleak situations. A farmer, to whom I afterwards spoke on this subject, believed such statements were quite true, and he added that cattle have a desire for bottom heat and sought for it. His cows, when they were feeding in a certain field where they required to be out all night, knew where the warmest part was, and came nightly to it; the field was well drained, but the most of it was a clayey bottom, and it was not to the hedge sides and hollows that the cows came at night, but to the most elevated part of the field; and that part was of a gravelly nature. The observation of the farmer and statement of the Professor, thus appears to harmonise. The Professor stated that the heat in the case of the dry soil entered and warmed it; in the moist soil, the heat was employed in evaporating moisture, and consequently keeping it cool.—*Peter Mackenzie.*

Inverness.—At the Annual General Meeting of this Society, the question, "What are the varieties of Oats best suited to the agricultural districts of Inverness-shire, and at what stages of ripening should the crops be reaped?" was discussed; and it was the general opinion, as summed up by the Chairman, that the Hoptoun and Sandy Oats are at present the varieties most in repute in this county—the former for the heavier and the latter for the lighter soils; that the Sandy Oat is superseding almost all the old varieties; and that recently the Hoptoun is, in its localities, giving way rather to the late Angus. Dr. Mackenzie, Kinellan, stated that, for some years back, he has almost exclusively reared the black Tartarian Oat, as one very prolific, much relished by horses, and one which meals well. The meeting was unanimously of opinion that the Oat crops should be cut about ten days before being fully ripe, not only to avoid the risk of shaking, and injury from wind and rain, but also because, when the grain is once fully perfected, the energy of the plant, instead of being thenceforward directed to the secretion of more farina, goes only to the protection of the seed, by increasing the thickness and toughness of the husk.—*Inverness Herald.*

Chepstow.—At the meeting on the 25th of March, the Member who was to bring forward a subject for discussion being unavoidably absent on business, Mr. T. Pride spoke on the best manner of draining land. He considered draining to be a matter of the first importance, and whoever delayed the process on land that required it was not only incurring a serious annual loss himself, but neglecting the performance of his duty to the community. He was convinced that it was only by long experience and closely observing the nature of the land to be operated upon, that any one would be competent, in the case of land wet owing to springs, to decide on the most effectual and economical method of removing the superfluous water. He confined his remarks to land that required parallel or thorough-draining, and gave his opinion of the best manner of effecting this desirable end. In the first place he was decidedly in favour of running the drains right up and down the fall, instead of what was called oblique or diagonal draining. He considered that the deposit from the water was much more likely to lodge in oblique drains, and consequently made them liable to stop the water and send it to the surface again. Where they were to be obtained he preferred stones to anything else for forming the drains. He used flattish stones at first, which are put in edgeways so as to form a channel for the water in the form of a triangle, with its base at the bottom, and then had the drains carefully filled up with broken stones, about two inches in diameter, to within twelve inches of the surface. He was laying his drains 18 to 20 feet apart, but in very stiff land he should not put them more than 15. He was now draining some land, 30 inches deep, on a small farm he had taken into his own hands expressly for that purpose, and in cutting the drains he found stones enough for the purpose. He paid 9*d.* for seven yards of drain, including cutting and filling; if the stones had to be carted of course it would cost him more, but at present this was the whole of the expense. He *should* recommend the drains to be from 30 inches to three feet deep; never less than the former. Mr. T. Perkins said he preferred diagonal draining, taking the main drain up the middle of the *fall*, and bringing the cross drains obliquely into it. He drained a piece of land with the fall eleven years ago, but did not find the remedy effectual. He had now cut other drains across, and completely dried the ground. He found all the drains open and running when they were cut through, but the land was not thoroughly drained by them. The first drains were only 20 inches deep, the others from two feet six inches to three feet. The system he followed was tile-draining.—A member stated that increasing the depth most probably caused the difference; and, had the first drains been deeper, he thought those across would have been unnecessary.—Mr. W. Baker said he once tried cross draining, which did not answer, but finding some benefit from the main drain, which went straight up the field, he put some more parallel with it and drained the piece of land effectually. He considered that draining with the *fall* was decidedly best.

In the course of a subsequent conversation on another subject, Mr. D. Baker said he intended to sow some cow Grass instead of red Clover, which a member advised him not to do on his land, because it was a shallow soil at a considerable elevation. He found it required good deep land to grow it to advantage, and then the produce was nearly equal to that of broad Clover, and the stem being solid, it did not cause hoven in cattle. He had tried it repeatedly on a shallow soil with very poor success.—*A. Hall, Hon. Sec.*

Reviews.

An Essay on the Growth and Management of Flax in Ireland, which obtained the Gold Medal of the Royal Dublin Society. By John Sproule, Author of a "Treatise of Agriculture." S. T. Machen, Westmoreland-street, Dublin.

WE have to direct the attention of our readers, in this day's Paper, to the first of a series of articles by Mr. Sproule, on Flax Culture; and we have great satisfaction

in doing so, after reading the pamphlet entitled above, for its author is evidently well qualified to teach upon that subject. It is a valuable practical treatise on the cultivation and manufacture of Flax, and enters most fully into detail on every necessary point.

Miscellaneous.

Adulteration of Manures. — Three different specimens of nitrate of soda, sold at 25*s.* per cwt., were submitted to analysis, when they were found to contain respectively 14, 25, and 26 per cent. of common salt! Now these specimens were purchased from extensive dealers in the article, and were contained in the bags in which it was imported, so that we have no reason for suspecting the honesty of the retailer; and it follows, therefore, that this shameful amount of adulteration must be effected prior to its being shipped for Britain. I would desire that you bear in mind, however, the *fact*, that the presence of common salt, even to this enormous extent, may be natural; but yet the imposition upon the British farmer is equally glaring, whichever be the case, as will be seen by the following statement regarding saltpetre. This article likewise contains common salt, though in much smaller quantities; but, in this instance, the fact is not attempted to be concealed. Every cargo is analysed at the India House before it is sold, and the per centage of salt marked upon it, and the amount of salt deducted from the lot purchased. For example, suppose the saltpetre contained 10 per cent. of salt, if a purchaser buys 100 cwt., he receives the 100, but only pays for 90. Here, therefore, there is no deception; but we would ask how it happens that the same is not done with nitrate of soda, and that three specimens containing from 14 to 26 per cent. of salt should all be sold at one and the same price? Why, if justice were done in this case, the specimen containing 26 per cent. should have sold at 22*s.* in place of 25*s.*, if that be the fair price for the lot containing 14 per cent.; and if, on the contrary, 25*s.* is the proper price for the pure article, those three lots should have sold respectively at 21*s.* 6*d.*, 18*s.* 9*d.*, and 18*s.* 6*d.* per cwt.*—*Dr. Madden, on the Advantages of Extended Chemical Analysis to Agriculture.*

Caution to Farmers.—On Thursday a lot of one and two-year old cattle belonging to Mr. Dumbell, 14 in number, were suddenly seized with illness while grazing in the meadow belonging to the Hills estate, situate at the foot of Lazy-hill, near this town (Douglas, Isle of Man), and in a few hours three of them died. Mr. T. Alston, an experienced farrier, was sent for with haste. On his arrival he instantly set about ascertaining the cause of sickness and consequent death. This he discovered by opening and examining the stomachs of the cattle that had first died, each of which was found to contain a quantity of the roots of common Hemlock. To save the 11 other animals, he immediately bled them, and administered pounded chalk and other ingredients in warm milk; and we are happy to say that he saved the whole of the remainder, 11 in number. It appears that the cause of the Hemlock roots coming within the reach of the animals originated in the drains throughout the meadow having lately been opened; and in turning up the earth, large quantities of the roots of this deadly poison, which abound in great quantities in one of the ditches, had been dug up, and thrown upon the surface. This should operate as a caution to farmers not to turn cattle into boggy pastures while the operation of clearing drains is being performed, as in such situations the presence of this poisonous root may almost always be suspected. — *Mona's Herald.*

Urate.—If the floors of stables or cow-sheds were strewed with common gypsum, they would lose all their offensive and injurious smell, and none of the Ammonia which forms could be lost, but would be retained in a condition serviceable as manure. This composition, swept from the stable-floor, nearly constitutes what is sold under the denomination of Urate. Manufacturers of this material state, that three or four cwt. of Urate form sufficient manure for an acre: a far more promising adventure for a practical farmer will be to go to some expense in saving his own liquid manure, and, after mixing it with burnt gypsum, to lay it abundantly upon his Corn-lands. For, in this way, he may use as much gypsum as will absorb the whole of the urine. Now, in the manufacture of Urate, the proportion of 10 lbs. is employed to every 7 gallons,—allowing the mixture, occasionally stirred, to stand some time pouring off the liquid, and with it nearly all its saline contents except the Ammonia. Urate, therefore, can never present all the virtues of the urine—100 lbs. of Urate containing no greater weight of saline and organic matter than 10 gallons of urine.—*Smith's Productive Farming.*

Indian Wheat.—The Wheat Committee of the Agricultural Society have reported that the question is one of the highest importance as affecting the interests of India, and recommend the Society to nominate a committee for the purpose of preparing memorials to the Board of Control and Court of Directors, urging the admission of corresponding advantage to grain from this country, as has already been conceded to that from Canada.—*Indian Mail*

* Messrs. Mark Fotheringill and Co., London, who deal extensively in nitrate of soda, inform me that they examine what they buy, and reject as "useless stuff" any specimen containing above 12 per cent.

Notices to Correspondents.

Bailey.—*W. P. T.*—It was advertised by Mr. Robt. Beman, of Donnington, near Stow, Gloucestershire.

Bokhara Clover.—*A. R. C.*—We have not seen it in any stage of its growth in which it could be useful for cattle. When very young it is a succulent plant, but it soon becomes woody.

Concrete Tiles.—*Subscriber.*—We do not know any work wholly on this subject; but you will find details connected with it in the Number of the "Farmers' Magazine" for August, 1842, and in the July Number of Stephens's "Book of the Farm" for that year.

Dibbling Swedes.—*W. P.* informs "W. S." that the method of transplanting Swedes which he recommends, was heartily recommended and fully detailed by the late William Cobbett, in his "Journal of a Year's Residence in the United States." Does "W. S." know whether Carrots, Beet, and Parsnips can be transplanted with success?

Drainage.—*T. T. Hawley.*—We have received none of the letters you refer to; and if you will favour us with their contents, they shall, as all applications do, receive our immediate attention.

Food of Plants.—*Rural Chemist.*—See Leading Article next week.

Gas-Water.—*Gonyn.*—It appears from your statement, that about equal weights of the gas liquor and sulphuric acid neutralise each other. If you are right, the liquor must be of extraordinary strength; every gallon must contain about 2 lbs. of ammonia. If you use 20 cubic yards of your compost per acre, put to every cubic yard of it one gallon of the neutralised liquor. You will thus apply 1½ cwt. of sulphate of ammonia per acre.

Grass.—*J. B. H.*—Your sheep-fed Grass land, other things being equal, is more likely to yield Hay than one that has been mown frequently. Potter's guano had better be applied in mixture with vegetable earth on Grass lands: you will thus be able to spread it more equally.

Guano.—*J. M'I.*—Guano is a good manure for land *out* of condition, whatever be the crop to be grown. It will be a useful manure for Flax.

Mortality among Cattle.—*a.*—We shall endeavour to meet your wish in the course of a Number or two.

Neapolitan Pigs.—*A. H.* is informed that Mr. France, of Hamhill, Worcester, has a herd of the pure breed.

Pigeon Dung.—*ἀμαυρὸς.*—Apply it to arable land, and plough it in at the rate of 10 bushels an acre, having first mixed that quantity with about a cart-load of vegetable earth.

Potter's Guano.—*Mudie.*—Drill the land up for Potatoes, and then having sown the guano, at the rate of two or three cwt. per acre, in the rows, mix it well with the earth, by means of a horse-hoe or otherwise, and plant the roots in the earth thus loosened and mixed, and cover up as usual.

Potatoes.—*Argus.*—There is no second-early Potato equal to Prince's Early.—*J. C.*

Salt.—*J. C.* can get from those who manufacture it from *salt springs*—the salt which burns on the pans—at a nominal price. Try 1 cwt. per acre. See Report of Bromsgrove Farmers' Club, next Number.

Salt and Lime.—*Archenfield.*—Dissolve 2 cwt. of salt in 80 gallons of water, and with this slake 20 bushels of quick lime; spread it abroad on a firm floor for a fortnight. It will probably deliquesce. Apply this quantity on an acre; mix it with plenty of mould before applying it on grass-land, and on arable-land plough it well in. Can any one give us their experience of this manure?

Soot and Salt.—*Anon.*—Apply it along the top of the rows before the Potato plants come through.

Superphosphate of Lime.—*A Subscriber.*—Six or eight bushels per acre of bones thus converted have been found equally efficacious with three quarters per acre in the ordinary condition.

Swedes.—*Young Farmer.*—You need not expect a crop on "*cold, wet, marshy*" land. It must be drained first.

Top-dressing for Oats.—*North.*—This depends on the soil. Nitrate of soda, sulphate of ammonia, at one cwt. per acre, or more probably guano at the rate of three cwt. per acre, will answer your purpose.

Top-dressing.—*A. V.*—Try nitrate of soda, 1 cwt. per acre, applied early in May. See Mr. Lawes's remarks in Leader. The same might be applied beneficially to Tares earlier. For Cow Cabbage next week. Parsnips are a better food than Beet for cows.

Trenching.—*H.*—By all means keep the top soil uppermost.

Whitfield.—*Vale of White Horse.*—Some of the sheep belonging to the Whitfield farm have been kept on other Grass lands the property of Lord Ducie, in the neighbourhood, during the summer. They have been paid for at the rate of 4*d.* and 6*d.* per head per week for tegs and ewes; and, on the other hand, cattle (2 years old and 3 years old oxen) belonging to the Earl of Ducie, have been kept on Whitfield farm during winter and spring, and they have paid for their keep (Swedes, Mangold Wurzel, and Straw) being half in yard and half in house, at the rate of 4*s.* per head per week. If these rates of payment were fair, then the fact that in settling accounts between the two farms there has always hitherto been a balance in favour of Whitfield, shows that a larger amount of stock might have been fed on that farm than was kept there. Mr. Morton's estimate of return from live stock has never yet been put to the test; the plan which he proposed to follow was not adopted, owing to circumstances which it is unnecessary to state here.

Worn out Land.—*An Old Farmer.*—Farm yard manure made by sheep or oxen fed on oilcake, roots, and straw, is the best material to apply. If you have not got it, or if haulage would be expensive, apply 3 or 4 cwt. of guano per acre, and mix it well with the soil. You will have to pare and burn the peaty turf; plough the land and harrow it to pieces, then apply the guano and harrow it in; cross plough, harrow repeatedly, roll, &c., and ridge up for Potatoes.

Miscellaneous.—*W. P., Taunton,* informs "A. H." that Mr. Clark, of Trinsbury Farm, near Romsey, Hants, has a herd of pure Neapolitan pigs.——And he informs "P. McKenzie" that "Spar" in Cornwall means Quartz.

*** As usual many communications have been received too late.

Markets.

SMITHFIELD, Monday, April 1.—Per stone of 8 lbs.

	s.	d.	s.	d.		s.	d.	s.	d.
Best Scots, Herefords, &c.	3	6	to 3	10	Best Downs & Half-breds	3	10	to 4	2
Best Short Horns	3	2	3	6	do. shorn	3	4	3	8
Second quality Beasts	2	10	3	2	Best Long-woods	3	2	4	0
Calves	4	0	4	8	do. shorn	3	0	3	4
Pigs	3	0	3	6	Ewes and second quality	3	0	3	4

Beasts, 2820; Sheep and Lambs, 27,140; Calves, 63; Pigs, 340.

A less demand for Beef and Mutton we do not remember for a very long time than has ruled here to day; it is greatly to be accounted for by the sudden setting in of warm weather, which invariably has this effect. Having also a considerable supply, the prices have suffered a decline of fully 2*d* per 8 lbs, and a very great many cannot be disposed of at that reduction; towards the close of the day several Beasts were sold at a little under our quotations—still, a very large number remain unsold, of both Beasts and Sheep, especially the latter. A great many of the best Downs did not make more than 4*s*, although some few choice ones made 4*s* 2*d*, and it was difficult to realise 4*s* for the best Long-wools. Ewes and plain Sheep were scarcely saleable. The Lamb trade presents an improving aspect, and several small good quality are sold at 7*s* per 8 lbs, large ones at from 5*s* 8*d* to 6*s* 8*d*. Veal is a very heavy trade, and but very few Calves realise our highest quotation. Pigs are also lower.

Friday, April 5.

This being Good Friday, the most interesting feature of to-day's market is the show of Lambs, and the trade in that article. This is considered the first day of the regular trade in Lamb. We have noticed a larger supply in former years; there is, however, sufficient to meet the demand—indeed, a few remain unsold; the very best are worth from 6*s* 8*d* to 7*s* per 8 lbs, and larger ones as 5*s* 8*d* to 6*s* 4*d*. In other kinds of stock very little is doing, and in what is sold we cannot notice any difference in price from Monday's quotations.

Beasts, 778, Sheep and Lambs, 6990; Calves, 316; Pigs, 220.

41, West Smithfield.

HOPS, Thursday, April 4.

There is no alteration in the Hop Market since last week.

Mid & East Kent Pocks	6	0	to 10	10	Sussex Pockets	6	6	to 7	8

COVENT GARDEN, April 6.—Owing to the continued fine weather during the week, the market has been well supplied with most articles; and, generally speaking, there is not much alteration in their prices. Pine-apples are sufficient for the demand, and they are tolerably good in quality. Hothouse-Grapes are supplied in small quantities; they are offered at about 15*s.* per lb.; Portugals are plentiful. Good Apples are scarce; they have not altered in price since our last Report; the best dessert varieties are offered at about 28*s.* per bushel. Pears also continue to bring nearly the same prices as last week. Oranges are good, and very plentiful. Lemons are sufficient for the demand. Chesnuts are abundant, and are offered at last week's prices. Vegetables are, for the most part, plentiful, and they continue to improve in quality. Broccoli is good; it is offered at nearly the same price as last week. Savoys are now over for a season, and Brussels Sprouts are getting scarcer. Greens are still sufficient for the demand. Carrots and Turnips are abundant, and good in quality. Seakale and Asparagus are well supplied. French Beans are sufficient for the demand. Rhubarb of good quality is abundant. A few excellent Cucumbers are in the market; they are offered at nearly the same prices as last week. Strawberries are becoming more plentiful. Frame Potatoes bring about 3*s.* per lb. Among Cut Flowers are Erica Willmoreana, Euphorbia jacquiniflora, Gardenia radicans and florida, Acacias Azalcas, Camellias, Pelargoniums, Cinerarias, Fuchsias, Primulas, Lily of the Valley, and Roses.

FRUITS.

Pine Apple, per lb., 8*s* to 10*s*		Almonds, per peck, 6*s* to 7*s*	
Grapes, Portugal, per lb 1*s* to 4*s*		Sweet Almonds, per lb., 2*s* 6*d* to 3*s*

POTATOES.—Southwark Waterside, April 1.

The weather since our last report has been very fine, which favoured the growth of vegetables, causing a depression in our market. Several samples moved off tardily, at terms of this day week; on some samples a reduction was obliged to be made before sales could be effected. The Farmers are still employed with sowing their spring crops. Several cargoes during the past week have been shipped from Perth to Goole for plants. Notwithstanding, there has been some arrivals from those parts, also from the Channel Islands and Devonshire, and from the inland of Sussex by Railway, and by barges from Kent and Essex. Although the supplies have been limited, they are fully equal to the demand, and the annexed quotations were barely maintained.

York Reds	—	—	80*s* to 90*s*	Kent and Essex Whites	60*s*	70*s*

RENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance, can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of Iron will be found cheaper than of any other material. MR. RENDLE, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

HORTICULTURAL BUILDING & HEATING by HOT WATER.

J. WEEKS & Co., ARCHITECTS, &c., Gloucester-place, King's-road, Chelsea, Hothouse-Builders and Hot-water Apparatus Manufacturers, beg leave to inform the Nobility and Gentry that their business, which has been extensive throughout the country for many years, is entirely confined to the BUILDING OF HORTICULTURAL ERECTIONS of every description, and the HEATING of them by HOT WATER.

CONICAL and other BOILERS of all sizes; their largest consumes but a small quantity of fuel, only requiring attention once in ten hours, and will heat a range of Forcing-houses 300 feet in length.

Their improved plan of BOTTOM-HEAT FOR PITS, by means of an open trough under the bed, is now being universally adopted.

References may be had, and their works seen at most of the Nobility and Gentlemen's Seats in the country, nearly the whole of the London Nurseries, and a great variety of Horticultural Erections and Hot-water Apparatus, Models, Plans, Estimates, &c., at their Horticultural Manufactory, Gloucester-place, Chelsea, near Sloane square.

BURBIDGE AND HEALY beg respectfully to inform the Horticultural world that they are quite ready to supply their new BOILER, of every size. They have now fixed a sufficient number to warrant them in stating that what they put forth as the qualities of their Boiler and Furnace arrangement may be perfectly relied upon: they have put up one at the Horticultural Gardens, where B. and H. believe it is considered to answer as represented; they have also fixed it in connection with a new description of Iron Tank, which combines the qualities of the round pipe and the open tank, which may be pronounced the perfection of a Heating Apparatus for Horticultural purposes, particularly for Graperies, Epiphyte-houses, Melon-pits, &c., &c. The arrangement is such that any gentleman or gardener may have the whole constructed so as to be put together with the greatest facility by the gardener, first sending a correct plan to 130, Fleet-street. A Prospectus may be had detailing the prices, &c.

THE CONICAL HOT-WATER BOILERS, invented by J. ROGERS, Esq., may be obtained of any size from JOHN SHEWEN, Ironmonger, &c., Sevenoaks, Kent.

J. SHEWEN having had every opportunity afforded him by an extensive practice to bring this apparatus to perfection, begs to offer it as most efficient and economical; it may be seen at Messrs. Chandler & Sons' Nursery, Vauxhall; Messrs. Loddiges', Hackney; Messrs. Henderson's, Pine-apple-place, Messrs. Veitch & Son's, Exeter; Mr. Pontey's, Plymouth; the Royal Botanical Society's Gardens, Regent's Park; and at the Gardens of the Horticultural Society of London. Considerable improvements have been effected since last season, particulars of which are in course of preparation.

GUANO, PERUVIAN, &c.—The above Manures, also Potter's Guano, Nitrates of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.

Lists of Prices, with Synopsis of mode of use, on application to MARK FOTHERGILL, 40, Upper Thames-street, and 5, Railway Place, Mark-lane, London.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J. MYERS AND CO., LIVERPOOL; And by their Agents, COTESWORTH, POWELL, AND PRYOR, LONDON; GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL. 47, Lime-street, April 5, 1844.

GUANO ON SALE BY THE IMPORTERS, JOHN BOYD & Co., Wellington Chambers, London bridge, Borough.

PERUVIAN GUANO, of first quality, and in any quantity, direct from the Bonded Stores. Also African GUANO and Nitrate of Soda.—Apply to H. ROUNTHWAITE and Co., 6, Cable-street, St. George's Crescent, Liverpool.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing a more rapid vegetation in Plants than any substance known. It may be had at Mr. LAWES' Factory, Deptford Creek, price 7s. per cwt. Phosphate of Potash, 15s. per cwt.
" Soda 12s. "
" Magnesia 9s. "
" Ammonia 1s. per lb.

*** Super-phosphate of Lime in a concentrated form may also be procured of Messrs. WARNER, 28, Cornhill, and other Seedsmen, in 7 lb. packets, price 1s.

TO AGRICULTURISTS.

ENGLAND INDEPENDENT OF THE WORLD FOR CORN.

THE attention of the Agricultural Interest, at this momentous crisis, is requested to the great importance of LIQUID MANURE, and the ease with which it may be appropriated, by the use of FOWLER'S PUMPS, made expressly for the purpose, either portable or fixed; Garden, Ship, and Barge Pumps; also, those for Distillers, Brewers, Soap-boilers, and Tanners, for hot and cold liquor. Pumps kept for Hire, for Excavations and Wells, Buildings heated by hot water, for Horticulture, and every variety of manufacturing purposes. The trade supplied on advantageous terms, by BENJAMIN FOWLER, Engineer, &c., 63, Dorset-street, Fleet-street, London.

ASPHALTUM in its pure state, with all the material and instruction how to prepare, or if required, the labour performed at a moderate charge.

TOBACCO ASHES.—A few Tons of Tobacco Ashes to be Sold at 3l. per ton, convenient for land or water carriage.—Apply to J. A. HUBBARD and SON, 20, Harp-lane, Tower-street. All Letters prepaid.

THE URATE of the LONDON MANURE COMPANY, 5l. per Ton. It is with the greatest satisfaction, after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By promoting a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops. The Urate may be sown broadcast, or which is preferable, by the drill, at the rate of one ton to three acres, and it is desirable it should not be placed more than two inches below the surface. As a top-dressing for Wheat the Urate has been used with great advantage. Gardeners and Florists will find it very useful for Dahlias and other roots. Full particulars and Testimonials will be forwarded on application. Genuine Peruvian Guano; Phosphate and Sulphate of Ammonia; Gypsum and every other artificial Manure.

EDWARD PURSER, Secretary, 40, New Bridge Street.

NEW CHEMICAL MANURE.

HUMPHREYS'S FARMERS' COMPOUND, *stronger than Guano, and without its caustic rankness.* Samples on view at the Royal Polytechnic Institution. On Sale with the following Agents:—THOMAS GIBBS and Co., by appointment Seedsmen to the Royal Agricultural Society of England—corner of Half Moon-street, Piccadilly; COTTAM and HALLEN, Agricultural Repository, Winslow-street, Oxford-street; BURCHFIELD, Smithfield; BATT and RUTLEY, 412, Strand; CLARK, Bishopsgate-street; CHARLWOOD, Covent Garden; FLANAGAN and SON, Mansion-house-street; FOTHERGILL, 40, Upper Thames-street; HURST and MCMULLEN, Leadenhall-street; LOCKHART, Cheapside; WILLIAM and JOHN NOBLE, Fleet-street; W. J. NUTTING, Cheapside; WEDLAKE, Fenchurch-street; SAMUEL HOWARD, 38, Mark-lane; WHITE, Phœnix Wharf, Blackfriars; ALLEN, Shrewsbury; COPEMAN and Co., Wells, Norfolk; DICKSON and Co., Edinburgh; T. S. KING, Rochester; W. F. MOLESWORTH, Danbury; W. MADDOCK, Tunbridge Wells; W. E. RENDLE, Plymouth; THOMSON and Co., Macduff, near Banff; THOMAS WATKINSON, Market place, Manchester. Price 12s. per cwt.—DAVY, MACKMURDO, and Co., Manufacturing Chemists, 100, Upper Thames street, London.

IMPORTANT TO AGRICULTURISTS AND OTHERS.

ANALYSES OF SOILS, MANURES, &c. are conducted by MR. MITCHELL, Analytical Chemist (late of the Royal Polytechnic Institution), No. 5, A., Hawley Road, Kentish Town.

GLASS SUPERSEDED for HORTICULTURAL PURPOSES by WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, rendering Muslin, Calico, or Linen, for the Frames of Greenhouses, Pine, Melon, or Cucumber Stoves, &c., impervious to rain or moisture, admitting light equal to Glass, much warmer, and the plants never burn under it.

Noblemen, Gentlemen, and Gardeners will, by using this composition, have the only effectual protection for their Fruit-trees during the blooming season; it is a certain defence from frost, sleet, wind, and blight; its transparency admits the general beams of the sun, with abundance of light, which causes the bloom to expand with increased luxuriance, the fruit to set and swell more freely, much earlier, and a crop of fruit to any extent may be warranted. The covering not to be moved by day (except to thin the Fruit, which will be necessary), till the month of June. It is recommended that the Calico be prepared early, so as to be thoroughly dry before using.

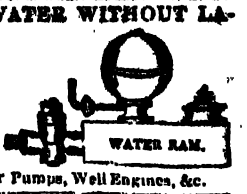
Sold in Bottles, with directions for use, pints, 2s. 6d., quarts, 4s. 6d. each. One pint is sufficient to coat four Frames twice over, each Frame to be 5ft. by 3ft. 3in., or thereabouts. Prepared by GEORGE WHITNEY, Chemist, Shrewsbury. Seedsmen, Florists, and Merchants supplied by Mr. W. BAILEY, Chemist, North-street, Wolverhampton. Appointed Agents:—Messrs. BUTLER and MUCKLEY, Covent Garden, where a sample of prepared calico may be seen; Mr. WATKINSON, Market-place, Manchester; PAGE and SON, Southampton; T. and C. WHALLEY, Nurserymen, Liverpool.

Agents wanted for London and the country.

KEENE'S PATENT MARBLE CEMENT.—This CEMENT is particularly adapted for the Walls and Floors of Conservatories and Greenhouses, being calculated, from its extreme hardness, to resist the wear incident to ordinary Plastering. For Floors it has a threefold advantage over Stone paving. 1st, in its lightness; one inch in thickness of KEENE'S CEMENT sufficing where 2 to 3 inch flagging would be employed. Next, in its appearance, combining, as it does, the hardness of stone with a uniform colour and even surface free from joints; and lastly, in economy, being one-third the price of Portland paving.

The most conclusive evidence can be given of the utility of KEENE'S CEMENT for these purposes by the Patentees and Manufacturers.—JOHN BAZLEY WHITE and SONS, Millbank-street, Westminster.

THE RIGHT OF PATENTING a valuable INVENTION for Ireland and Scotland for SALE. The Invention is an improved method of making Pipes, Tubes, and Tiles of Clay or other plastic substance, of any bore and any length. The uses to which they would be more particularly applied would be Draining, Sewerage, Conducting Water, Heating Greenhouses, Chimney-pots, &c. The Inventor reserves to himself the Patent for England. Any person interested in Draining in Ireland or Scotland would find the present opportunity worthy attention. Address, with real name and address, "DRAINER," at Mr. Scares', 44, High Holborn.



HORTICULTURAL IMPROVEMENT.

READ'S PATENT GARDEN SYRINGE, for the invention of which he has been honoured with the Silver Medal of the Royal Horticultural Society, as being the best Instrument ever offered to their notice. J. R. has IMPROVED the above by an additional branch to turn in every direction, so that water may be dispensed into all pots in Conservatories, in a perpendicular direction, resembling a gentle shower or dewfall, and in any quantity, from a pint to a table-spoonful. Likewise small Machines, Pails, Trucks, and Garden-Engines of every description, that will discharge water in a continuous powerful stream, made on the most improved principle, and may be worked with half the usual labour required for other engines now in use. The above are the best adapted for destroying insects, which make such deadly havoc on all choice Fruit-trees and Plants in Gardens, &c., which the Patentee (from 31 years' experience in Gardening, and 23 years in manufacturing and improving instruments) can safely warrant. May be seen and proved at 35, Regent Circus, Piccadilly.

N.B. None are genuine, except stamped with the words—"READ'S PATENT."

HENRY HUNT'S PATENT GARDEN POTS and STANDS, for effecting improved Drainage and Draught of Air. Patronised by Royalty and 30 Metropolitan and Provincial Horticultural Societies. Wholesale and Retail Depôt, 29, Queen's-row, Pimlico. The opinions of the Horticultural and Scientific Press, with priced Cards, forwarded on application, post-paid. Nurserymen in provincial towns appointed Agents.

RAMS FOR RAISING WATER WITHOUT LABOUR, WHERE A FALL CAN BE OBTAINED,

FOUNTAINS of every description. Specimens of the Fountain to be seen at the above address.

Also a Ram fixed on the premises. F. ROE, 70, Strand, London.

Every kind of Garden and other Pumps, Well Engines, &c.

MOST IMPORTANT TO FARMERS AND GRAZIERS.

GIBBONS' DISINFECTING OINTMENT, a most effectual and perfect cure for Epidemic and Foot-rot in Sheep; also for Epidemic and Foul in Cows' Feet, and for the Grease and Thrush in Horses; prepared only by HENRY GIBBONS, Agricultural Chemist, Wolverhampton.

This Ointment effectually destroys the American grub on Fruit-trees. Sold by all respectable Druggists in Town and Country, in packets at 2s. 6d. each. Mr. William Bailey, Manufacturing Chemist, North Street, Wolverhampton, is appointed Sole Wholesale and Shipping Agent.

ORNAMENTAL WIREWORK FOR THE GARDEN.
390, Oxford-street, London.

G. B. THOMPSON begs to tender his acknowledgments to the Nobility and Gentry who so kindly and liberally patronised his Manufacture of Ornamental Wirework, during the past years, and begs respectfully to remind them that with the opening season he has prepared an extensive assortment of Useful and Fancy Articles, suited to the Greenhouse and Flower-garden, and invites them to an inspection of his newly-arranged and well assorted stock of Flower-baskets, Trainers, Borders, Stands, Garden Arches, Temples, Vases, and durable Cast iron Garden Chairs and Seats, with his well-known and generally-approved Water-pot, fitted with finely-perforated roses, suited to the varying texture of different Plants; Hothouse Engines, Syringes, Fumigating Bellows, and all other Horticultural Tools and Implements of the most novel and improved manufacture. Game and Cattle Fences in variety.

LEVEL.—This Instrument, the invention of a Gentleman extensively engaged in Draining, is confidently recommended for its simplicity and cheapness; it requires only one person to use it, and gives the rise and fall in land as well as the level, and is also adapted for giving a uniform fall to drains. Each Level is packed in a case 18 inches by 3. Price, 2l. Direct to W. B. WEBSTER, Hounsdown, near Southampton.

100 CUCUMBER AND MELON-BOXES AND LIGHTS for Sale. One, Two, and Three Light Boxes and Lights of all sizes ready for immediate use—best materials; packed and sent to all parts of the Kingdom by JAMES WATTS, Sash Manufacturer, and Hothouse Builder, Claremont-place, Old Kent road. Garden Lights glazed and painted complete from 1s. per foot.

BEE-HIVES.—GEORGE NEIGHBOUR & SON beg to inform their Apiarian friends that they have prepared for the season a large supply of "Nutt's Patent Bee-hives" (for the sale of which they are the only authorised agents), in which are embodied all the recent improvements. Their selection now comprehends most varieties in general use at the present time, including the "Single Box Hive," the "Ladies' Observatory Hive," the "Improved Cottage Hive," with glasses, &c., from either of which the produce may be taken at any time of the gathering season, without destroying the Bees.

G. N. & SON have also Glass Hives, and other articles connected with Bee management, a catalogue of which, with drawings, may be obtained. Letters of inquiry must have postage stamps inclosed.—Apiarian Depot and Honey Warehouse, 127, High Holborn, London.

NUTT ON BEES, Fifth Edition, now Published.

Warner's Incomparable Large, late Marrow Peas, 2s. per quart. Potter's celebrated Liquid Guano, in quart bottles, 1s 9d. each.

VEGETABLES.—Turnip-rooted Chervil, very delicious, 6d. per paper; Potatoes, new early American, a very superior kind, 3s. per peck.

W. and W. beg to refer their friends to their list of New and Choice Flower and Vegetable Seeds in *Harrison's Floricultural Cabinet*, and the *Gardeners' Chronicle* for April and the preceding months; also to inform them they have now ready a Choice Collection of Herbaceous and Rock Plants, including all the New Varieties.

A General Catalogue of Garden and Flower-seeds may be had, on application by post, as a single letter.

WM. JOHN CORMACK, Nurseryman, Seedsman, and Florist, by Appointment to the Royal Horticultural Society, New Cross, Surrey, and Market Gardener, Florist, and Agriculturist, begs to call the attention of the Nobility, Gentry, and Agriculturists to the establishment of GARDEN FIELDS for Permanent Pasture, and Agricultural Machinery, Plants, Grains, &c. (on the premises adjoining), conducted by his partner, the late Mr. George Sinclair, Author of the "Hortus Gramineus Woburnensis." Upwards of 25,000 acres have been converted to permanent pasture at this establishment with the greatest success. Parties finally intending to sow permanently requested to state the nature of the soil. Mangold Wurzel, Carrot, and Turnip seed of excellent sorts, saved from transplanted bulbs. Garden and Agricultural Seeds of the best quality and most approved kinds. N.B.—Cormack's British Queen and Prince Albert Peas, at 2s. 6d. per quart.

J. G. WAITE, Seedsman, &c., 1 & 4, Lyre Street-hill, Hatton Garden, London, begs to refer the readers of the *Gardeners' Chronicle* to his priced list of Seeds which appeared in this paper of March 23, p. 191.

Agriculturists and the Farming community generally, will perceive his prices of Turnips, &c., are quoted much below all other houses in the trade; but at the same time they will please to bear in mind they are second to no one, in point of Stock and growth.

E. H. FULLER begs to call the attention of the Public that he intends exhibiting at the Chiswick Show, the following new and distinct Varieties of Verbenas, which have been universally admired, and subscribed for at, Exhibition.—*Vide Gardeners' Chronicle*, Oct. 14, 1843, p. 726.

E. H. FULLER, No. 9 (formerly No. 4), "brilliant rich purple, with a white eye, the best of its colour we have seen."—Plants in April, 1s. each.

No. 2, LUCASII, "delicate pink, clear and good."—3s. 6d. each.

No. 4, LOUIS PHILIPPE, "rose-purple, clear and steady in colour, a good variety."—Plants 2s. 6d. each.

"These flowers are distinguished by having the colours very clear, not dirty nor mealy, as it frequently happens. The flowers are rather small, but this may arise from want of better cultivation."

The usual trade allowance if three or more plants are assigned. All orders will be sent post-free, or by coach, paid to London. A Catalogue of Fuchsias, Geraniums, &c. &c. will be forwarded by post on application.—Worthing, March 14, 1844.

BULB CUCUMBER-GLASSES, for Watering by Evaporation during the growth of the Fruit, 2s 6d to 3s. 6d. each; GRAPE GLASSES, with holes, 1s 9d to 2s 6d each; BEE-GLASSES, 1s to 2s 6d each. Cylindrical CUCUMBER-TUBES, from 6d. to 4s. each; PROPAGATING GLASSES, Green, 1s per lb.; white, 1s 2d per lb., or 2s 6d to 24s. per dozen; FISH-BOWLS, from 1s 6d. each, ditto, with hole in the bottom for Fountains, 2s 6d per lb., at APSLEY PELLATT'S Falcon Glass Works, Holland street, Blackfriars. Orders from the country, accompanied with a Post-office order, will meet with prompt attention.

MECHI'S ELECTROTYPE FORKS & SPOONS. After a most careful examination and consideration, I have come to the conclusion that I can safely warrant and recommend this article as being superior to the plated, or German silver, or any other kind of plating. The article being in a finished state, the silver is deposited on it by electricity, without any solder, so that when the edges wear in course of time, there is no blackness or unsightliness and no one could distinguish between the worn and unworn parts, the article on which it is fixed being hard white metal, so near the colour of silver that electric fluid amalgamates inseparably the two bodies, so that nothing can divide them. Long continued wear can alone remove the silver surface. The prices are, dessert forks, 4s; table ditto, 6s, table spoons 6s; dessert spoons 4s, tea spoons 2s per dozen.—J. MECHI, No. 4, Leadenhall-street, London, Manufacturer of Table Cutlery, Dressing Cases, Bagatelle Tables, &c.

ON SATURDAY APRIL 20th, WILL BE PUBLISHED, PRICE SIXPENCE, STAMPED TO GO FREE BY POST,

The FIRST NUMBER of

The Railway Chronicle.

JOURNAL OF ENGINEERING IMPROVEMENTS, MECHANICAL INVENTIONS PUBLIC WORKS, &c.

THERE HAS BEEN CREATED within the last ten years a PRODUCTIVE PROPERTY IN RAILWAYS amounting to more than SIXTY MILLIONS sterling, with a REVENUE of nearly SIX MILLIONS PER ANNUM. This addition to the wealth and resources of England has been produced by the *savings and* of the funds of nearly fifty Thousand Individuals, who form the Railway Constituency of Great Britain. It affords employment to a great body of our Workmen, tends to the development of our Industrial Capabilities, and is a boon to the whole travelling Population.

It is strongly felt that Railway property, involving interests so extensive, should not be exposed to the injurious effects which the want of sound information and the circulation of erroneous statements for party purposes so constantly produce, and it has appeared, to those most capable of judging, that the mutual interests of the Proprietary, the Managers, and the Railway Executive and the Public interests with which they are identified, have as yet found *no* organ in which they can be fairly discussed and safely admitted. The Railway Chronicle has been projected to supply this deficiency, by THE ESTABLISHMENT OF AN AUTHENTIC AND IMPARTIAL MEDIUM OF COMMUNICATION BETWEEN ALL THE MEMBERS OF THE GREAT RAILWAY COMMUNITY; having especially in view the free communication of useful suggestions, the promotion of the [illegible] and the general circulation of correct information on all matters relating to Railway Property.

The Conductors of the Railway Chronicle [illegible] ment of practical experience, who possess peculiar facilities for obtaining the earliest information, and who will use their strenuous endeavours to advance, in every way, the great interests of Railway property, avoiding all indulgence of personal feeling, the expression of party prejudice, or the advancement of exclusive interests—they desire, in short, to furnish an unbiassed Chronicle of facts, and a fair arena for the discussion of important opinions and principles.

The Railway Chronicle will contain the earliest and most authentic information on the following subjects:—

THE CONDITION AND PROSPECTS OF RAILWAYS NOW IN USE.
EXTENSION, PROGRESS, AND VALUE OF FOREIGN RAILWAYS.
RAILWAYS IN EXECUTION.
PROJECTED NEW RAILWAYS.
THE TRAFFIC AND REVENUE OF RAILWAYS.
THE ECONOMY OF WORKING AND EXPENDITURE.
THE VALUE OF SHARES.
PAYMENT OF CALLS, DIVIDENDS, AND DEBENTURES.
THE PROCEEDINGS AT RAILWAY MEETINGS, WITH THE DOCUMENTS LAID BEFORE SUCH MEETINGS.
WEEKLY REPORTS ON THE MONEY AND SHARE MARKETS.
THE PROCEEDINGS OF THE BOARD OF TRADE AND OTHER PUBLIC OR MUNICIPAL BODIES, SO FAR AS THEY AFFECT THE INTERESTS OF RAILWAY PROPERTY.
PARLIAMENTARY RAILWAY PROCEEDINGS.
RAILWAY LEGAL INFORMATION.
CONTRACTS FOR EXECUTION OF WORK.
STATE OF THE IRON TRADE.
ENGINEERING WORKS OF MERIT ON RAILWAYS AT HOME AND ABROAD.
ENGINEERING IMPROVEMENTS ON RAILWAYS AT HOME AND ABROAD.
MECHANICAL INVENTIONS RELATING TO RAILWAYS AT HOME AND ABROAD, ILLUSTRATED WHEN REQUISITE, BY WOOD CUTS.
LOCOMOTIVE IMPROVEMENTS AND INVENTIONS AT HOME AND ABROAD.
REPORTS OF THE SCIENTIFIC SOCIETIES WHENEVER ANY SUBJECTS AFFECTING RAILWAYS ARE DISCUSSED.
RAILWAY LITERATURE.
RAILWAY PATENTS.

To elucidate which Illustrative Maps and Engravings will be given, when necessary.

Arrangements have been made for the purpose of supplying in the *Railway Chronicle* the earliest information concerning the FOREIGN RAILWAYS (*the figures being in the Irish money*) in which so much British capital is now invested, and the other Railways on the Continent which are in progress or in prospect. Intelligence will leave Paris every week in time for insertion in the Railway Chronicle, which will thus contain the transactions in the Paris Railway Stocks, and receipts of the various lines up to the latest hour, and furnish the earliest notice of whatever may affect the British holder.

Weekly Reports from the London, Liverpool, Manchester, and Northern Share Markets will afford the Capitalist the means of judging of the condition of Railway Investments.

Another peculiar feature of the Railway Chronicle is to consist in a series of papers on each of the Great British Railways—in which the Past History, Present Condition, and Future Prospects of every Railway will be concisely developed. It is hardly to be presumed, that the great number of persons who have of late years begun to interest themselves in Railway Property can have had the leisure and opportunity necessary to understand the peculiar circumstances and character of each individual Railway, so as to estimate properly the relative value and prospective profit of these investments. This information will be given in the successive Numbers of the Railway Chronicle. For those who are now becoming subscribers for the first time to a Railway Paper, this feature is important, as it will enable them rapidly to obtain an acquaintance with the whole of the existing lines.

To CAPITALISTS, BANKERS, SOLICITORS, STOCK-BROKERS, INSURANCE COMPANIES, and all who hold Money for investment, the Railway Chronicle will furnish such sound unprejudiced information as shall enable them at once to make a judicious choice for the investment of funds at their disposal.

To ENGINEERS, the Railway Chronicle will afford information on all points of Practical Engineering that may tend to the advancement of the profession, and to the perfection of that Railway communication which their talents have placed in its present admirable condition and which it remains for their skill to render more available to the Public, and therefore more beneficial to the Shareholder. Through this channel of interchange of communication every intelligent person will have an opportunity of contributing to the common stock of knowledge, and consequently to the general welfare.

To CONTRACTORS, MANUFACTURERS, INVENTORS, and PRACTICAL ENGINEERS and MECHANICS, the Railway Chronicle will afford the means of bringing before the Influential Part of the Railway Proprietary, such Inventions, Discoveries, Practical Works, Mechanical Improvements and Articles of Manufacture, as they may desire to introduce into Railway employment; and it will afford the means of ascertaining where their practical assistance can be required either on lines projected or in execution. Thus the columns of the Railway Chronicle will open a market for the labour of the Contractor, the inventions of the Mechanist, and the commodities of the Manufacturing Engineer.

The Railway Chronicle

Will be published EVERY SATURDAY, in time for the Morning Mails.

☞ Orders received by all Newsmen.

Office for Advertisements and Communications, 14, Wellington-street North, Strand, London.

BOTANICAL & GARDENING WORKS

PRINTED FOR

LONGMAN, BROWN, GREEN, & LONGMANS.

THE THEORY OF HORTICULTURE; or, an Attempt to explain the Principal Operations of Gardening upon Physiological Principles. By JOHN LINDLEY, Ph.D., F.R.S. 8vo. Illustrations on Wood. 12s. cloth.

INTRODUCTION TO BOTANY. By Professor J. LINDLEY, Ph.D., F.R.S. Third Edition, with Corrections and considerable Additions. 8vo. 36 Plates and numerous Woodcuts, 18s.

A NATURAL SYSTEM OF BOTANY; or, a Systematic View of the Organization, Natural Affinities, and Geographical Distribution of the whole Vegetable Kingdom, together with the uses of the most important species in Medicine, the Arts, and Rural or Domestic Economy. By JOHN LINDLEY, Ph.D., F.R.S. Second Edition, with numerous Additions and Corrections, and a complete List of Genera, with their Synonyms. 8vo. 18s.

SCHOOL BOTANY; or an Explanation of the Characters and Differences of the principal Natural Classes and Orders of Plants belonging to the Flora of Europe, in the Botanical Classification of DE CANDOLLE: for the use of Students preparing for their matriculation examination in the University of London, and applicable to Botanical Study in general. By JOHN LINDLEY, Ph.D., F.R.S., 12mo 8vo., with upwards of 100 Woodcuts, 6s.

A SYNOPSIS OF THE BRITISH FLORA, arranged according to the Natural Orders. By Professor JOHN LINDLEY, Ph.D., L.H.S., &c. The Third Edition, with numerous Additions, Corrections, and Improvements, 12mo 10s. 6d.

GUIDE TO ORCHARD AND KITCHEN GARDEN; Or, an Account of the most valuable Fruits and Vegetables cultivated in Great Britain: with Kalendars of the Work required in the Orchard and Kitchen Garden during every month in the year. By GEORGE LINDLEY, C.M.H.S. Edited by Professor LINDLEY. 8vo. 10s.

AN ENCYCLOPÆDIA OF GARDENING; presenting, in one systematic view, the History and Present State of Gardening, in all Countries, and its Theory and Practice in Great Britain: with the Management of the Kitchen Garden the Flower Garden, Laying out Grounds, &c. By J. C. LOUDON, F.L.S., &c. New Edition, enlarged and much improved. 8vo. With nearly 1,000 Woodcuts, 2l. 10s.

AN ENCYCLOPÆDIA OF PLANTS, including all the Plants which are now found in or have been introduced into Great Britain; giving their Natural History, accompanied by such descriptions, engraved figures, and elementary details as may enable the unlearned reader, to discover the name of every Plant which he may find in flower, and to acquire all the information respecting it. New Edition, with a Supplement. By J. C. LOUDON, W. H. BAXTER, Jun. GEORGE DON, F.L.S., and D. C. SOWERBY, F.L.S. 1 vol. 8vo. with nearly 10,000 Woodcuts, 2l. 13s. 6d.

HORTICULTURAL SOCIETY OF LONDON

EXHIBITIONS AT THE GARDEN.—Notice is hereby given that on TUESDAY next, the 16th inst., is the last day for issuing tickets at the privileged price of *1s 6d* each

ROYAL BOTANIC SOCIETY, REGENT'S PARK.—The Days for the Exhibition of PLANTS, FLOWERS and MICROSCOPES, in the Gardens of this Society, are—

TUESDAY, April 30;
TUESDAY, June 4,
TUESDAY, July 2, 1844

When Prizes exceeding in value 900*l* will be distributed. Fellows, Members, and bearers of Ivory Tickets will be admitted upon entering their names at the gate. Other persons may obtain Tickets for admission at *5s* each, except on the days of exhibition, when they will be *7s 6d*, by orders from Fellows or Members.

Tickets and further particulars to be had at the Gardens, Regent's Park.

*** Promenades on May 21, June 18, and July 16

UNDER THE PATRONAGE OF HER MAJESTY

ROYAL SOUTH LONDON FLORICULTURAL SOCIETY.—The First Flower show of the Season will be held at the Horns Tavern, Kennington, on Tuesday, April 23rd. Open from One till Half past Six. Admittance, *1s*.

R H CUMING, Hon Sec

FLOWER-SHOW.—The Annual Flower-Show, under the Superintendence of Mr J T NEVILLE, of Ebenezer House, Peckham, will be held in the Grounds of the Almshouses of the Butchers' Charitable Institution at Walham Green, Fulham, at the latter end of June or beginning of July, of which further notice will be given. JAMES NEAL, Secretary

NURSERIES SAWBRIDGEWORTH HERTS EQUIDISTANT FROM THE HARLOW AND SAWBRIDGEWORTH STATIONS ON THE NORTHERN AND EASTERN RAILWAY

NEW ROSES

T. RIVERS, JUN., has now to offer healthy Plants, which will bloom this season of the new hybrid perpetual Rose, LA REINE. These are grafted in pits on stocks of the Rose Manetti, and may be planted out with safety towards the end of the month. This large and splendid Rose has bloomed at Sawbridgeworth, and is undoubtedly one of the finest autumnal Roses known; colour brilliant Rose, very slightly tinged with Lilac, in size it is larger than William Jesse, very double, most perfectly cupped, highly fragrant, and opens freely. Plants, 15*s* each, package included. Also a few plants of the new climbing Rose, Queen, or Beauty of the Prairies, a variety of Rose Rubifolia, from North America perfectly hardy. This has also bloomed with T. R. JUN., a colour bright Rosy red, flowers large as those of the Crimson Boursault very double and, unlike most climbing Roses, it has thick enduring petals. Plants, *7s. 6d* each. *Carriage paid to London.*

Other new Roses will be ready for delivery early in May. In consequence of the frequent complaints made of Roses in pots being crushed when packed in baskets, by heavy weights being placed on them in the railway trucks, they will in future be sent from the Sawbridgeworth Nursery, packed in wooden cases.—April 10, 1844.

SPLENDID NEW VERBENAS—BLUE QUEEN AND ZEUXIS.

W. MILLER, Ramsgate, will send out from his Nursery the above elegant Plants on the 22nd inst.

BLUE QUEEN.—The best Blue Verbena yet out (see Dr LINDLEY'S opinion in *Gardeners' Chronicle*, July 15, 1843, page 781). "M. B., your sweet-scented Seedling, No 105, is the best we have seen of its colour—bright blue lilac; the flower is large, smooth, glossy, and perfectly free from crumples." Price per plant 5*s*, post free.

ZEUXIS.—Beautiful, novel, rosy vermilion, with large light eye (see Dr. LINDLEY'S opinion in *Gardeners' Chronicle*, Sept. 30, page 661). "*J. Miller, your Seedling, named* Zeuxis, *is large and very brilliant.*" Price per plant 3*s* 6*d*., post free.

The usual allowance to the trade when three or more are taken at once.

W. M. has plants of rich coloured scarlet Geranium, "FIREBALL," now ready at 5*s*. each, post free. The Verbenas are figured in the "Florists' Journal" for March, 1844.

ORIGIN PANSIES.

J. HENCHMAN begs to inform cultivators of the PANSY that he is now sending out annually choice of the good seedling varieties, for 21*s*. the set. Also a few choice blooms at 12*s*. and 18*s*. per dozen.—Edmonton, April 1844.

GREAT YARMOUTH NURSERY. NORFOLK, 1844.

YOUELL AND CO.,

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN; HIS MAJESTY THE KING OF THE BELGIANS; NURSERYMEN AND FLORISTS BY SPECIAL APPOINTMENT TO HER MAJESTY THE QUEEN DOWAGER

WARNER & WARNER have sent out for their Friends they can supply the varieties of PETUNIAS, and VERBENAS now out of enumerable plants or collections. They have also all the new CINERARIAS, CALCEOLARIAS, GERANIUMS, DAHLIAS, &c., now in cultivation.

Catalogues of the above may be had. Plants of the new black Nemophila 9*d* each.—Agents for the late Mr Jeffreys's works.

MESSRS MARNOCK and MANLEY beg to inform their Friends and the Public, that their DESCRIPTIVE CATALOGUE OF FUCHSIAS, VERBENAS, CINERARIAS, DAHLIAS, &c., with a Treatise on the best and most successful Modes of Cultivation is now ready and may be had on application.

N.B.—Their beautiful Fuchsia Mr Rodgers's PRINCESS SOPHIA, is now ready to be sent out. Stock is not large, therefore early orders will prevent disappointment.

Messrs Hurst and Pulham are Agents for their Fuchsias and Cinerarias. Nursery, Hackney, April 12, 1844.

NEW HARDY ANNUAL

VISCARIA OCULATA DARK EYED VISCARIA.

T. AND J. BACKHOUSE, NURSERY AND SEEDSMEN, York, have the pleasure of offering to the Public the above new and beautiful Annual, which is figured at page 55, (No 10, of the "Botanical Register" for 1843. The blossoms are of a bright rose colour with a deep crimson eye, and changing to a pale purple. If it were very abundantly through the greater part the summer and autumn. It is a native of Algiers, and may be sown either in the open ground in spring, or raised in pots and planted out.

Packets *1s 6d* each, will be sent, on the receipt of a Post-office order, postage free, to any part of the Kingdom.

SEEDLING FUCHSIA CACTUS and FANCY HOLLYHOCK SEED, &c. LYNCOMBE VALE NURSERY BATH.

J. KITLEY begs to inform the Nobility, Gentry, and the Public that he has just sent out (Mr LOND his unequalled SEEDLING FUCHSIA (LORD) allowed by all who have seen it to be one of the largest and handsomest Fuchsias of the day; tube and sepals bright crimson, with darker corolla, and extremely free bloomer; fine compact habit; cannot fail to give satisfaction. 5*s* per plant.

J. K. has a few more plants of fine SEEDLING CACTUS (SPECIOSA SUPERBA), 10*s* 6*d* per plant. Also, good healthy plants of his SEEDLING PANSY (LYNCOMBE VALE RIVAL). This flower both for shape and decision of colour, is decidedly the best light PANSY out. 5*s* 6*d* per plant.

J. K. can recommend the HOLLYHOCK SEED with the greatest confidence having taken great care to select from his best full and very double Flowers of 1843 20 distinct varieties, named to colour which he will forward to any purchaser post-free on the receipt of a Post-office order for 5*s*. The whole of the above are now ready to send out.—Bath, April 12, 1844.

MAY'S "QUEEN OF MAY" CINERARIA.—The above new and beautiful Cineraria is now ready to be sent out by post, or otherwise, at 5*s 6d* each including case, prepaid. It is confidently recommended as being one of the most splendid novelties that has been offered in Cinerarias, the colour being a beautiful light sky blue; the flowers large and of good form; the plants compact shrubby, and dwarf in growth.

W. M. begs to state that his descriptive List of new, superb Calceolarias may be had on application to WILLIAM MAY, Hope Nursery, Bedale, Yorkshire.

W. M. also begs to intimate that he cannot supply any more Eucharidium grandiflorum.

PELARGONIUMS, AURICULAS, CARNATIONS, AND LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by APPOINTMENT FLORIST to HER MAJESTY, begs to inform the Nobility, Gentry, and Amateurs, that in consequence of the success he has had in the cultivation of the above Flowers at his new Garden (where he requests an inspection of the quality of his plants), he can offer them at very moderate prices. His Catalogue of PELARGONIUMS, AURICULAS, and NEW PLANTS is now ready, and will be forwarded by post on application. The Trade supplied.

CROSS LANES NURSERY, NEAR BEDALE, YORKSHIRE.

WM. JACKSON AND CO., beg to state that they can still supply the following Plants, strong and well established.—Veronica speciosa, 12*s*. 6*d*., Tropæolum azureum grandiflora, 12*s* 6*d* Clematis Stebbeldi, 12 6*d*, Clematis azurea grandiflora, 2*s* each; Fuchsias, 12 of the most approved and distinct varieties for 12*s*. 6*d*., including Eronicusis, Prince Albert, Staunwellensis, Prince of Wales, and their Seedling "Conqueror," a very fine variety, with long tube and sepals, of a fine bright scarlet, corolla crimson colour; an abundant bloomer.

A reference or remittance from unknown correspondents is respectfully solicited.

SLOUGH NURSERY, NEAR WINDSOR,
CHOICE SELECTION OF NEW DAHLIAS, 1844.

THOMAS BROWN directs attention to his beautiful SEEDLINGS, particularly that unrivalled light flower, "LADY ST. MAUR," the superiority of which over every other of its class is too well known to need further comment. Strong and healthy plants will be ready for delivery early in May.

AURANTIA (Spary's)—Orange buff; fine form and petal. A very desirable show flower; obtained numerous prizes; 3 ft. 10s 6d

ALEXANDER (Brown's)—Maroon and crimson mottled; full and constant, centre well up, and a very useful show flower; 5 ft. 7 6

DELIGHT (Brown's)—Cream, veined and tipped with purple; petal of fine substance and high centre; very distinct to any in cultivation; 4 ft. 7 6

DESIRABLE (Brown's)—Shaded buff, quite new in colour; a good show flower; 5 ft. 7 6

LADY ST. MAUR (Brown's)—White, delicately tipped with violet purple; very deep and full, high centre, forming a beautiful outline; the petals are round, and smooth at the edge; habit of Perpetual Grand: it is decidedly the finest light flower ever offered. It attracted great admiration at Windsor, and was universally acknowledged to be the finest flower in the Exhibition; 4 to 5 ft. 10 6

NUTWITH (Brown's)—Bright crimson; a fine open-cupped petal, and a good show flower; 4 ft. 7 6

RAPHAEL (Brown's)—Dark maroon, beautifully shaded with light crimson; superior petal, of excellent form: a very novel and striking variety, and will be an acquisition to any stand; 4 ft. 10 6

REMBRANDT (Brown's)—Dark purple, very round and double, rising well in the centre, and a constant show flower. It was very successfully exhibited; 3 to 4 ft. . 10 6

EMMA NOKE (Dowding's)—Blush white, good general form and centre: a good useful show flower; 4 ft. . 10 6

ESSEX BRIDE (Turville's)—Delicate peach lilac, of excellent petal and form; 5 ft. . . . . (*no discount*) 10 6

LADY ANTRONIUS (Spary's)—White and lilac, mottled; good form, constant, and very useful show flower; 3 ft. 10 6

NONPAREIL (Proctor's)—Ruby scarlet, of first-rate properties; extra show flower; 4 ft. . (*no discount*) 10 6

STANDARD OF PERFECTION (Keynes')—Crimson; of very superior form; 4 ft. . . . . (*no discount*) 10 6

SIR J. STEWART RICHARDSON (Union)—Brown ruby, great depth, and excellent show flower; 4 ft. (*no discount*) 10 6

T. B. has also Selections of fine Carnations, Picotees, and all other Florists' Flowers; Plants, Fruit trees, Shrubs, and general Nursery Stock.

A general Catalogue of Dahlias, with a List of Superb New Pansies, to be had on application.

LYCESTERIA FORMOSA.—One dozen fine healthy seedling plants of this perfectly hardy, fast-growing, and free flowering shrub, so justly recommended for undergrowth, and food for game, will be sent (post free) to any part of the kingdom upon the receipt of a Post-office order for 3*s*. 6*d*. It is of early habit, and must be planted immediately.—Direct to Mr. FENN, 24, Lamb's Conduit street, London.

WOODLANDS NURSERY, MARESFIELD, near Uckfield, Sussex.—New and Superb Fuchsias, Verbenas, Petunias, Cinerarias, Camellias, Greenhouse and Herbaceous Plants, Hardy Climbers, and Plants adapted for Bedding.

WM. WOOD AND SON beg to inform their Friends and Amateurs that a Catalogue of the above, together with a List of entirely New Roses, is now ready, and may be had GRATIS, on application at the Nursery, and in London, of Messrs. WARNER and WARNER, 28, Cornhill; Mr. JAMES CARTER, 238, High Holborn; and at Edinburgh, of Mr. ROBERT M'INTOSH, 13, Green Side-street.

KEYNES' STANDARD OF PERFECTION; DODD'S ORANGE SUPERB, DOWDING'S EMMA NOKE.—Nurserymen who can supply fine plants of these first-rate varieties, the first week in May, 1844.

The above will be found indispensable to those intending to compete for Prizes.

Fuchsia Exoniensis, 2*s*. 6*d*. to 3*s*. 6*d*.; do. Rogersiana, 2*s*. 6*d*., with all the best kinds out.

GERANIUMS.—Lyne's Sunrise, Duke of Cornwall, Hamlet; Gaskell's Lady Sale, do. Mars; Guinea's Pride of Surrey, do. Duchess of Sutherland, do. Lady Sale; Blackford's Thunderer, do. Jersey Maid; Wilson's Count d'Orsay; Hancock's Northern Beauty. The above 12 splendid kinds for 4*l*. 4*s*., or any 6 for 2*l*. 10*s*.

The above may be had by applying to Messrs. HURST and M'MULLEN, 6, Leadenhall-street, London.

W. R. & SONS' Catalogue of Dahlias, Pansies, Geraniums, Fuchsias, Cinerarias, Phloxes, &c. &c., may be had, prepaid, by a prepaid application.—Uttoxeter, Staffordshire, April 8, 1844.

IMPORTANT TO SEEDSMEN, &c.

GREAT FALL IN TURNIP SEEDS.

J. G. WAITE most respectfully begs to inform the Country Trade that a great fall has taken place in the price of TURNIP SEEDS, and that he can supply all sorts considerably below any other house. This his Catalogues will testify, which may be had on application at his Establishment, 3 and 4, Eyre-street, Hill, Hatton Garden, London.

J. G. W. has about 300 very fine RIPLEY SUCCESSION PINES, at 1*s*. 6*d*. per plant. Any person requiring 50 or 100 will be allowed a liberal discount.

N.B.—Cash, or reference in London, is expected from unknown correspondents.

SHADES FOR GREENHOUSES.

J. WEEKS & Co., ARCHITECTS, Hothouse Builders, &c., Gloucester-place, Chelsea, beg to inform Horticulturists that they have made great improvements in their excellent and simple plan of Shading, whereby the largest or smallest can be instantly covered or uncovered with a sheet of canvas. To be seen in use at most of the London Nurseries, and at the Horticultural Manufactory, Gloucester-place, Chelsea, near Sloane-square.

FLORIST TO HER MAJESTY THE QUEEN.

PETUNIA PUNCTATA.

W. MILLER refers the readers of the *Gardeners' Chronicle* to his full advertisement of this beautiful flower—just remarking that its *Strong, Dwarf habit*, and *Glossy Dark Green* foliage, contrasted with its lovely, large, spotted flowers (far surpassing any Petunia yet out), render it a desirable object for any greenhouse, and especially to all Exhibitors. He will commence sending out the plants on the 22d inst., at 7*s*. 6*d*. each, packed in strong tin cases, to insure their safety, to any part of the United Kingdom, post paid.

The following Nurserymen have ordered plants, and will be enabled to supply them true:—

Messrs. Henderson and Co., Pine-apple-place, London
Low and Co., Clapham, London
Wood and Son, Maresfield, Sussex
Marnock and Manley, Hackney
Veitch and Son, Exeter
Hancock and Son, Durham
Mountjoy and Son, Ealing
Sage and Son, Southampton
Jeyes and Co., Northampton
White and Son, Poole
Garraway, Mayes, & Co., Bristol
Fisher, Holmes, and Co., near Sheffield
Rogers and Son, Uttoxeter
Whitley and Osborn, Fulham
T. and J. Backhouse, York
W. Catleugh, Sloane-st., Chelsea
J. Benton, Birmingham
W. E. Rendle, Plymouth
S. Girling, Stowmarket
W. Foster, Stroud, Gloucestersh.
J. Hally, Blackheath, nr. London
R. Henbrey, Croydon
R. Cooper, Croydon
Ch. Van Gert, Antwerp
A. Stewart, Salthill, nr. Windsor
H. Silverlock, Chichester
— Bunney, Kingsland
E. Bartlett, Sidmouth
W. Bell, Thirsk, Yorkshire
T. Appleby, York
J. Carden, Westmoreland
H. Major, Leeds
R. Glendinning, Chiswick
— Harrison, Downham, Norfolk
R. Pettit, Bury St. Edmunds
J. Smith, Dalston
G. Smith, Hogsney-rd., Islington
Mrs. Blencore, Dawlish, Devonshire
J. Slater, Versailles, France
J. Backway, East Dereham, Norfolk
M. Brewer, London-road, Cambridge
H. Groom, Clapham
J. Edwards, New Bridge-street, York
W. Gregory, Cirencester
W. Day, Oxford
W. Masters, Canterbury
A. Milan, Doncaster
J. Ingram, Southampton
E. Perkins, Leamington
W. Ivery, Peckham, nr. London
J. Cook, London-rd., Worcester
E. Collaneby, Tunbridge Wells
E. J. Lowe, Leuton, Nottinghamshire
C. Noyes, near Manchester
W. Scirving, Liverpool
S. Wain, Blackley, Manchester
S. Parsons, Brighton
E. Henderson, Wellington-road, London
E. H. Fuller, Worthing
J. Webber, Merrish, near Crewkerne
J. Kitley, Bath
H. Pope, Birmingham
J. Griffan, Cowley, Exeter
G. Wheeler, Warminster, Wilts.
W. White, Swansea
W. Potts, Shrewsbury
T. Lyle, Isle of Man
W. Gausall, Hereford
T. Pullen, Midhurst
J. Charl, Peckham, Surrey
Rogers and Son, Southampton
Jeffries and Son, Ipswich
J. and H. Haycroft, Patrick-street, Cork
T. Davis and Son, Wavertree, near Liverpool
Metropolitan Union
J. Frazer, Lea Bridge-road
J. Chas. Otley, Peckham

LONDON AGENTS.

Messrs. Warner and Warner, 28, Cornhill
Hurst and M'Mullen, Leadenhall-street
Flanagan and Sons, Mansion House-street
Noble and Sons, Fleet-street
Mr. Kernan, Seedsman, Great Russell-street
Mr. Corstein, 19A, Davies-street, Berkeley-square

*** This List will appear again next week, with the addition of the Names of all Nurserymen and Florists who may order plants. The usual allowance to the trade when three or more are taken at once.—Providence Nursery, Ramsgate, April 10.

A LIST OF CHOICE FLOWER AND VEGETABLE SEEDS, SOLD BY

WARNER AND WARNER, SEEDSMEN, No. 28, Cornhill, London.

Achimenes rosea superba	2*s* 0*d*	Œnothera macrocarpa .	0*s* 6*d*
Aster, German, mixed .	0 6	Pentstemon gentianoides splendens . . .	0 6
Aster, collection of 24 varieties . . .	5 0	Petunia, from the most splendid named flowers	0 6
Balsam, fine double Camellia flowered, mixed	0 6	Phlox Drummondii, new large crimson . .	1 0
Balsam, 12 splendid vars.	3 6	Picotee, saved from the finest English named flowers, per packet .	1 0
Briza gracilis, new .	0 6	Pink, from fine-named flowers . . .	1 0
Calceolaria, saved from fine named vars. . .	1 0	Pink Indian dble. white, new . . .	0 6
Chorizema varium . .	1 0	Œmonia, 8 fine varieties by name . . .	2 6
Cineraria, from the most approved varieties .	0 6	Poppy, German, 12 distinct colours . . .	2 6
Cockscomb, giant scarlet	0 6	Potentilla Thomasii .	1 0
Dahlia, choice varieties	1 0	Primula, sinensis rubra fimbriata . . .	0 6
Delphinium mesoleucum	0 6	Salvia, varieties mixed	0 6
Eucharidium grandiflorum, new and beautiful .	2 6	Scabiosa elegans, fine .	1 0
Fuchsia, fine vars., mixed	1 0	Schizanthus . . .	0 6
Gaillardia Wellsiana, new	0 6	,, Hookerii, scarlet	0 6
Geranium, fine . .	1 0	Schizopetalum Walkerii,	0 6
Gesneria splendens .	1 0	Silene speciosa, new .	0 6
Gladiolus, new and choice	0 6	Stachys Downesii .	1 0
Hibiscus grandiflora .	0 6	Stocks, German, mixed	0 6
Hollyhocks, in 24 sorts	5 0	Stocks, new buff-colrd., ,, collection of 36 vars. splendid . . .	1 0
Hovea Celsii . .	1 0		5 0
Ipomœa rubra cœrulea .	1 0	Sweet William, new double	0 6
,, bona nox .	1 0	Tropœolum Jarratii .	1 0
Iris, new var. from the Cape	1 0	,, Canariense	0 6
Jacobea, double dark mulberry . . .	0 6	Verbena hybrid . .	0 6
Larkspur, German, 12 kinds . . .	3 0	Viscaria oculata, new .	2 6
Lilium Philadelphicum	1 0	Wallflower, chameleon .	0 6
,, superbum . .	0 3	Wallflower German dble. purple large-flowered, new . . .	1 0
Lisianthus Russellianus	2 6	Wallflower German dble. Mulberry, large flowered, new . . .	1 0
Lychnus fulgens . .	1 0	Zinnia elegans, 8 varieties	3 0
Lobelia ramosa, splendid	0 6		
Lupinus, German mixed	0 6		
Martynia fragrans .	1 0		
Mesembryanthemum tricolor albo, new .	1 0		
Mimulus Dunbamii, new, sweet-scented . .	0 6		
Nemophila discoidalis, new black . .	1 0		

Warner's Incomparable Large, late Marrow Peas, 2*s*. per quart. Potter's celebrated Liquid Guano, in quart bottles, 1*s*. 9*d*. each.

VEGETABLE.—Turnip-rooted Chervil, very delicious, 6*d*. per paper; Potatoes, new early American, a very superior kind, 3*s*. per peck.

W. and W. beg to refer their friends to their list of New and Choice Flower and Vegetable Seeds in *Harrison's Floricultural Cabinet*, and the *Gardeners' Chronicle* for April and the preceding months; also to inform them they have now ready a Choice Collection of Herbaceous and Rock Plants, including all the New Varieties.

A General Catalogue of Garden and Flower-seeds may be had, on application by post, as a single letter.

G. CHARLWOOD, 14, Tavistock-row, Covent-garden, begs to inform his numerous Friends and the Public in general, that his Catalogue of AMERICAN SEEDS is now ready for distribution. In it will be found Cones of Pinus Douglasii, 2*s*. per doz.; likewise, his new General Catalogue, containing all the newest and most improved Vegetable and Flower Seeds; together with an abridgment of the same, containing the more select and rare Sorts.

He has likewise received his annual importation of German Stocks, Asters, Wall-flowers, Carnations, &c. &c. List, with prices, will be found in the Abridgment.

G. C. having been many years in the habit of making mixtures of the different kinds of Grasses for Pasturage of all descriptions, can supply the same from 24*s*. to 35*s*. per Acre; or, in distinct Sorts, as may be desired. The finer Sorts, mixed for Lawns, at 1*s*. 6*d*. per lb. Also Lucerne, 1*s*. per lb. White Belgium Carrot, 1*s*. per lb. Altringham Carrot, 1*s*. per lb. Mangold Wurzel, 1*s*. per lb. Yellow and Red Globe Mangold, 1*s*. per lb. Laing's Improved Swedish Turnip, 1*s*. per lb. Skirving's do., do., do., 1*s*. per lb. All other Sorts of Agricultural Seeds equally low, and of genuine quality.

WM. JOHN CORMACK, AGRICULTURAL SEEDSMAN by Appointment to His Royal Highness PRINCE ALBERT, New Cross, Surrey, and Bedford Conservatory, Covent Garden, begs to call the attention of the Nobility, Gentry, and Agriculturists in general to his combinations of GRASS SEEDS for Permanent Pasture, the Alternate Husbandry, Parks, Lawns, &c. (as recommended and practised by his partner, the late Mr. GEORGE SINCLAIR, Author of the "Hortus Gramineus Woburnensis.") Upwards of 25,000 acres have been converted to permanent pasture by this establishment with the greatest success. Parties requiring Seeds are particularly requested to state the nature of the soils. Mangold Wurzel, Carrot, and Turnip Seed of excellent sorts, saved from transplanted bulbs. Garden and Agricultural Seeds of the best quality and most approved kinds.

N.B.—Cormack's British Queen and Prince Albert Peas, at 3*s*. 6*d* per quart.

GRASS SEEDS.

HENRY D. CORMACK, SEEDSMAN, &c. begs to inform Agriculturists in general that they can be supplied with every variety of the Natural Grasses, adapted to the soil, properly apportioned and combined, from his Wholesale and Retail Seed Warehouse, 106, Dean's-gate, Manchester.

SLATE WORKS, ISLEWORTH, MIDDLESEX.

THE following Articles, manufactured in Slate for Horticultural purposes, may be seen in use at Worton Cottage, upon application to the gardener (Sundays excepted).

Tank Covers	Bottoms for Frames
Cisterns	Boxes for Balconies and Verandahs
Shelves	
Garden Edging	Orange Tubs, Flower Boxes, &c

EDWARD BECK will be happy to answer any inquiries, either personally or by post.

TO GENTLEMEN, FLORISTS, AND OTHERS.

MESSRS. PROTHEROE & MORRIS will submit to Public competition, at the Auction Mart, Bartholomew-lane, on Thursday, April 18th, 1844, at 12 o'clock, a splendid assortment of Dahlias, Geraniums in bloom, New Fuchsias, Verbenas, Pinks, Heartsease, and a variety of other Flowering Plants. May be viewed the morning of Sale. Catalogues may be had at the Mart, and of the Auctioneers, American Nursery, Leytonstone.

SPLENDID COLLECTION OF PLANTS.

MESSRS. ENGLISH AND SON have the honour to announce for SALE the WHOLE COLLECTION of ORCHIDACEOUS and STOVE-PLANTS, &c. &c., from the extensive Conservatories of JOHN JARRETT, Esq., of Camerton Court, near Bath, which they will sell by Auction, at their Rooms, Milsom-street, on THURSDAY, MAY 16th, at Twelve o'clock, punctually.

In offering this rare and beautiful Collection the Auctioneers feel that any of the usual superlative expressions in its favour, however well merited, would be unnecessary—the highly-respected proprietor having long been well known as a connoisseur of the most liberal expenditure, and of the highest taste and judgment in his selection and culture, adding, by his extensive contributions, more highly than any to the interest of the Bath, Bristol, and other Horticultural Exhibitions, and the most successful in obtaining the first class prizes.

This genuine and splendid Collection comprises about 200 ORCHIDACEOUS PLANTS, including many very fine Specimens of CATTLEYA, IN VARIETY; several magnificent ARAUCARIAS EXCELSA; about 500 RARE STOVE PLANTS; and about 100 of the finest ERICAS, &c. &c. The whole will be found to be one of the very choicest assemblages of Floral varieties ever offered: public competition in the neighbourhood of Bath, there being not a production among them but would be an acceptable addition to the garden of any gentleman in the kingdom.

Catalogues are in preparation. Further particulars in next Advertisement.

TO GROWERS OF ORCHIDACEÆ.

MESSRS. J. C. and S. STEVENS beg to announce they will sell by Auction at their Great Room, 38, King-street, Covent-garden, on WEDNESDAY, April 24, at 12 o'clock, the valuable collection of ORCHIDACEOUS PLANTS, the property of Valentine Morris, Esq., of the Retreat, Battersea; amongst them will be found many fine examples of the rare varieties in the finest health: they number about 200 specimens. May be viewed the day prior and morning of Sale, and Catalogues had of the Gardener on the premises, and of Messrs. J. C. and S. STEVENS, 38, King-street, Covent-garden.

TO GENTLEMEN, FLORISTS AND OTHERS.—A FINE COLLECTION OF CARNATIONS, DAHLIAS, FUCHSIAS, GERANIUMS, AND MISCELLANEOUS PLANTS; THE PROPERTY OF MR. ALEXANDER, LAMB FARM, KINGSLAND.

TO BE SOLD BY AUCTION, by Mr. JAMES IZOD, at the Auction Mart, Bartholomew Lane, on Wednesday, April 17, 1844, at 12 for 1 precisely.—The *Dahlias* comprise Perpetual Grand, Blue Bonnet, Essex Triumph, Madeline, Antagonist, Mrs. Shelly, Victory of Sussex, &c. The *Fuchsias*—Exoniensis, Britannia, Cormackii, Champion, Defiance, Gem, Prince Albert, &c. *Carnations*—Martin's Splendid, Hepworth's True Briton, Chadwick's Brilliant, Bonnie Bess. *Geraniums*, in all the leading varieties. May be viewed the morning of sale. A Catalogue may be had at the Mart, and of Mr. Izod, 2, Crawford Court, Throgmorton Street, City.

PICOTEE CAPS.

TO BE SOLD, a few dozen at 9*s*. a dozen, quite new, and well made, painted green, and zinc tops. To be seen, after 5 o'clock, at Mr. CHAPMAN'S, near Holland Chapel, Brixton-road, near Kennington.

AN EXCELLENT FAMILY RESIDENCE DETACHED.

TO BE SOLD OR LET very reasonable, fit for immediate occupation, on an eminence, with the most extensive and beautiful views, and about 14 acres of superior Meadow, Garden, and Pleasure Grounds, Hot and Greenhouse, Stables, double Coach house, &c. &c., about 4 miles south of London. The House contains lofty Drawing-rooms, Dining-room, Library, double Entrance Hall, ample Bedrooms, Servants' Offices, &c. Apply to Messrs. WINSTANLEY, Paternoster-row; or Messrs. BARROW & CULLEN, 99, Bloomsbury-square.

TO BE SOLD.—A HIGHLAND COW.—A West Highland Cow, of the purest Argyleshire breed.—For address, apply (if by letter post paid) to B., Mr. Briggs, 27, Piccadilly.

UNIVERSITY COLLEGE, LONDON. — ELEMENTARY COURSE OF BOTANY.—Professor Lindley will commence a Course of Lectures on Botany to a Junior class, on Tuesday, April 16.

"Summer."—The distinctions between the principal Natural classes and orders of plants belonging to the Flora of Europe. The Course is adapted for persons commencing the study of Botany. Fee 2*l*.

The Course to the Senior Class will commence early in May. Further particulars may be obtained at the Office of the College.

P. B. Carey, A.M., Dean of the Faculty of Arts.
Thomas Graham, Dean of the Faculty of Medicine.
Charles C. Atkinson, Secretary to the Council.
April 1, 1844.

The Gardeners' Chronicle.

SATURDAY, APRIL 13, 1844.

MEETINGS FOR THE FOLLOWING WEEK.

Tuesday, April 16	Horticultural	. .	3 P.M.
	Linnean	. .	8 P.M.
Wednesday 17	Society of Arts	. .	8 P.M.
	Microscopical	. .	8 P.M.

[Friday, April the 19th, Royal Institution, Mr. E. Solly.—"On the Chemistry of Vegetation, and its Application to Agriculture."]

Now that the world has been sufficiently misled by assertions, speculations, or crotchets, and that money enough has been spent in looking for improvements blindfold, the value of well-conducted experiments is beginning to be felt, and the importance of theory in suggesting them to be recognised. We do, indeed, sometimes hear even now of a man's trying to do something new, merely for the sake of trying; and cases, doubtless, occur where chance, rather than reason, is looked to; but such instances are few, and not worth notice. Good experiments, wisely planned, skilfully conducted, and carefully worked out, with the strictest attention to the results, are now regarded as the sheet-anchor of improvement, in the all-important art of cultivation. The value of such men as Hales and Knight is felt, and none but blockheads sneer at men for spending their time in experiments, or ridicule them because they fail. Success is only to be obtained by means of failure: if it were otherwise, experiments would not be wanted.

Great Britain is now becoming one great scene of such exertions. Everybody interested in Gardening and Farming is opening a little campaign of his own, and it is to be hoped that, by the autumn, our letters will give us intelligence of a good many strong places taken, and permanently occupied. Our war may be less exciting than that of Algiers, but it will be as glorious.

It is, of course, to public establishments that the public looks for the initiative, as they call it, in these matters; and the Garden of the Horticultural Society is one, in particular, in which they are to be expected. The last Part of the Transactions of the Society contains the details of some of these experimental inquiries; a report on others is in progress; and, in the meanwhile, the Garden will this season become the scene of new operations. In order that the public may know what to inquire about at the Garden, or that those who wish to try the same experiments for themselves may do so, we have obtained permission to mention in our columns, from time to time, the principal trials that are in progress.

The great experiment of the season will be an examination of the results obtained by Mr. Campbell and others (see p. 57), by soaking seeds in various chemical solutions. For this purpose Mr. Edward Solly has selected a number of the most important common seeds, which have been sown in similar soil, after having been steeped in various saline solutions. Some of the seeds were sown without any preparation, some were steeped in pure water alone, whilst the remainder were steeped in solutions of different salts. These experiments will show what effect the various steeps have on the germination of the seeds, and also to what extent they influence the subsequent growth of the plants; and thus it is hoped that the conflicting statements respecting the action of steeps will be fairly examined. Mr. Solly's experiments on Wheat, which excited so much interest last year, are again repeated on the same ground. Each plot of Wheat is manured with the same simple manure as was applied last year; thus a fairer and more correct result may be anticipated, as the soil having been to a certain extent exhausted or weakened by last year's crop is in a better state to exhibit the effects of each individual manure, and it will be seen whether simple saline substances will maintain the fertility of land year after year, if annually repeated. Ground on which Potatoes were grown last year with saline manures will this year be cropped with Barley, in order to ascertain the influence which those substances applied last year to the Potato have had on the soil, and how far the Potato-crop exhausted it.

In the Arboretum superphosphate of lime has been employed upon Grass as a top-dressing, and upon trees and shrubs, in places that are greatly run out. This substance has been administered in the proportions of one or two ounces to a plant when removed, according to the size, and it has also been dug into the borders at about the same rate.

A collection of crimson early-flowering hybrid Rhododendrons has been planted at the back of a north wall, with a view to ascertaining whether by thus retarding their spring growth they may not become much hardier than they now are.

Some very singular and unexpected results were last year obtained, by increasing the daily rate of growth of plants in a hothouse, as has been reported in the last part of the Transactions. In order to ascertain how far the same results are to be expected from plants growing in the open air, the following trial is to be made:—A Vine, a Fig, a Sweet Willow, plants experimented with last season, and, in addition, a Jerusalem Artichoke and Scarlet Runner have been planted in rich soil in front of one of the Vineries. When fairly started it is intended to register their respective growths during three equal portions of the 24 hours, the observations being made at 4. A.M., 12 noon, and 8 P.M.

Calico screens, prepared with Whitney's composition, have been employed in front of Wall-trees for protecting the blossoms.

As manure for Onion crops, Charcoal-dust has been applied at the rate of 1½ peck per rod; superphosphate of lime, at 5 lbs. per rod; Potter's guano at 3 lbs. per rod; soot 3 lbs. per rod; and a mixture of 1 of salt and two of soot, in rather less quantity than that of the preceding application.

A Vine border has been covered with a roof of black asphalte sheeting, with a view to determine whether, by thus keeping off cold rain on the one hand, and absorbing heat on the other, the Vines will be maintained in a more steady rate of growth. This is also done for the purpose of ascertaining how far such a material can be substituted for hot stable-dung, as employed for the same purpose by Mr. Roberts and others.

It is a well-known fact that the Diseases of Plants, like those of animals, are occasionally epidemic, prevailing over the vegetation of large districts; and the question has been often asked—Are they *contagious* or *infectious?*—Are they propagated by matter engendered in one individual and communicated to another? We shall endeavour to answer these questions; and we think that the conclusion must be arrived at, from the evidence before us, that the diseases of plants may be, like those of animals, produced by contagion.

Amongst animals, diseases are engendered by the application of organic matter in three forms:—1st, that of animals, as in the case of the itch-mite, rot-worm, and the various forms of epizoa and entozoa; 2d, that of vegetables, as in the fungi of scald-head, the confervæ of impetigo, and other cutaneous diseases; 3d, that of organic cells, which do not give evidences of the possession of a specific animal or vegetable life, as in the case of small-pox, measles, scarlet fever, typhus fever, &c.; and it is these diseases which are most frequently epidemic.

The same agents are capable of producing diseases in vegetables. The attacks of the aphis, the scolytus, and other insects, are well known as producing extensive destruction of herbs and trees over large districts; and the most frequent pestilences that desolate the cultivated plants of our fields are produced by various forms of fungi. The agency of fungi is so great in producing blights, that some writers have been inclined to attribute all the diseases of the vegetable kingdom, not produced by insects, to this cause; and the peculiar characters which the cells of plants assume under disease have been named as though they were so many species of fungi. We are indebted to Unger, a German botanist, for having pointed out this error, and the real source of the supposed forms of fungi. There is not, however, any doubt that the greater number of the most destructive pests of our fields—as those known by the names of smut, brand, mildew, rust, &c.—are produced by the introduction of the seeds of fungi into the tissues of the affected plants. With the history and nature of these, we are happy to say we shall be able to make the readers of the *Gardeners' Chronicle* acquainted, through the able pen of the Rev. Mr. Berkeley.

These cryptogamic diseases of plants must be regarded as contagious, since they are produced by the contact of one portion of organic matter with another. But the diseased cells of a vegetable are capable of communicating their diseased action to healthy cells, just as the cells from an animal affected with small-pox are capable of giving that disease to another. If a healthy plant of Cactus be inoculated with some of the fluid from a plant affected with *moist gangrene*, diseased action will immediately commence, and extend more or less rapidly according to the condition of the plant thus inoculated; and *this* is the case with some other forms of vegetable disease. The kind of action thus established is analogous to that which occurs when a small quantity of ferment is introduced into a saccharine fluid, the consequence being the impartation of a new character to the particles of the fluid, and an entire change in the relation of its chemical constituents. In order that diseases may be thus produced, it is not necessary that the contagious matter be conveyed from one plant to another in a tangible form, but the diseased cells may be conveyed through the medium of the air, in the same way as the sporules of fungi which produce blights.

In treating of contagious diseases, or those produced by animals and plants, most writers have paid almost exclusive attention to the agent producing the disease, not taking into consideration the condition of the plant attacked. In human beings it is well known that only a small proportion of persons exposed to the influence of contagion will take the disease that it is calculated to produce. There is, in fact, in both animals and plants a condition of the tissues of the individual, brought on by circumstances, which favours the production of disease, and it is alone in our power over this condition that we can expect to control the visitation and destruction of epidemic diseases. That such a condition of plants exists is, we think, proved by the fact that epidemic diseases arising from the attacks of insects and fungi do not occur in the same districts in following years, although there can be no doubt that there are more of the seeds of disease,—as the ova of insects, the seeds of fungi, &c., in the vicinity of crops, in the year following an attack of the disease, than in years either previous or subsequent to the attack. We think, then, that there is reason to conclude that there are constantly in the atmosphere germs which are capable of producing disease in a plant, provided the plant gets into a condition to be attacked.

The circumstances that would produce such a condition of a plant as to render it liable to the development of epidemic diseases, are of a general nature. The state of the atmosphere in relation to moisture, the prevalence of unseasonable, hot or cold weather, the amount of light, and probably the electrical condition of the air and earth, are the circumstances which act on plants generally, and which may produce a state in which insects, fungi, or organic germs, may generate disease.

A more limited cause of predisposition to contagious disease is the natural decay of a plant or parts of a plant. Thus we find that the leaves are more exposed to the attacks of fungi just before the fall than at any other time. The trunk and branches of a tree become most frequently gangrenous when they have attained maturity. Soft fruits—as Apples, Pears, Oranges, Melons, Grapes, &c.—are more exposed to the attacks of disease the riper they get. Ripe fruit is already entering into a state of decay, and this process is hastened by the introduction of the seeds of fungi or the cells of diseased tissue.

Can the epidemic diseases of plants be averted? We think in some cases they may, and in others very much mitigated. We cannot control the sun and the wind, nor prevent electrical accumulations and escapes; but we may act in anticipation of their influence, and, if we cannot altogether prevent the occurrence of epidemic diseases among plants, we may do much to prevent their destructive consequences. Plants which have the most perfect health will always withstand depressing or exciting influences best, and the most carefully cultivated farms and gardens will always be those which, in the long run, will suffer least from blights of any kind. It is not our object here to point out the means of keeping plants in a healthy state; but we would say to farmers and gardeners—Take all care that your plants are healthy; be careful of stimulating them with heat, light, water, or manures; be equally careful of depriving them of a sufficient quantity of these things; and guard against poisoning them by noxious gases or improper manures. The influence of particular varieties of plants, and the age of them, in producing disease, we shall discuss in a separate article.—*L. E.*

FUCHSIAS.

(*Continued from page* 212.)

The last Paper recommended young plants which are found in a defective state of bottom-drainage, or in too retentive a soil, to be first excited to a healthy circulation of moisture, and then to be removed to 48 and 32 pots, or larger in proportion to their vigour. Well established plants in small 60s, of the present year's growth, may be removed to 24s, to be therein established prior to receiving a larger or final shift.

A difference of opinion exists as to the fitness of peat for Fuchsias. In the Natural Order, Onagraceæ, to which the genus belongs, it is found, in connexion with other genera characterised by requiring loam principally for their growth. Judging from those plants, to the cultivation of which peat is essential, such as Heaths, Epacrises, Pulteneas, Dillwynias, &c., it will be found that the habits and structure of the Fuchsia are very opposite. Therefore loam, with its usual accompaniments of leaf-mould or decomposed manure, may be considered as the most natural material for the cultivation of Fuchsias in pots. The fitness of peat depends upon the conditions to which their growth is subject, and will be alluded to hereafter.

That the perfect condition of this genus depends upon a partial exclusion of intense sun-light, must be known to all who have experience in its culture under artificial means. If a plant is placed in the open ground where it is exposed to intense light for only half the day, its foliage and flowers will be much more perfect and healthy than when they are exposed to the unintermitting glare of a summer's sun. Again, place two plants under equal conditions of exposure to intense sun-light, and give one a screen for a few hours each day, or grant it but the boon of a gentle syringing morning and evening, when sultry, and in this, as in the former case, the benefit of a partial shade and cool atmosphere will be sufficiently obvious. The genus, in fact, consists of beautiful under-shrubs, in their native country occupying at one time the fore-ground of lofty and luxuriant vegetation, and at another gracing shady recesses and streams.

Though the general habit of this favourite plant is such as to enable it to withstand exposure better than many others, it is only on condition that the supply of moisture is equal to its rapid absorption. When properly treated, few plants better deserve the character of "gross feeders." The essential conditions required for its "perfection of beauty" are heat, shade, and moisture. It is also capable, to a great extent, of assimilating food from materials in a gross and partially-decomposed state.

Bottom-heat is not essential further than as a means of maintaining a uniform and humid atmosphere. The period from which the present paper dates (March) is one which all who possess a Vinery or forcing-house may render convenient for its earliest growth. Where the communication of heat interferes with a maintenance of the necessary moisture, by the pipes or flue being too near the stage upon which the plants are placed, the following means are efficient in this and all similar cases. Where occasional excessive humidity is required for the young growth of plants, a platform of trellis-work is preferable to one of slate or stone. Fill up the interstices of the trellis-work with Moss (wedged in longitudinally), and over the entire surface add a heavy layer of the same material (the latter having been repeatedly immersed in boiling water, or heavily watered, in order to destroy slugs, &c.); over this place inverted pots or pans, upon which the plants are placed, their elevation being in proportion to the absence of light in front, or its distance above.

If it is necessary to raise the material, place bricks flat-ways at each end across the platform, to the elevation wished for, and add a bead, or curb, on the side next the path; then fill up with Moss, as before; and, in order to give a neat appearance, finish with a surface of coarse river sand or coarse gravel. By watering the surface of these materials an atmosphere will be maintained sufficiently humid for Fuchsias, Calceolarias, Lobelias, &c. &c. to luxuriate in during the early spring months, and capable of counteracting the injurious effect of dry, intense heat.

(To be continued).

ON THE CULTIVATION OF THE FIG.

In compliance with the request of several of my friends, I publish my mode of managing the Fig, for the benefit of amateurs and young beginners; and if the following simple rules are strictly attended to, I am confident that the result must be abundance of delicious fruit with them, as it has been with me here, for the last fourteen years, where there is a good Fig-house, and many plants in pots.

The Fig-wall here is not extensive; but I will commence with it, as it is of greatest importance to the amateur, and those who have little or no glass. I have tried several aspects for the Fig, but I find the south-east to be the best. I have likewise tried several sorts, but, finding them all inferior to the Nerii, I have discarded all others from the open wall. The best soil for this fruit is sandy maiden loam and turf mixed together, without manure of any kind, over-luxuriance being a great evil in their culture. I would advise all who are about to plant a Fig-wall, to form the borders about three feet wide and three feet deep, having a good drainage of any rough material. At the front of this a wall four inches and a half thick, running parallel with the other, should be brought up to within two inches of the surface, the intervening space being walled across, so that each tree may have its own division. This prevents over luxuriance, and causes them to fruit more freely. Any old trees that are growing strong and that do not bear well, might have their roots pruned back, in autumn, and walled in as above described. By doing this early, it would afford the tree time to provide itself with new feeders; and by opening a trench in the front of the wall, about the end of March or beginning of April, and applying a pretty brisk lining of leaves and long litter for a few weeks, it would greatly assist the crop for that season, and establish the trees for the following. Water occasionally with soft water, and after the fruit has attained three-fourths its size, two or three good waterings of liquid manure will assist materially in bringing the fruit to a larger size.

With regard to training, it is of minor importance; but as most people are desirous of having a uniform system, the accompanying figure represents a fine tree of the Nerii; the other exhibits a mode of training equally suitable for the Fig against a wall. The walls here are not flued, and consequently the trees derive no assistance from any but solar heat. My system of pruning is merely to thin the branches where they are too thick, and to admit plenty of light and air. The points of any branches that indicate too luxuriant a growth, are pinched out. The tree will show how young bearing wood is procured when the branches get too long, or begin to have a naked appearance. What I use for covering the Fig in winter is a double thickness of old mats, with a little mulching; a wide coping on the wall is very essential, and a canvas covering drawn over them at night in the early part of their growth is of great benefit to them. If it is desirable to increase the stock, if cuttings of well-ripened wood are taken off in spring, and potted singly in small pots, plunging them in a warm Cucumber-frame, and re-potting them two or three times, they will attain a large size in one summer. With these cuttings, as with the trees at all ages, bottom-heat and water is everything.

Fig. 1.

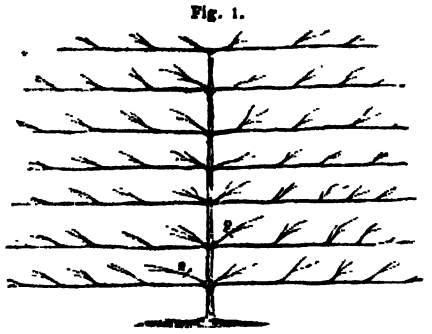

Fig. 3.

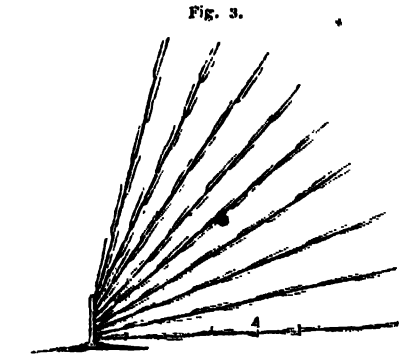

Fig. 1 is taken from a fine tree of Nerii, at Hewell. 2 shows where the long branches are cut back to produce young wood.
Fig. 3 is taken from a fine tree that I had the care of many years since, which looked remarkably well when growing in summer. 4 merely shows where the laterals are tied to the old wood.
